Address on the Medical Work of the Association during its First Decade.—DR. JOHN SHRADY began with a reference to the rôle which a decade is supposed to maintain in the history of individuals, communities, and nations. He said that the Association was the ten-year-old boy, who earned the privilege of staying up late of nights, and of interjecting remarks at the family table; that, like the boy, the Association was too young to be very wicked, and not old enough to be querulous or dictatorial. Still he hoped that while the egotism of the Association was passing muster for enthusiasm, its spirit of decorum might in every sense be exemplary.

He then reviewed the work of the body, its contributions to the different departments of medicine, its recited cases and the set discussions on pneumonia, pulmonary tuberculosis, cancer, etc., which he said, although creditable enough, seemed to attract more attention abroad than at home. In common with other friends, he referred with pride to the Transactions, which had already appeared as a superb series carefully edited and well printed. The address was a long one, in consequence of its historical mode of treatment, but when published would furnish an excellent summary for future reading.

SECOND DAY, TUESDAY, OCTOBER 10TH—MORNING SESSION.

Annual Report of the Council.—This was read by the Secretary, DR. FERGUSON. It contained the reports of the librarian, treasurer, and other officers.

The receipts during the year had amounted to about $4,196. Deducting the expenses, the amount remaining in the general fund was $1,848. That in the library and building fund was $2,643.

Thanks to the Secretary-Treasurer.—On motion, a vote of thanks was tendered Dr. Ferguson for the able and faithful manner in which he had discharged the duties of his office the past ten years.

Amendment to the Constitution.—An amendment to the Constitution, article 2, section 6, offered at the last annual meeting, was read as follows, and adopted. In addition to the foregoing fellows of the Association, delegates not being fellows of the New York State Medical Association may be sent from medical organizations throughout the State in affiliation with this Association, in the proportion of one delegate for each ten members of said subordinate organization. Such delegates shall serve for the annual meeting next succeeding their appointment; they shall be entitled to vote on all questions not involving a change of constitution and by-laws, and shall not be chargeable with any fee or due, though they may secure a copy of the transactions of the meeting at which they served at the cost of extra copies to regular fellows. No medical organization can be entitled to send delegates unless its constitution and by-laws are in harmony with those of the State Association, the same having been approved by the council of this Association, nor shall it be subordinate to any other State medical organization.

Prevention of Disease.—DR. JAMES G. PORTEUS, of Dutchess County, read the paper. People showed greater interest in being cured of disease than in avoiding it. How many of us had ever succeeded in convincing a woman, or a man for that matter, that wearing narrow shoes had anything to do with producing their corns. They might admit the fact in their neighbor's case, but would deny it in their own. People inveighed against dirty water and filthy streets, but at their homes they drank water contaminated with their own excreta, and put up with surroundings which were far from cleanly. It was by persistent and intelligent application and spread of knowledge regarding the causes and the prevention of disease, that most good would be done by the medical profession. The discoveries of Pasteur, Koch, and others, had been of incalculable benefit in the prevention of disease, but the necessity for intelligent application of methods based upon their discoveries was shown by the fact that harm had sometimes resulted from their misapplication. The author impressed the necessity for carrying to a practical conclusion the principles enunciated from our laboratories, whereby we would be enabled, in great degree at least, to stamp out typhoid, diphtheria, cholera, and other infectious or contagious diseases. The question of preventing the spread of tuberculosis received more detailed mention. Dr. Porteus made it a custom to distribute among his clientèle a card with the following printed instructions:

"**To Prevent Consumption.**—Remember that it is an infectious disease communicated principally by the matter coughed up and spit out. The patient should spit in a cup or wide-mouthed bottle, containing a little carbolic acid and water, and frequently washed with hot water. Use carbolic acid and water in commode. Never spit on the street, or floor of house, or cars. Sleep alone, and if possible in an airy and sunny room. Have separate bed and table linen; these should be boiled before washing. Use individual table utensils, washed separately. Wash the mouth twice daily with soda and water. Do not kiss anyone.

"Those who are well should remember that it is an infectious disease, communicated principally by swallowing the germs, by inhaling them, or having them introduced through a wound. Therefore, do not buy or use food that has been handled by a consumptive. Do not share the food or drink of a consumptive. Do not sleep with a consumptive. Do not put coins or small articles in your mouth that may have been handled

by a consumptive. Do not use clothing until it is thoroughly disinfected, if it has been used by a consumptive. Do not kiss anyone on the lips if they have a cough. Do not take food without first washing your hands."

An Additional Note on Nephrotomy and Nephrectomy.—Dr. E. D. Ferguson read the paper, reporting three more cases treated since he had read his last paper. Altogether he had performed nephrotomy and nephrectomy nine times, and, contrary to what was supposed to be the rule, in no instance had he been able to recognize tuberculosis as the cause of the kidney trouble, although later in one case some signs of pulmonary tuberculosis developed. In only one was there a renal calculus. The pyonephrosis had usually had its origin in inflammatory disease below which had travelled upward. Moreover, the cause of the primary inflammation had not in his cases been venereal. In his former cases of nephrotomy he had put a rubber catheter into the wound, but he had come to the conclusion that it was better to insert gauze and keep the wound free, rather than hasten its reduction and have hard tissue form around the rubber tube. By the open method, too, the formation of pus pockets was rendered less liable. One case previously operated upon by nephrotomy required nephrectomy last June, which he thought might have been avoided had the wound been left open. The second of his three recent cases was a primipara at about the third month, in whom abortion was induced and nephrotomy performed for a cystic tumor of a movable kidney. The diagnosis had been confirmed by aspiration. The kidney was anchored during the operation. The patient was soon able to attend to her household duties, the kidney had diminished in size, the wound was still open. The third case was one of pyelitis starting from a vulvo-vaginal, urethral, cystic, and ureteral inflammation. Nephrectomy was preceded by vesico-vaginal fistula performed to relieve vesical tenesmus. The patient was doing well.

About the Condition of the other Kidney.—Dr. John Cronyn had seen a number of cases of nephrotomy and nephrectomy in their hospital at Buffalo, and he had come to the conclusion that the question most in need of solution at present was to determine the condition of the presumably healthy kidney. This fact had been impressed upon him some years ago by the case of a woman suffering, it was supposed, from calculus and pyonephrosis of one kidney alone, there being no tumor nor other evidence of disease in the other kidney. At autopsy the latter was half destroyed by a calculus, while the other kidney contained several calculi, being practically destroyed. He did not think cystoscopy and catheterization of the ureter had yet been very practical.

Dr. T. D. Strong related a recent case of nephrotomy in a young lady whom he had seen in consultation, and in this instance, as in those of the author's, there was no evidence of tubercular origin. The wound was still discharging some fluid.

Exploratory Incision Better than Cystoscopy and Catheterization.—Dr. Ferguson made some closing remarks. In diagnosis he thought it better to resort to an exploratory incision over the kidney than subject the patient to the dangers attending the use of the cystoscope and the catheter in the ureter. It should not be forgotten that the latter were surgical procedures, and the information which they gave us was uncertain.

Introduction of the catheter into the ureter was liable to be attended by carrying up of disease germs and spread of disease from below upward, if the ureter and kidney had previously been healthy, or engrafting upon them new disease, as tuberculosis. Dr. Ferguson preferred exploratory incision in the loin.

Dr. Strong suggested catheterization of the ureter through a supra-pubic exploratory incision into the bladder.

Dr. J. W. S. Gouley agreed with Dr. Ferguson, that an exploratory incision in the loin was preferable to catheterization of the ureter in diagnosis. One might go on to do nephrotomy if necessary, and some weeks later might do nephrectomy.

The Treatment of Epithelioma and Cancroid Ulcers by Topical Application.—Dr. Nelson J. North, of Brooklyn, read a paper in which he gave his experience with lactic acid applied to cancer of the cervix uteri, polypoid growths, epithelioma of the face, etc. Where cancer of the cervix uteri existed he had resorted to this agent only where hysterectomy was impractical or was positively refused. The first patient, with a lacerated and otherwise diseased cervix, had remained in health since the treatment, four years. In the second case there was uterine cancer, more inside than outside the cervix, the lactic-acid applications caused improvement a few weeks, when he heard of the patient's death and learned she had been operated upon by one who first loudly condemned the lactic-acid treatment. Another patient had cancer of the cervix and he recommended cysterectomy, which was performed successfully by Dr. Pilcher, but the disease recurred and soon terminated life. The next case was like the latter, but the patient positively refused to submit to an operation, and therefore the lactic-acid treatment was carried out. Within eight months the uterus had returned to perfect health. The next case was one of polypoid growth in the cervix which, as usual, refused to heal under various applications, but lactic acid had caused the spongy mass to shrink and dry up, only a very small mass remaining. The next case was one of cancer involving the uterus, bladder, etc. Lactic acid relieved most of the subjective symptoms. The next was one of tumor of the arm in a man; repeated applications of the lactic acid caused it to disappear. Another case in which this treatment had proven successful was one of degenerative change in a mole near the nose.

The author thought serious surgical procedures should be avoided whenever possible, especially such as were successful in the operating room only or chiefly. It should be remembered that lactic acid did not act as a caustic, and really was not a caustic. Unless on mucous membranes, its action was limited to the diseased tissue. It penetrated more deeply than a caustic, and seemed to seek out the diseased structure as neither knife nor cautery could do.

Afternoon Session.

Discussion on Lesions of the Pleura.—Dr. John Shrady opened the discussion upon pleural lesions, giving general views and classified opinions without committing himself to any particular recommendations as to treatment. Empyema, he said, had stimulated much controversy, and its treatment was determined in accordance with the usual varying conditions and the convictions of the attendant. The practical part of the subject he would leave for the discussion of the gentlemen to follow him, and who had an ample experience well fortified with statistics and numerous cases.

Question I. What are the Factors of Pleurisy? Its Forms and Contributive Conditions? What are the Pathological Changes in a Case of Progressive Pleurisy Ending in Recovery?—Dr. William McCollom, of Brooklyn, read a paper discussing the first question. Pleurisy, he said, is an exudative adhesive inflammation of the serous membrane lining the thoracic cavity. The contributing causes were several, and the specific cause in a given case was not easily determined, at least not always. The various combinations of symptoms in the several types of the disease, associated, as it frequently was, with other diseases, often allowed it to pass without being diagnosticated. He thought he did not exaggerate when he said that, in at least one-half the autopsies adhesions or exudates were found. Pleurisy was far-reaching in its baneful effects, and was now deservedly receiving increased attention. The author believed that if the diagnosis could be made early the evil after-results could be largely prevented.

Pleurisies were spoken of as dry pleurisy and pleurisy

with effusion. Dry pleurisy might pass to pleurisy with effusion. As to cause, Osler and others were of opinion that more cases were of tubercular origin than had been supposed; when the lung was crippled pulmonary tuberculosis often resulted. When the pyogenic membrane had formed the absorption of pus was not likely to take place, and it was best to leave in a drain. Pathogenic micro-organisms were a prolific cause of inflammatory disease of serous membranes, including the pleura. It should not be forgotten that cold and damp, and taking cold, were the most common predisposing causes of pleuro-pneumonia.

Question II. What are the Points of Differential Diagnosis in Pleurisy and other Affections of the Chest?—Dr. J. Blake White read the first paper on the second question. The diagnosis was rendered difficult by the presence of complicating conditions in the neighborhood of the pleura. When such complications were present it was his experience that little reliance could be placed upon the ordinary symptoms of pleurisy. Individual idiosyncrasy had much to do with the character and intensity of the symptoms. We should not forget that chill was equally indicative of other affections, and might be the primary cause of pleurisy. The liability of those with the gouty and rheumatic diatheses to pleuritic affections should be borne in mind; so also those living in a malarial district, the overworked mentally and physically, the anæmic, and others in reduced health.

Localized pain might be due to disease of neighboring organs. The pain of pleurisy was not infrequently manifested in distant parts. Dyspnœa was an ordinary symptom on which it was not safe to rely, although when associated with cough it was a valuable indication. The dyspnœa seemed of a double nature—inability to breathe from mechanical hindrance, and dread of pain. In diaphragmatic pleurisy there were symptoms referable to the digestive system, and hiccough. Constant desire to clear the throat when there was no throat lesion, was almost pathognomonic of dry pleurisy. A quick attempt to clear the throat pointed to adhesion higher, a prolonged attempt pointed to adhesion lower or at the base. At a later stage the diagnosis was usually easy by auscultation and percussion. A change of friction into creaking was more common in disease of the pericardium than of the pleura. One could auscultate to better advantage by having the patient expire quickly, as in blowing out a candle. In pleurodynia the pain was more of the nature of a catch in respiration than the darting pain of pleurisy, and a hypodermic of morphine and atropia would in the former give almost immediate relief. No investigation could conclusively prove that a micro-organism was the cause of a given pleurisy. The presence of micro-organisms did not show causative relation. It was just as easy to prove that they were the result of the pathogenic process as the cause. We could not trust to the discovery of bacteria in diagnosis.

Dr. John G. Truax, of New York, also read a paper upon the second question. He first went over the physical signs attending the different forms of pleurisy. There was a sound which, when it could be heard, was almost conclusive evidence of the presence of lymph—the friction sound or pleuritic rubbing. Some of its peculiarities were, that it could not usually be heard over a large part of the chest-wall at one time; it was seldom present at one spot for a long time; it changed as new pleura became involved; it could be felt as well as heard; sometimes it was brought out only on deep inspiration; effusion of liquid destroyed it; it was most apt to be heard first in the region of the axilla or below the nipple; it might be heard a few hours after the commencement of dry pleurisy and continue weeks; experience was required to recognize it or distinguish it from bronchial crepitation.

Pain was the first symptom of which the patient complained. Chest movements were much diminished, the respirations were short and jerking. In most cases liquid was effused in great quantity and rapidly. At first it was non-purulent, but later it became thicker, more opaque with leucocytes, when it constituted empyema. When there was a large quantity of liquid, percussion and auscultation showed complete absence of resonance and respiratory murmur. If the lung had been bound down by free pleuritic adhesions, bronchial breathing might be heard even though there was a large quantity of fluid. Change of position of the patient would aid in the diagnosis. Old pleuritic adhesions might prevent liquid from gravitating to the most dependent part of the chest-cavity, but the fluid would always gravitate to the lowest part of the cavity in which it was confined. Pressure of the liquid upon the heart and blood-vessels might give rise to signs which would lead one to suspect complications which did not exist. The author referred briefly to other symptoms—change or loss of voice sounds, bronchophony, egophony, dyspnœa, cough seldom absent, pyrexia generally moderate. The author left unread that portion of his paper naming the conditions with which pleurisy might be confounded, as the ground had been covered by Dr. White.

The Surgical Treatment of Pulmonary Cavities.—Dr. N. P. Dandridge, of Cincinnati, read the paper. There was a disposition on the part of some to push surgical treatment of pulmonary cavities beyond reason; others showed too much conservatism. Experiments upon animals showed that a considerable portion of the lungs could be removed without danger to life or health; while such experiments had undoubtedly been of great service to man, they had at times led to operative interference beyond the bounds of reason and safety. The fact that the patient survived the operation did not prove that he could not have done without it, or that it had been beneficial. The complete removal of a limited lesion, when possible, relieved the patient of his trouble and restored him more or less nearly to health; on the other hand, removal of a local lesion in a generalized or diffused disease must be an incomplete procedure, yet it might prove of limited benefit. For instance, it was often of value to drain a cavity of decomposing matter, as the surgeon would do in any other portion of the body when it was impossible to remove the diseased tissue. Among the conditions mentioned, in which it was possible for drainage to prove of value, were pulmonary gangrene, hydatid cysts, tubercular cavities, bronchiectatic cavities, and pyo-pneumothorax. Exaggerated claims for operative interference were strongly deprecated. After reviewing some of the experiences of others, the author related a few cases in which he had himself drained pulmonary cavities with benefit. The first one was that of a man suffering from pulmonary tuberculosis, and who gave a strong family history of that disease. Physicians who had seen him introduced an aspirating needle over supposed empyemic fluid, but obtained only blood. Dr. Dandridge resected the eighth and ninth ribs and let out blood-stained purulent fluid, from what he believed was a phthisical cavity, inserted a drain, and when the patient left, at the end of two months, there was very marked improvement, although the physical signs at the apex had not changed. It was one of the best cases for drainage—a superficial tubercular cavity. Such a condition was likely to be mistaken for a localized empyema. Another case was one of pleurisy with a fistulous connection between the cavity and a bronchial tube. Purulent matter had been expectorated for some time. He decided to freely open the pleural cavity, after which he traced the fistulous tract upward, introduced a large drainage-tube, irrigated. The man's condition improved and he passed from under observation, but he had heard there was now amyloid degeneration of other organs. The operative treatment of hydatid lungs resulted in a large proportion of recoveries.

The following were the conclusions arrived at: A certain number of cavities of the lungs can be successfully dealt with by incision and drainage, and if a complete cure does not result, at least sufficient benefit is likely to follow the diminution of the amount of purulent expec-

toration and septic absorption to justify the attempt. Superficial phthisical cavities at the base should be opened if the general condition of the patient allowed. Cavities at the apex should only be opened when free and persistent fetid expectoration is present, resisting treatment, and the rest of the lung is not involved. Abscesses, gangrene, and hydatid cysts should be opened and drained whenever they can be located. Cavities that have been opened are generally best treated by packing with gauze, preferably with iodoform. A further trial of such agents as iodoform, chlorine gas, and chloride of zinc is desirable to determine whether they may not modify tubercular infiltration in the walls of cavities. It is very desirable, for the further extension of surgical interference in pulmonary cavities, that the means of exactly locating these cavities and defining their size, and character of the tissue which overlies them, should be further studied. For the accomplishment of this purpose the surgeon must look to the physician.

Question III. What is the Treatment of Empyema, with Relative Value of Aspiration, Rib Resection, and Free Opening with Drainage?—Dr. Charles A. Leale, of New York, continued the discussion on pleurisy with a paper. The great variety of the lesions found post mortem in pleurisy showed the difficulty or impossibility of making fixed surgical rules in treatment. He had made many observations which proved that the entire lung might be destroyed or rendered useless, and that fully one-half of the remaining lung might be diseased, and the patient live in comfort by observing moderate rest. A striking instance was that of a man who lost some members of his family by pulmonary phthisis, and at the urgent advice of his physician, who recognized cavities in his lungs, gave up business and made a change of climate, going to Egypt. There he lived in comfort for years, and came to give his advisers no credit, but said they were mistaken in their diagnosis. Once he ate too freely, the distended stomach pressed upon the diaphragm, through the influence of the adhesions excessive coughing started, an atheromatous artery of the brain burst, and death ensued. At autopsy the pulmonary lesions were found walled in, as had been predicted.

His personal experience was that, where the pus in empyema was laudable one removal sufficed for a cure, but where the pus was putrid free drainage was called for.

The discussion upon the papers relating to pleurisy was participated in by Drs. Manley, Cronyn, Ferguson, Donald McLean, Dandridge, and Leale.

Dr. Manley opposed aspiration. He had employed it up to the time of the discussion in Paris when Verneuil took strong ground against it as being injurious. Dr. Manley then found, on looking up the histories of his cases in which he had aspirated, that none had lived longer than three years. He believed opening the pleural cavity was always a serious operation. Nature's method of draining an empyemic cavity was best, but when she failed it was necessary to introduce artificial drainage.

Dr. John Cronyn thought the pleural cavity with serous effusion could be aspirated safely by a clean instrument, avoiding the introduction of air. Pus must become poisonous or suppurative before it could become dangerous. The old valvular method of drainage should be applied. In treatment of pleurisy he employed dry or wet cups, topical applications (poultices), pure opium to relieve pain, not the alkaloids. Referring to the prevention of tuberculosis, he said the common habit of recommending slight girls to marry strong men was dangerous to the men, and he cited instances where the husband, contracting tuberculosis from the wife, died.

Dr. E. D. Ferguson spoke of the value of drainage in pyo-pneumothorax. Often the removal of but very little of the pus by aspiration would effect a cure. There was only a small proportion of cases in which rib resection was called for. When indicated, the outlook for the patient was not hopeful.

Dr. Donald McLean, of Detroit, said the aspirating needle might be useful in diagnosis, yet it was like a broken reed. In getting rid of fluid he would resort to some more radical measure, say excision of rib, to secure free drainage. He had not met with any disaster following it.

Dr. Dandridge favored resection of rib where drainage was indicated. There was some advantage in early aspiration by its influence on the expansion of the lung, for air not entering where the fluid had existed, the lung expanded to fill the space.

Dr. Leale related a case of metastatic tuberculosis to the brain in a strong man, who acquired the disease from a wife whose family was tubercular.

An Ancient Catheter.—Dr. J. W. S. Gouley presented a catheter from the remains of Pompeii. It was of copper, covered by verdigris, of sigmoid form, had the vesical opening near the extremity. Similar catheters were described by Celsius, and the rules which he gave for their introduction were useful to-day.

Dr. Gouley also showed some domestic catheters, and said there were two firms in this country who made as good instruments as were imported from abroad. Indeed one firm made better gum and rubber catheters by machinery than the English catheters which were made by hand. They had a very high polish.

Evening Session.

Remarks on Fermentative Dyspepsia.—Dr. Austin Flint read a paper upon Fermentative Dyspepsia, including only functional cases, or those without organic lesion. All such cases of dyspepsia were accompanied by a certain amount of mental or moral disturbance, and although the person might be well nourished, it was desirable and important to relieve him of his symptoms. He believed that all forms of flatulence were due to a micro-organism, although its exact action upon the food within the alimentary tract might not be easy to explain. He regarded the process of digestion as too complicated for man to introduce a substitute into the stomach which should relieve the digestive fluids of their work. Pepsin, pancreatin, etc., were regarded by him as worthless when introduced into the digestive tract. His condemnation of them did not exclude peptonized or partially digested foods before these were eaten. Having come to regard fermentation in the alimentary tract as due to microbes, he had made this his basis in the search for a remedy against flatulent dyspepsia. Salicin, which had been recommended highly by his father, had proven useful in his hands, but he had found another agent more uniformly successful, namely, bismuth subgallic. Of this he gave five grains before or after meals, according to the case, preferably in tablets, or in capsules. It had been almost uniformly successful.

Dr. John Cronyn thought the chief question was not the remedy, but what was the nature of the disease. He related his own experience during an attack of dyspepsia, for which the doctors prescribed several remedies without success, and then finding evidence that the juices of his stomach were not sufficiently acid, he took hydrochloric acid and was relieved.

Dr. Henry F. W. Risch, of Brooklyn, had observed that flatulence was of two forms, namely, that due to decomposition of nitrogenous foods, and that due to fermentation of carbo-hydrates. The former was distinguished from the latter by the foul-smelling breath. In the former he stopped putrefaction by prohibiting meat and nitrogenous elements, and limiting the patient to carbo-hydrates; in the other form the opposite rule was followed. Further measures were, an emetic of ipecac and warm water stomach washings if the doctor had time, acids, pepsin, etc.

Dr. C. A. Leale, of New York, referred to experience with the Floating Hospital for Children, and said he had been struck by the important rôle played by micro-organisms in the production of diarrhœa and indigestion, so that it had come to be the rule to wash out

the colon and give only sterilized or boiled milk. The improvement was rapid and remarkable. He had learned of the value of salicin from the elder Flint. Bismuth was useful in children.

Bloodless Amputation at the Hip-joint; A Record of Cases Operated upon by the Author's Method.—Dr. John A. Wyeth, of New York, read this paper. The first part was devoted to a brief historical review of attempts to render amputation at the hip joint a bloodless operation. It had been only about four years since the author had first operated in the manner about to be described, and since that time he had collected thirty-nine cases. Under strict antisepsis the operative technique was as follows:

1. With the patient in the usual position for hip joint amputation, the limb should be emptied of blood either by elevation of the foot and lowering the trunk, or by the Esmarch bandage applied from the toes to the trunk. Under certain conditions the bandage can be only partially applied, or may not be applied at all. When a tumor exists, or when septic infiltration is present, pressure should not be exercised quite to the diseased portion for fear of driving septic matter into the vessels. In injuries with great destruction, crushing, or pulpification, of course the Esmarch bandage is not applicable, and one must trust to elevation to save as much blood as possible.

2. While the member is elevated, or before the Esmarch bandage is removed, the rubber-tube constrictor is applied. The object of this constriction, and it is the chief point in the method, is to have absolute occlusion of every vessel at the level of the hip-joint above the field of operation. To prevent any possibility of the tourniquet slipping, I employ two large mattress-needles, or skewers, about three-sixteenths of an inch below the anterior superior spine of the ilium, and slightly to the inner side of this prominence, and it is made to traverse superficially the muscles and fascia on the outer side of the hip, coming out on a level with and about three inches from the point of entrance. The point of the second, smaller needle, is entered one inch below the level of the crotch, internal to the saphenous opening, and, passing squarely through the adductors, comes out an inch below the tuber ischii. The points are shielded at once by bits of cork to prevent injury to the hands of the operator. No vessels are injured by these skewers. A piece of strong white-rubber tube, one half inch in diameter, and long enough when tightened to go five or six times around the thigh, is now wound very tightly around and above the fixation needles and tied. If the Esmarch bandage has been used it is now removed.

3. In the formation of flaps the surgeon must be guided by the condition of the parts in the field of operation. When permissible the following method seems advisable: About six inches below the tourniquet a circular incision is made, and this is joined by the longitudinal incision commencing at the tourniquet and passing over the trochanter major. A cuff, containing the subcutaneous tissue down to the fascia, is dissected off to near the level of the trochanter minor. At about the level of the trochanter minor the remaining soft parts, together with the remaining blood-vessels, are divided down to the bone by a circular cut, and in order to facilitate the search for the vessels the soft parts are rapidly removed from the femur for several inches below the line of the divided muscles. At this stage of the operation the larger vessels, veins as well as arteries, can be tied with good sized catgut. As suggested by Professor Murdoch, of Pittsburg, he now left the entire extremity intact, and used the full length of the limb as a lever in dislodging the head of the bone When the larger and easily recognized vessels have been secured, the muscular attachments of the upper extremity of the bone are removed with the scissors or knife, keeping along very close to the bone.

Holding the soft parts away with retractors, the capsular ligament is exposed and divided in its circumference.

Forcible elevation, abduction, and adduction of the thigh permits the entrance of air into the socket, and at the same time ruptures the ligamentum teres, and the dislocation is then easily and rapidly effected. Properly conducted up to this point, not a drop of blood has escaped except that which was in the limb below where the constriction was applied. If now the tourniquet be carefully and gradually loosened, each bleeding point may be easily determined and the forceps applied as required, until the tube is entirely removed.

4. The closure of the wound with the usual precaution of drainage remains. Dr. Wyeth preferred silk-worm-gut; one good-sized rubber drain from the acetabulum passed out at the most dependent part of the wound. When by reason of proximity of epithelioma or destruction of parts, use a modified method.

The author had been able to secure statistics of thirty nine amputations by the foregoing method. There had been a death-rate of 23.7 per cent. (five were reamputations); sarcoma, 16 cases, 2 deaths, 12.5 per cent.; inflammatory bone diseases, 18 cases, 3 deaths, 16.6 per cent.; violence, 4 cases, 4 deaths, 100 per cent., all very severe and extensive injuries; nerve injury, one, no death. Thus it would be seen that there had been thirty-five amputations for disease with five deaths, 14.2 per cent.; four amputations for injuries and four deaths. This was in marked contrast with Ashurst's list of 633 cases with a mortality of sixty-four per cent. It was not claimed, however, that the reduced mortality-rate was due entirely to avoidance of hemorrhage which this method implied. Antiseptics, etc., had something to do with it. By this method bleeding could be as successfully controlled as in amputation of the thigh at any point below.

Dr. Joseph D. Bryant said the results of this method spoke for themselves. Dr. Wyeth was to be congratulated for devising the means by which hemorrhage in amputation in the hip-joint could be so successfully controlled.

Dr. Donald McLean, of Detroit, said he appreciated Dr. Wyeth's method of controlling hemorrhage, but he must express the conviction, with due modesty, that there was even a better method, which was to make pressure upon the abdominal aorta by means of a tourniquet. He had operated, controlling hemorrhage in this manner, a number of times with entire satisfaction. Scarcely a drop of blood need be lost.

Dr. Reginald H. Sayre, of New York, feared the skewer would, in some cases at least, be too near the line of incision.

Dr. Wyeth said the technique of the procedure which he had described was applicable in all cases. He had operated in nine minutes.

The Treatment of Angular Deformities of the Hip-joint.—Dr. Reginald H. Sayre, of New York, prefaced his remarks on this subject by the statement that the best thing was to prevent angular deformity by proper treatment at the outset. In any case of hip joint disease there should be recovery, if the recovery took place at all, with the legs parallel. The treatment varied with the nature of the disease and the condition of the joint when seen. The history of a few illustrative cases was given. Bony anchylosis sometimes existed when it was supposed to be fibrous, and *vice versa*. When bony union existed, attempts at motion would not produce pain. The contrary was likely to occur when there was fibrous union, although the motion was very slight. In many cases the use of some force would break up the attachments, and by degrees we would succeed in securing a fair amount of motion. In other instances we had to resort to osteotomy.

Third Day, Wednesday, October 11th — Morning Session.

Opposed to a Change in the Code.—The Secretary offered the following resolution: In reply to the notice of the American Medical Association requesting that the

State medical organizations in affiliation with that body express their wish in reference to any changes in the Code of Ethics, the New York Medical Association has to say that it has made that Code one of its foundation-stones, and it is entirely opposed to any alteration therein. This is the result of a full reconsideration of the subject, and after an experience of ten years of organization under that Code. The resolution was adopted without a dissenting voice.

Treatment Indicated after Trachelorrhaphy.—Dr. William H. Robb said that in the majority of cases trachelorrhaphy restored the parts to their normal condition and the patient to health. In a few instances, however, this result did not follow, and in order to trace the reason therefor, Dr. Robb described briefly the anatomy of the pelvic organs, especially of the uterus, the changes which take place during pregnancy and subsequent involution. Laceration of the cervix, when of sufficient severity, left the womb in a state of subinvolution, and was followed by various pathological changes in the cervix and neighboring parts. Treatment after trachelorrhaphy was general and local. Of many drugs, he wished to mention two from which he had obtained particularly good results when administered internally—they were mercury and iodide of potassium. The local treatment required the patient to be put to bed, position, hot douches, glyceride tampon, tincture of iodine, abstraction of blood from the cervix, etc.

Three months of this treatment often started an improvement which terminated in recovery. The condition most frequently found in his practice had been endometritis, often complicated with fungous degeneration. Scraping of the entire endometrium and draining with gauze were indicated. In case of inflammatory pelvic deposit galvanism had spared the necessity for abdominal section. If there were imperfect union of the cervix a second operation would be called for. When all treat ment failed, the woman could be promised removal of the appendages after the menopause.

Dr. A. Palmer Dudley, of New York, thought that if the after treatment described by Dr. Robb were carried out before trachelorrhaphy, there would be no failures from the operation itself. Then, in repairing the cervix, he divided the uterine artery on both sides and ligated it with the sutures, so that the blood-supply to the hyperplastic organ was cut off during about forty days. By that time great reduction in size had ensued. In the preliminary treatment of the diseased and enlarged uterus he touched the parts with pure carbolic acid. Free drainage was essential. He advised that the cervix be repaired immediately after labor where possible. He had done this in a few cases, employing reflected light.

Dr. Robb said slight lacerations of the cervix healed without any operation, and Dr. Ferguson doubted whether immediate repair would be an easy procedure in primipara.

Voluntary Commitment of the Insane to Asylums.—Dr. W. D. Granger sent the paper, which was read by the Secretary. Up to recent times asylums for the insane had been merely places of incarceration—prisons, the superintendent being looked upon as the jailer. Happily, a change was rapidly taking place, and such institutions were very properly coming to be looked upon as hospitals. Many patients realized their condition and wished, as did their friends, that they might enter the hospital for treatment if the odium of incarceration could be removed.

In some State institutions (Connecticut and Massachusetts) voluntary commitment was provided for under certain restrictions. In New York there was a similar provision in regard to homes for the insane, but in State institutions a legal commitment was called for, and the patient could not leave the hospital at will. The superiority of voluntary commitment in certain cases was striking, and it made provision for a class of patients who, under the technicalities of the law, were not admitted to the State asylums at all. It was in cases on the border line of insanity that voluntary commitment was most needed and proved most useful.

The paper was discussed by Drs. Lester, Colvin, Ferguson, McLeod, and Strong. Dr. Lester gave an instance of injustice in the working of the new law, but others explained that this was due to the rules established by the Commissioners in Lunacy or obstinacy of the asylum superintendent, and not to any fault in the legislative enactment.

The Treatment of Enteric Fever.—Dr. Gustavus Eliot, of New Haven, Conn., in presenting this paper, said he had nothing new to offer, but wished to impress the superiority of certain recognized methods over others. The patient should be put to bed and not be allowed to get up until all doubt was ended as to the nature of his disease, or until recovery, if it were really typhoid. Fresh cow's milk was the best food. Give at least two quarts a day. There were some therapeutic annihilists; to them he did not address his further remarks. He advised three to five doses of ten grains of calomel at the outset, with forty-eight hours' interval. Quinine might be given if one suspected malaria, but probably nine cases out of ten would be as well off without it as with it. Salol had been proven to be without value. Turpentine was useful in tympanites, and it strengthened the nervous system. He used iodine and carbolic acid. They should be administered early, and might be continued until convalescence. As to the Brandt or tub-bath method, he ventured to say it would never be carried out in country districts. Those who applied it must turn a deaf ear to the piteous appeals of the sick to be spared the discomfort. Antipyrin and other similar antipyretics had undoubtedly been the means of saving many lives in enteric fever. Stimulants were seldom indicated at the beginning, and should not be given by routine.

Dr. Douglas deprecated the too free use of stimulants in typhoid. Among agents used by him were creosote and calcined magnesia; ten grains of calomel repeated not oftener than three times; salicin; no quinine unless there were malaria; subnitrate of bismuth often took the place of opium.

Dr. William Finder took the fat from milk when the pure article could not be digested. Resorcin was valuable.

Dr. Lester said malaria prevailed where he lived, and it was at times difficult to decide whether the patient was suffering from this affection or typhoid. Quinine was apt to be useful, and doctors from a distance, when called in consultation, were apt to err in prohibiting its use.

Dr. E. R. Squibb, of Brooklyn, said he never lost opportunity to repeat the fact that calomel was converted into an albuminate in the stomach, but a small amount became bichloride and was perhaps antiseptic in the intestine. If there were much fluid in the stomach it was apt to be carried along too fast. Take the dry powder on the tongue.

Dr. Martin gave no quinine, as there was no malaria where he lived. Feed the patient.

Rare Forms of Gout and Rheumatism.—Sir James A. Grant, of Ottawa, stated by way of preface to his paper, that in Canada they watched with the greatest interest the work of the medical profession in the States. It was gratifying in the highest degree to con over such names as Rush, McDowell, Gross, and a host of others. He then gave the histories of some cases of rare forms of gout and rheumatism, one being a case of pneumonic gout, one of gouty perityphlitis, another of rheumatic typhlitis or perityphlitis, in each instance the pneumonic or typhlitic symptoms disappearing with metastasis of the diathetic disease to the joints. Let the people be educated to simplicity of living, so that the functions of the body might be carried on in a normal and healthful manner.

Surgical and Pathological Memoranda.—Dr. Donald McLean, of Detroit, related some interesting cases from a surgical and pathological stand-point. Some were cases of ununited fractures of long bones. It seemed the chief

cause of non-union in such cases had commonly been overlooked, *i.e.*, that the blow producing the fracture had been direct and severe. In all old cases his treatment had come to be limited to two procedures: If possible, application of a splint or support; or amputation and an artificial limb. In amputation at the hip-joint he rendered the parts bloodless by a tourniquet compressing the abdominal aorta beneath the umbilicus. One case of hip-joint amputation following a severe injury was related, the patient recovering. He also related two or more cases of amputation of the whole shoulder after ligating the main vessels. Two well-marked cases of spina bifida had come under his care in which treatment by iodine injections followed by excision of an elliptical flap effected a cure. Two cases of tumor of the median nerve of the arm were cited in which he performed excision successfully, in one the tumor proving to be a cyst as large as an orange. In both of these cases the patients were chloroformed and went into collapse from which it was difficult to arouse them, causing him greater anxiety than he had ever before experienced during thirty years' use of this anæsthetic. Eleven years ago he amputated the breast of a patient for scirrhous cancer, the diagnosis being confirmed clinically and microscopically. There had not been any return. Five years ago he amputated her son's tongue for carcinoma and there had been no return. The reader showed a large and very irregular gold plate which a man had swallowed while asleep, and which by good luck he caught with the forceps introduced some five inches down the œsophagus and extracted it. One could not conceive of a form in which the foreign body would have been more difficult to remove, yet, as it happened, little trouble was experienced.

Discussion on the Treatment of Appendicitis.—Dr. Frederic S. Dennis, of New York, read a paper, opening the discussion, in which he propounded the following questions: 1. What proportion of cases of appendicitis end in resolution? 2. What class of cases require immediate operation? 3. What class of cases do not require immediate operation?

To formulate precise and satisfactory answers to these questions was not an easy task. There was no unanimity of opinion as to the exact time when an operation should be performed. During the last two years the pendulum had swung so far in one direction that it had begun to swing in the opposite direction. There was an honest diversity of opinion, it tending on one side toward extreme radicalism, on the other toward extreme conservatism. About one-half to two thirds of cases of inflammation in the right iliac fossa underwent resolution. An immediate operation was called for if the symptoms went on after the third day; an immediate operation was not called for if, after the second or third day there was general subsidence of all the symptoms. There were, of course, exceptions to all general rules in surgery, and he could conceive of cases where an operation was called for within twenty-four hours.

It should be remembered that there were several varieties of inflammation in the right iliac fossa independent of appendicitis. Then it had been argued in favor of interference that removal of the appendix removed the possibility of subsequent appendicitis. As a matter of fact, however, there had been cases in which the attacks continued after removal of the appendix. It should be remembered, too, that there were many other conditions which had been mistaken for appendicitis, and in which abdominal section would have done harm. Then there was great liability of hernia following the operation. A prominent instrument-maker said he had sold six dozen trusses during the last year for hernia following operations upon appendicitis. McBurney's point was a valuable sign, yet it was sometimes present where appendicitis did not exist.

Dr. J. W. S. Gouley had seen in all about two dozen cases of appendicitis which ended in resolution, and only two or three which had come to operation, and then successfully. They were perityphlitic or typhlitic.

Dr. Donald McLean, of Detroit, related some interesting cases in his city, which showed that the questions were of the most serious which we were called upon to answer. In some, an operation had been recommended, was rejected, and the patients got well; in others, an operation had been done and death ensued: in still others it had been followed by recovery. The eyes of a critical public were upon the profession in this matter. In one instance he opened the abdomen at the request of a girl who had long suffered from a "pain in the side," and was about to give up his search for the cause when he happened to feel a band, and tracing it up it was found to be an elongated appendix vermiformis which had become adherent to the inflamed ovary.

Dr. Joseph D. Bryant said there was a difference between the questions, what proportion of cases of appendicitis ended in resolution? and what proportion of cases of pelvic inflammation ended in resolution? The answer to the former question, however, could only be estimated from that of the latter. According to Fitch about fifty per cent. of cases of inflammation about the caput coli ended in resolution. But could a case recover by resolution if there were gangrene of the appendix? or perforation? or abscess? He thought not in the sense of complete recovery. Then in what percentage of cases of inflammation in the right iliac region did abscess, gangrene, and perforation take place? He was asking questions which he was himself unable to answer. Again, could we diagnosticate gangrene, abscess, and perforation in time to do an operation? Assuming from the history of a case that one of these conditions was present, he would operate at once, whether the case were one day or several days old.

Temperature was an unreliable guide, continuous local pain and tenderness, muscular rigidity, and tympanites were important signs of perforation. Regarding the McBurney point, it was valuable when present, but to expect pain in this particular place was unreasonable, as autopsies had shown that the caput coli varied greatly in locality.

Dr. John A. Wyeth thought that where one was in doubt it was safer for the patient to operate. Nor did he think that he was biased in favor of interference. True, many cases got well by resolution, but suppose there were one hundred persons with appendicitis on the right hand and one hundred on the left; that all the former were operated upon by an able surgeon, while the latter were not: which list would show the largest proportion of recoveries? As to hernia, it was due to late operations, the presence of suppuration, and inability to close the wound. With a timely early operation the wound could be closed and hernia avoided.

Dr. E. D. Ferguson's experience had been that inflammation in the neighborhood of the caput coli usually ended in resolution, but sometimes operative interference had been necessary. His only two cases of death had been where the patients refused an operation. Do not spend much time searching for the appendix. An immediate operation was called for where there was diffuse peritonitis or perforation of the unprotected appendix.

Dr. W. T. Lusk said a word from the medical side. He thought we had about reached a stage in the history of appendicitis that we had reached not long ago in the history of salpingitis. It was once said that no pus-tube could recover; all cases should be operated upon. Lately numerous examples were being put on record of recovery without operation. People were often unnecessarily frightened on having even a simple colic, being told, perhaps, by some radical surgeon, like in an instance which he related, that if it were their own case they would submit to an operation at once.

Dr. John Cronyn made some remarks upon Sir James A. Grant's paper, after which a communication was read from a French physician, visiting this country, on granular conditions of the eyes in tropical climates. He having found a strong solution of sulphate of copper about the only efficient means of healing them.

FOURTH DAY, THURSDAY, OCTOBER 12TH.

President-elect.—The Nominating Committee made its report. Dr. Thomas D. Strong, of Chautauqua County, being named for President. The gentlemen named were elected.

The Male Catheter, with Some Observations Upon the Proper Mode of Introduction into the Bladder.—DR. DOUGLAS AYRES read the paper referring to ancient use of the catheter, its forms, the anatomy of the urethra, steps in introduction of the catheter, difficulties encountered, and relating cases of failure in his neighborhood.

Researches on the Efficacy of Vaccina after Typhoid Fever.—DR. WILLIAM FINDER, JR., of Troy, had observed, during an epidemic of small pox at Troy, about twelve years ago, that patients who had had typhoid fever were easily vaccinated by the same matter which failed in other cases of revaccination. It seemed that typhoid destroyed the efficacy of vaccina, and he had since made it a rule to revaccinate in all cases of typhoid.

DR. ROBE remarked upon the necessity for using fresh vaccine, and related an experience in his neighborhood.

Reflections on the Need of Close Observation of Disease and upon the Value of Hygienic Therapeutics.—DR. H. ERNST SCHMID, of Westchester County, read a paper with this title. A few ancient and modern stories were cited as forcible illustrations. In most of them the information seemed to have been derived through marked power to draw inferences more than through observation. Some ridiculous mistakes were also mentioned, one or two in the experience of Wünderlich. Allusion was made to the injustice of the criticisms of the laity. If it were fair to sue a doctor for failure in a given case, where he had treated the patient to the best of his ability, why should not the lawyer be liable when he lost his client's case through a legal technicality? Medicine had for a long time been mere empiricism; a groping in the dark. Let there be more general recognition of the health-preserving and healing influences of fresh air, proper nourishment, out-of door exercise, cleanliness, hygiene. Success in medicine called for knowledge, thoroughness, experience, and boldness, which was based upon profound judgment and conscientiousness.

State Asylums for the Inebriate.—DR. SCHMID, as a member of a committee appointed last year, said they had gone before the Legislature and asked for the establishment of hospitals for the inebriate, similar to those for the insane, and a bill had been passed by both the Assembly and Senate, but had been vetoed by the Governor. It was hoped to have the bill passed again and signed. The committee was continued.

Puerperal Blindness.—DR. DARWIN COLVIN read the history of a case of puerperal blindness which, he thought, could have been warded off if the attending physician had followed his advice strictly and abstracted blood earlier. He believed the cause of the blindness and eclampsia was the same. The woman recovered from her labor and slowly regained sight.

DR. MCGILLICUDDY had four cases of puerperal blindness in hospital practice, the eclampsia being controlled by chloroform and other anæsthetics, milk diet, large quantities of water, etc. The treatment directed against the condition of the kidneys had in a few days relieved both blindness and eclampsia. In addition, delivery was effected at once.

A Plea for the Non-operative Method of Treating Dysmenorrhœa, Pelvic Inflammation, and Pelvic Abscess.—DR. T. J. MCGILLICUDDY, of New York, read an earnest plea for the treatment of dysmenorrhœa, pelvic inflammation, and pelvic abscess, by measures directed to the alimentary tract from above and below, and by non-operative intra-vaginal methods. Many had declaimed against too much pelvic surgery, but had stopped there instead of going on to offer an efficient substitute. The measures, described at some detail in the paper, related to depletion of the pelvic vessels, large quantities of hot water taken into the stomach, use of nitrogenous food, refraining from hydrocarbons; iron, quinine, arsenic, dilute muriatic acid, intestinal antiseptics, bitter tonics, douching the colon twice daily, vaginal douches and tampons, rest, hygienic surroundings. Many were the cases of pelvic inflammation, dysmenorrhœa, and even abscesses, which had been cured by such means. Surgical interference with the interior of the uterus had done much harm. If a patient died from an operation where medical treatment would have cured, the white sheet covered a scientific murder.

A Discourse on Temperature.—DR. H. F. W. RISCH, of Brooklyn, gave an abstract of a paper on this subject. The uniformity of the temperature of the human body at all latitudes was a most remarkable phenomenon, and its disturbance pointed to some form of irritation, mechanical or chemical. The irritation was of the nervous system. We should try to reduce the temperature to normal, not by applications to the outside of the body if the rise was on the interior, but by colon flushings and by removing the cause, for instance microbes or their products.

Wednesday evening a banquet was held at the Hotel Brunswick. Thursday afternoon a visit was made to the Island hospitals.

Pan-American Medical Congress.

First Meeting, Held at Washington, D. C., September 5, 6, 7, and 8, 1893.

(Special Report to the MEDICAL RECORD.)

(Continued from p. 502.)

SECTION ON HYGIENE, CLIMATOLOGY, AND DEMOGRAPHY.

ALBERT L. GIHON, M.D., MEDICAL DIRECTOR, U. S. N., WASHINGTON, PRESIDENT, IN THE CHAIR; ENGLISH SECRETARY, PETER H. BRYCE, M.D., TORONTO, CANADA; SPANISH SECRETARY, PEDRO JOSÉ SALICRUP, M.D., NEW YORK CITY.

FOURTH DAY, FRIDAY, SEPTEMBER 8TH—MORNING SESSION.

Pestilential Conditions.—The combined sections were called to order at 10 o'clock, when DR. BELL opened the proceedings of the day by reading his paper entitled "Pestilential Conditions."

Modern sanitation, he said, as undertaken in England, fifty-five years ago, was based upon the recognition of local conditions to the death-rate of the people; and the coincidence of its practice and the progressive reduction of the death-rate ever since, is the unanswerable argument for the establishment of sanitary methods everywhere.

Dr. Bell passed in review on London in the sixteenth century, and Cairo two centuries later, discussing their pestilential conditions and the fearful results.

Cholera in India received able and timely attention. He quoted from the valuable work of Dr. M. C. Furnell, late Surgeon-General and Sanitary Commissioner, Madras, as follows:

"In all India there died during 1879, 5,000,000 of people, of whom fever killed 3,500,000; cholera killed off 265,000. In some years it is much worse than this. A good deal of this mortality is preventable, and the use of impure water is, I feel persuaded, answerable for much of it."

Following a lengthy description of the Indian conditions that foster the disease, he further quoted from the same practical authority as follows:

". . . I do not by any means maintain water is the only means by which the cholera is spread. . . . I believe the air, clothes, food, drink of all sorts besides water, may and do spread it; but I also believe that water is the chief means by which it is spread, especially in India, and that on account of the peculiar treatment

water obtains in this country, that India, the only country in the world, is subject to such frequently recurring and such terrible epidemics of this dread scourge."

Germs and germ disease received due attention. Dr. Bell said: "But the spores of bacteria—the seeds—are, of all things viable, the most persistent. . . . The spores of bacteria are practically immortal."

Next in order was No. 702 on the official catalogue, or, "Epidemic and Exotic Diseases Propagated by Shipping;" "What Diseases Should be Quarantined?" "Responsibility of Nations for Epidemics;" "India for Cholera, South America for Yellow Fever;" "Can a Feasible Plan be Devised to Totally Exterminate Cholera?" "International Intervention to Prevent the Propagation of Cholera or other Epidemic Diseases by Pilgrimages or Immigration."

Discussion opened by Wolfred Nelson, M.D., New York City.

Dr. Nelson said that Surgeon-General Wyman, of the United States Marine Hospital Service, had paid him an unexpected and distinguished compliment in naming him to open a discussion on a theme so important.

Speaking of water-borne diseases, he dealt principally with yellow fever and cholera. With the former he had had an extended experience in the tropics, largely as a practitioner at Panama—and India, for cholera.

Dwelling on the epidemics of yellow fever seen by him, he incidentally referred to the very valuable and effective work done by Dr. Domingos Freire, a Professor of the Faculty of Medicine in the University of Rio de Janeiro, whose preventive inoculations for yellow fever were rich in promise, and already doing good work in Brazil.

Taking up the responsibility of nations in fostering and spreading disease, he said that they should be called to the bar of Nations and there held to a strict accountability. Nations, like individuals, have a responsibility, and should be held to it.

Passing to that most important of themes, quarantine, he described the ideal quarantine as that thought out and perfected by Dr. Joseph Holt, of New Orleans, a perfect system, one meeting every requirement. Dr. Holt's name as an American sanitarian was world-wide.

Following the papers there was discussion, the speakers being Dr. Austin, of the Washington Marine Hospital Service; Dr. George B. Scales, of Mobile, Ala.; Dr. Patton, of New Orleans; Dr. Kelly, of Minneapolis; Dr. Baker, of Illinois; Dr. Ruggles, of San Francisco; Dr. A. N. Bell, of Brooklyn, N. Y., and others.

Dr. Baker read a valuable paper on the death-rate in Illinois, showing, by a perfect set of diagrams, the mortality in that State. The paper presented many new features, particularly showing what an influence immigration was believed to have on disease.

Dr. Flick, of Philadelphia, spoke of Dr. Baker's paper as a magnificent object-lesson and peculiarly timely, showing the value of isolation and disinfection. After a case of diphtheria had been recognized and isolated, an immense spread was prevented—at least five-sixths. So much for modern sanitary science. Diphtheria was a cold-weather disease.

Dr. Lewis, of North Carolina, said that the people must be educated. They will not accept legislation unless they feel and know that it is for their benefit.

Dr. Garlick followed in much the same strain.

Dr. Baker, the reader of the paper, spoke of the dangers of sputa, germ-laden dust, etc. Diphtheria, he said, was found in the mucous membranes, and not in the blood.

Dr. Montizambert, of the Canadian Quarantine Station at Grôsse Isle, Province of Quebec, on the St. Lawrence River, referred to the work done at the station under his charge. He said that it was of the most thorough character. By courtesy of the Canadian Government two officers of the Marine Hospital Service were stationed at Grôsse Isle, saw every detail of the work, disinfection, etc.; that every piece of luggage belonging to an immigrant destined for the United States was tagged by an official of the Canadian Government, also tagged by an officer of the Marine Hospital Service. The appliances at Grôsse Isle were quite new and wholly equal to all demands upon them. Steam at a temperature of 100° and 150° Centigrade was used.

Dr. Austin, of the Marine Hospital Service, spoke of the very favorable reports in the Canadian Quarantine Station on the St. Lawrence, received from its officers on duty there. He stated that it was fully as good as the best in the United States.

Dr. Kelly, of Minneapolis, spoke of his having been one of a commission last year to visit Grôsse Isle and study its exact workings, detail for detail. He described it as being perfect. There they saw three hundred bales of infected rags in flames. When the commission reached Boston they found an antiquated box of some nine feet by eight, as the sole disinfecting apparatus. At that very time vessels were in the harbor of Boston, laden exclusively with baled rags from the cholera infected districts of the continent. Dr. Kelly's energetic and manly praise of the Canadian Station was received with applause.

After the discussion the following resolutions were in order:

"*Resolved*, By the Section on Hygiene, Climatology, and Demography, that the following resolutions be added to the resolutions already adopted by this Section, relating to the temporary suspension of immigration and the exaction of scrupulous cleanliness of all vessels arriving at American ports.

"*Resolved*, That it is also the opinion of this Section that the habitual and thorough disinfection of all personal effects liable to carry contagion of immigrants to the American hemisphere, and of dunnage of crews of vessels carrying these immigrants from any quarter of the globe, and the exaction of scrupulous cleanliness of all vessels arriving at American ports, should be enforced at all times as the most efficient means of greatly lessening the introduction of the seeds of the various contagious diseases, which are now, and have been in the past, almost constantly conveyed by the immigrant classes, and distributed widely among the populations of this hemisphere."

Dr. Gihon declared the work of the Section closed, and in graceful phrases in English and Spanish thanked the members for their close attendance during four days. The Section had had an average of over fifty a day, exceeding any section of the meeting. A vote of thanks to the President for the very able manner in which he had presided was seconded and carried amid applause, when the Section was declared closed.

Should Medical Professors Practise?—The question is now debated whether professors at the Medical Faculty of Paris ought to practise their profession. The *Journal des Connaissances Médicales* thinks they should not; the state looks to them to form medical men, to give them the instruction necessary to enable them to maintain the public health in the most satisfactory condition. They should inoculate the pupils who crowd round them with a love of study, and instil into them scientific principles. It is the Faculty professors who are to educate medical students to be accomplished, able medical men, fitted to foresee illnesses, to diagnose them, and combat them. In order so fulfil this mission, the professor must be a studious, scientific man. Study is, it is contended, impossible in a life occupied in other ways. A medical practising professor has no time on his hands; frequently a day's work is insufficient to visit all his patients. Practising medical men, even the most distinguished and scientific among them, can only keep themselves abreast of the progress directly bearing on medical practice; this knowledge is not sufficient to enable him to form other minds desiring to rank with his own. Bedside teaching is furnished by the clinical professors.

The "Dixie Doctor" is Dead. We are sorry, for it was lively while it lasted.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

OPENING OF THE WINTER SESSION AT THE LONDON MEDICAL SCHOOLS.

LONDON, October 5, 1893.

ON October 2d the medical schools in connection with the London hospitals commenced the winter session. At some a *conversazione*, the distribution of prizes, or a dinner was substituted for the usual introductory lecture. At others, the time-honored custom was duly observed, as the following reports will show.

At St. Mary's Hospital, Mr. Ernest Lane was the lecturer. He referred to the recent changes which had been made in the educational curriculum, and showed the advantages accruing from an extra year's study. This additional term would have to be given to clinical work and to the acquisition of knowledge upon important subjects, such as mental disorders and fevers; studies which had been partially neglected. The added curriculum could not fail to elevate the scientific standard of the medical profession, and to make a diploma more valuable. It might probably lessen the number of those embracing medicine as their calling in life; but by so doing it would mitigate some of the ills of overcrowding in their ranks, among which were excessive competition and a lessening in the value attached to professional services. The lecturer dwelt on the value of a sound knowledge of anatomy, which was the very essence of the art of surgery. It was the beacon and guiding star of the surgeon; it warned of difficulties and dangers unseen, and enabled him to avoid dangers and to rise superior to difficulties. It gave him that knowledge which constituted surgical strength, and endowed him with the manual dexterity requisite to enable him successfully to accomplish any operation.

Among those inducements which might in after-life be held out to those about to enter the medical profession to deviate from the paths of professional rectitude, he referred to the institutions known as Medical Aid Associations, and defined them as a system by which a lay committee or any single unqualified individual derived considerable profit by farming out the services of a duly qualified man, who in return for a fixed salary was required to give his services to any member of the association who needed them. The medical officers of these institutions were at the mercy of a committee composed possibly of artisans, who would not forget to remind him that he was a paid servant. He was so overworked that his health would almost inevitably give way. He must soon lose not only all his self-respect, but also all interest in his work, and he would go about his daily task of drudgery in a purely perfunctory manner. The lecturer alluded to this subject at some length as an example of one of the offences against medical ethics which many a young man might be led into committing. He concluded by advising those who were commencing their medical course of the great need of regular and methodical study.

At University College Mr. Bilton Pollard gave the inaugural address, and said that these opening speeches had a special value, especially in a centre like London, in bringing prominently before the students, at the beginning of their career, that they were members of a corporate body on which their careers would reflect distinction just as its glorious past would reflect distinction on them. The profession was very exacting and would not tolerate any serious rival, but he hoped that, so far as their studies permitted, they would not neglect any of the educational advantages with which London abounded. The metropolis, with its buildings, its museums, and art collections, was an education in itself. In pursuing their studies they must know that accuracy and thoroughness in observation were the foundations of success. If once acquired they had the root of the matter in them. The lecturer then considered some of the ways in which their studies were carried out. He defended instruction by systematic lectures; by attending these they would feel the stimulus of the lecturer's personality, and perhaps imbibe some of his enthusiasm for the subject. The lecturer impressed on those commencing hospital work the duty of making painful manipulations as short as possible, consistently with their objects. With that in view it was needful to determine clearly what they wished to investigate, and then to carry it out as systematically and rapidly as possible. It was positively wrong, as well as unscientific, to fumble about an injured or diseased part with the hope that something might turn up by doing so. It was sometimes said that doctors' feelings became blunted by familiarity with disease. For his part he believed, on the contrary, that this rather tended to show the sympathetic side of their natures. They must bring their own intelligence to bear on debatable subjects and not permit their judgment to be warped by reverence for authority. Had not those immediately preceding their own times broken away from the trammels of authority and gone straight to nature for inspiration and guidance, the wonderful progress of recent times could not have been accomplished. He advised the students to cultivate a kindly and sympathetic bearing toward poor patients, for they might rest assured that if they possessed the personal qualities which secured for them the confidence and affection of poor hospital patients, they owned also the qualities with which alone, as men of self-respect, they would strive to win the confidence and esteem of patients in the higher ranks of life. In his concluding remarks he heartily wished those who were approaching the end of their studies success in life, and trusted that they would carry away with them a high ideal of what true success should be. They were justified in feeling pride in the powers which their knowledge conferred on them, but he cautioned them against posing as knowing more than was known. The difficulty of a great profession demanded that they should be willing to face dangers, difficulties, and opposition, rather than sanction views that were wrong. It was felt by some that the members of the medical profession did not get the public recognition they ought to. The art of healing had an intrinsic nobility about it, but, after all, it was not the profession that ennobled a man, but *vice versa*.

At the School of Medicine for Women, Miss Helen Webb, M.B. London, begged all the students to take a broad view of the work before them. Not only by reading books or by passing examinations would they fit themselves for the practice of medicine. The kind of knowledge which was most useful was not given to many on easy terms. It called for much individual effort, and above all for time, in which the processes of intellectual digestion and assimilation might take place. In order to become a worthy medical practitioner each student must learn to combine a reverent care for accuracy of detail, with a wide view of the relations of things noticed.

During recent years increased importance had been given to preventive medicine. In the good old times, when fever or plague broke out, its presence became at once an accepted fact, and professional energy was employed to the cure of the cases as they occurred. It was most significant of the times, that during the present outbreak of cholera in Europe the literature of the subject had dealt almost entirely with the discovery of the sources of infection and its speedy destruction.

The lecturer at the Westminster was Dr. Hebb, who said that some of the medical schools began their session without a preliminary lecture, and he thought them wise in doing so. In his opinion the strictly medical training at present was not long enough. If three years was needed for the training of a nurse, how much longer should be required for that of a doctor. He complained of the number of medical schools, and thought that it was

ue to their being conducted on a commercial basis. If Mammon had not driven the car medical schools would ong ago have been concentrated as regards all except linical study, and in his opinion this would have been a istinct advantage. As to the dental branch of the pro-ession, of its ethics, if it had any (laughter), it was a uestion whether it would not be wise for the Royal Col-ege of Surgeons to dissociate itself from this branch en-irely. Speaking of the Royal College he thought more ttention should be given to the ability of a candidate to andle surgical appliances. In some cases he was afraid hat men had passed who had as much idea of the deli-ate handling of a surgical appliance as a house painter ad of depicting the Virgin Mary.

Dr. W. Pasteur in his introductory address at the Mid-le sex Hospital dealt with the question of medical educa-ion, more especially from the point of view of the ttitude of mind in which the students should apply them-elves to their studies. At present, he said, bad writing, ad punctuation, and other faults characterized many of he students, and of late years he had observed a greater umber of men who came to grief in writing prescrip-ions, and who had difficulty in appreciating the mean-ng of Latin terms. The standard of a preliminary xamination at present accepted as sufficient by the li-ensing bodies was too low and unworthy of a profession vhich called itself liberal, as, unless the raw material was mproved in quality, it must prove unequal to the educa-ional strain to which it had to be exposed.

At St. George's Hospital, Mr. Timothy Holmes natu ally took the subject of Hunter's life and works, as this vas the centenary of the founder of modern surgery who vas himself so long connected with the hospital. The xtreme value of Hunter's surgical works was pointed out, nd the extent to which they passed beyond any previ-usly published. But Hunter's great merit was that he reated surgery as a branch of the science of life, of every-hing which has been included in the term biology. In is philosophical works he was far in advance of his times, nd the impetus he gave to progress resulted in the con-tant advance visible in every branch of medicine. Hun-er's museum absorbed the labor of his later life and every uinea he could spare. The collection is now the most splendid monument of skilful labor ever raised by one nan, and the most magnificent instrument for the study of nature in the whole world, one of the glories of our ation and the city which possesses it. The students of his school—Hunter's own—were exhorted to follow him n his single love of truth, his simple and sublime disre-gard of worldly rewards, and his determination to base ll his opinions and practice on honest observations of nature.

PERSISTENT SINGULTUS AND LAVAGE OF STOMACH.

To the Editor of the Medical Record.

Sir: In the Medical Record of August 19, 1893, ap-pears an article by Dr. A. Ernest Gallant, of New York. entitled, "Persistent Singultus—Lavage of the Stomach." In the issue of September 30th of the same journal, is another article by Dr. P. C. Coleman, of Colorado, Tex., entitled, "Persistent Singultus Relieved by Lav-age of Stomach."

Dr. Gallant says: "In looking over the more recent literature on this subject, the best résumé of the treat-ment of which was given by Dr. F. W. Putnam, I find no mention of lavage, though it seems to me especially fitting in cases where there are evidences of gastric irri-tation."

Dr. Coleman, in his communication, refers in an in-definite way to an article he had read in some journal, where, after all other means had failed, a case was re-lieved by thoroughly washing out the stomach.

I would refer both gentlemen to an article written by the undersigned, entitled, "Incessant Hiccough Relieved by Lavage of Stomach," which appeared in the Medical Record of December 19, 1891. The case which I there reported was treated by me in April, 1888, while an in-terne in Cook County Hospital, Chicago. Dr. Cole-man's indefinite reference undoubtedly applies to my original article, or an abstract of it, which appeared in several medical journals. Dr. Gallant, in looking up the more recent literature on this subject, failed to run over the Index of the Medical Record, or he would have seen my article.

Very truly,

Everett J. Brown, M.D.

Decatur, Ill., October 13, 1893.

HIPPURIC AND BENZOIC ACIDS.

To the Editor of the Medical Record.

Sir: At the end of page 510 of the Record of October 14th, appears a paragraph from an exchange in which the following sentence occurs:

"As before mentioned it (hippuric acid) is excreted in the urine as benzoic acid." This I believe to be an error. The converse of the statement is known to be true. *Vide* Neubauer and Vogel, Seventh Edition, trans-lated by Cutler, page 198, II. A. 2. a.

Respectfully,

Howard Lilienthal, M.D.

33 East Thirty-first Street, New York.

Effects of Tobacco on Physical Development at Yale and Amherst.—Statistics on this controverted subject are rare. The following remarks are by Dr. Jay W. Seaver, of Yale, a reliable authority. They are based upon ob-servations made of a college class of one hundred and eighty-seven men during their first and final years. The growth of the men in four of the principal anthropomet-rical items, of varied character, is as follows:

	Weight. Pounds.	Height. Inches.	Chest girth. Inches.	Lung capacity. Cubic inches.
Non-users	11.87	.894	1.74	21.6
Irregular users	11.06	.788	1.43	14 45
Habitual users	10.66	.721	1.276	12.17

If this growth be expressed in the form of percentage, it will be seen that in weight the non-user increased 10.4 per cent. more than the regular user, and 6.6 per cent. more than the occasional user. In the growth of height the non-user increased 24 per cent. more than the regular user, and 14 per cent. more than the occasional user. In the growth of chest girth, the non-user has an advantage over the regular user of 26.7 per cent., and over the oc-casional user of 22 per cent., but in capacity of lungs the growth is in favor of the non-user by 77.5 per cent. when compared with the regular user, and 49.5 per cent. when compared with their regular user. It has long been rec-

ognized by the ablest medical authorities that the use of tobacco is injurious to the respiratory tract, but the extent of its influence in checking growth in this and in other directions has, I believe, been widely underestimated. Dr. Seaver's conclusions in regard to the dwarfing effect of tobacco are fully corroborated by the following statement by Professor Hitchcock, M.D., of Amherst College, more recently published: "The matter of tobacco smoking as an influence upon the physical development of Amherst students has been studied in the history of the class of '91. Of this class 75 per cent. have increased in their measurements and tests during the whole course, while 29 per cent. have remained stationary or fallen off. In separating the smokers from the non-smokers, it appears that in the item of weight the non-smokers have increased 24 per cent. more than the smokers; in height they have surpassed them 37 per cent.; and in the chest girth 42 per cent. And in the lung capacity there is a difference of 8.36 cubic inches (this is about 75 per cent.) in favor of the non-smokers, which is three per cent. of the total lung capacity of the class."

The Late Dr. Maxwell.—An alumnus of Charity Hospital writes: "Dr. E. A. Maxwell, whose death is briefly mentioned in to-day's MEDICAL RECORD, was a man who influenced a number of young hospital doctors in a salutary way, for which, and his unassuming kindness and ever ready advice and help, he will always be gratefully remembered by them. During the year and a half the writer of these lines served in the wards of Charity Hospital, he, as well as others of the staff, seniors and juniors, always found in Dr. E. A. Maxwell a full and ready man concerning the cases that were transferred to the dead house. His advice and instruction were always given in a manner that left nothing to be desired in so far as patient and painstaking kindness could demand. His kindnesses were of a nature that concerned not only present needs and curiosity, but had necessarily an important influence on the future interests of the young doctors; all of which, now looking back over nearly fifteen years of practical work, comes back to us, and makes us feel what a good fellow he was, and how much we lost sight of the superior man in the student who was teaching us. This unselfish interest did not end with one's departure from hospital life. However casual the meeting, one was made to feel that this man had not changed toward one. Not only his experience and learning were shared, but his time also, and now, all that we can do is to be sorry that we shall not be able to repay him the good services he unstintedly gave us."

New Remedies in Skin Diseases.—The *Medical Bulletin*, September, 1893, contains Dr. John V. Shoemaker's "Remarks on some New Remedies in the Treatment of Diseases of the Skin." As regards the local remedies lately introduced, most of them are efficacious by virtue of their antiseptic properties. The success of iodoform in skin affections of an inflammatory nature is well known. On account of its diffusive and offensive odor, aristol and europhen are welcome substitutes. Europhen contains 27.6 per cent. of iodine, is light brown in color, has a faint but not unpleasant odor, is insoluble in water or glycerine, but dissolves in alcohol, ether, chloroform, and fixed oils. It is easily decomposed by light and heat, and should be kept in a dark place that is dry and cool. Europhen is devoid of toxic properties, adheres firmly to surfaces with which it may be placed in contact, and may be employed as a powder or an ointment. It has an excellent influence upon chronic ulcers, superficial epithelioma, sycosis, chronic eczema, etc. A mixture of equal parts of europhen and aristol is an admirable dressing for fissured eczema, psoriasis, and syphilitic ulcers. In certain cases, this mixture is more efficient than either of the substances used alone. Losophan contains eighty per cent. of iodine. It is an irritant substance, adapted to chronic affections, and must be closely watched. Where there is thickening of integument and itching, losophan is of great service, as in chronic eczema. In prurigo, urticaria, paræsthesia, etc., it is very useful; and in the later periods of sycosis, in chronic acne, in the second stage of rosacea, and in parasitic conditions.

Thilanin is a combination of sulphur with lanolin, and mixes with water and oily fluids. It is available in many forms of eczema, in sycosis when inflammation is severe, and in herpes. Thiosinamin has been lately brought forward as a constitutional remedy, especially in lupus and other local forms of tuberculosis. It has a softening influence upon scars, thus removing the effects of contraction and pressure. Thiol is a sulphur compound, introduced as a pleasant substitute for ichthyol. It is admirable for raw surfaces, in herpes zoster, and dermatitis herpetiformis. Thio, resorcin, and thiophen are compounds containing sulphur. Thiophen di-iodide is employed for the same purposes as iodoform. Alumnol is a new remedy that is antiseptic, astringent, and in concentrated form, a cauterant. It may be used in aqueous solution, as an ointment, or a plaster, and is suitable for ulcers, bed-sores, chancre, herpes, erosions, abscess cavities, etc. Tumenol is obtained from the fusion of bitumen and oleum. It has been employed with success in acute eczema with weeping, in burns of the first and second degree, and in superficial and deep ulcerations. Compound stearates are combinations of stearic acid, obtained from suet, with copper, manganese, mercury, and zinc, in the form of powders. These powders may be made up into ointments. The stearate of zinc may be used as a dusting powder in intertrigo, hyperidrosis, and acute vesicular eczema. It is also useful as a vehicle for many other drugs. Piperazin, used in gout and other manifestations of the uric acid diathesis, when given internally mitigates paræsthesia that is dependent upon hepatic incompetency. Thymol possesses antiseptic virtues, and is of value in acne, alopecia circumscripta, eczema, psoriasis, and ringworm. Trichloracetic acid is applied to warts, vascular nævi, pigment patches, and indolent ulcers.

Transplantation of Eyelashes.—It sometimes happens in association with a punctured wound of the eye that an eyelash is cut off or torn from its attachment and transplanted bodily into the anterior chamber of the eye. This of course is a very untoward occurrence, because the intruding hair not infrequently sets up severe inflammation, and, if left long enough, it may set up destructive imflammation. Apart, however, from this contingency, if the root-sheath be carried in with the eyelash this may, and often does, contract adhesions with the iris or cornea and form a cyst having for contents epithelial cells derived from those of the sheath. In one instance, mentioned by Mr. Henry Power at a recent meeting of the Ophthalmological Society, the last took root on the iris and went on growing until it formed coil upon coil of hair within the anterior chamber. The nature of this curious foreign body was not very apparent, but when it was identified it was removed with a successful result.—*Medical Times.*

For Bronchial Affections.—A useful combination in the catarrhal affections of influenza, in cases of ordinary bronchitis, and in cases of broncho-pneumonia due to exposure, especially when there is an associated pleuritis, is the following:

Phenol salicylate, or cinchonidine salicylate	from 3 to 5 grains.
Terpin hydrate	" 3 to 5 grains.
Codeine sulphate	" ½ to ¼ grain.

Mix. Dispense in capsule.
Dose: One capsule with water every two to four hours.

This, or a similar prescription, is likewise beneficial in the "colds," bronchitic, pneumonitic, and pleuritic, that often retard recovery or cause "set-backs" in cases of pulmonary tuberculosis improving, or apparently well-under hygienic and other appropriate treatment. In simple pleurisies and in rheumatic pleurisies the terpin hydrate may be omitted.—*Dr. S. Solis-Cohen.*

PRACTICAL POINTS IN THE TREATMENT OF HIP DISEASE.[1]

BY A. B. JUDSON, M.D.,

ORTHOPEDIC SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

HIP disease may be called a semi-malignant affection because of its duration and its destructive quality. But it is almost never fatal. In every large community there are many healthy and active adults who are scarred and deformed by hip disease, without ever having had adequate treatment. In all stages of the disease it may be predicted, excepting in patients who are exceptionally unfortunate in their surroundings, that the time will come when the forces of nature will rally and repair take the place of disintegration.

In approaching the subject of treatment it is necessary to bear in mind that the destructiveness and inveteracy of this disease are largely the result of mechanical environment. Its full counterpart in the upper extremity is not found, evidently because in the upper extremity the focus ignited in the cancellous tissue is, as a rule, resolved at an early stage by reason of the exemption of the upper extremities from the labors and hardships attending locomotion. We cannot do better, therefore, than to nullify pernicious mechanical environment. By so doing we directly banish trauma from the part affected, and indirectly fortify the general health, and in both ways invite the advent of a "natural cure."

The three cases which are to be cited illustrate the good effect of mechanical treatment, in the most unpromising cases.

CASE I.—A boy, six years of age, presented an enormous abscess, and all the usual symptoms of the last stage of the disease, which had continued in the right hip for nineteen months. Exsection of the joint had been urged by a surgical attendant. The abscess opened spontaneously on the first day the patient was seen, and before treatment could be begun. The child's general condition was bad. The limb was greatly adducted and flexed, and the slightest disturbance of the joint caused severe pain. Mechanical treatment was begun the sixth day after the patient was first examined. Pain was relieved at once. He was enabled to be out of bed without delay, and out of the house nearly every day, throughout the entire course of treatment, which lasted two and a half years. The affected joint received the benefit of fixation, or a reasonable degree of immobilization, and was thoroughly protected from the traumatic incidents of locomotion. The adduction of the limb gradually and painlessly disappeared as the boy made use of the limb, protected by the splint, in walking, and flexion was reduced till the limb was in a position favorable for locomotion. Wearing the splint the patient pursued the ordinary occupations of a boy of his age, while the reparative process supplanted the ravages of disease. The abscess already referred to was followed at irregular intervals by other purulent collections which were incised or allowed to open spontaneously. At one time there were nine sinuses about the joint, all derived from diseased bone. Five of these extended in a line down the outer side of the thigh from the trochanter to near the middle of the shaft of the femur, as seen in Fig. 1. The position of these sinuses, from one of which a sequestrum was extruded, and the attachment of the resulting cicatrices to the bone showed that the shaft of the femur was, to a great extent, involved in the destructive process. The patient's condition

FIG. 1.

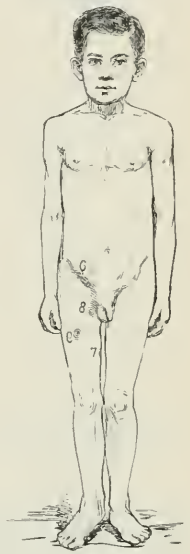

FIG. 2.

six months after the cessation of treatment is shown in Figs. 1 and 2. The limb is in good position, neither abducted nor adducted, and flexed at a slight angle, enough to allow him to sit comfortably, and yet not enough to interfere with graceful locomotion. He walks with firmness, runs fast, and never uses a cane. There is practically no "apparent" shortening, that is, the shortening due to adduction and flexion. The "real" shortening is one inch, due partly to changes in the femoral head and neck, but more to the fact that the skeleton of the affected limb is smaller than that of the well limb. This difference is seen in the difference between the outlines of the feet, as shown in Fig. 3, and is also due partly to the fact that the growth of the affected limb has been retarded by disease, while the development of the well limb has been forced by over-exertion for so long a period. The position of the sinuses is shown in the figures. The scars are depressed and attached to the deep fasciæ and bone. They are numbered in the order in which the sinuses appeared. Figs. 1, 2, 4, 5, 7, and 8 are copied from photographs.

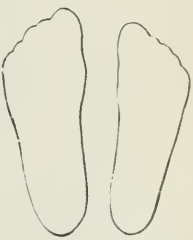

FIG. 3.

CASE II.—A girl, three years of age, had a family history in which the mother, the maternal grandmother, and

[1] Presented at the Pan-American Medical Congress, held at Washington, September, 1893.

three paternal uncles and aunts had died of pulmonary tuberculosis. (The family histories in Cases I. and III. were remarkably free from similar incidents.) The disease had been present in the right hip a year and more. Treatment had been by the immovable plaster-of-Paris dressing, the wheel crutch, and by portative apparatus in which there was provision for motion at the knee, but not for traction. When first seen, the child presented the marked adduction and flexion characteristic of an advanced stage. She had suffered for several weeks the severe pain which forebodes an abscess, and is due probably to the retention of pus in the cancellous tissue of the

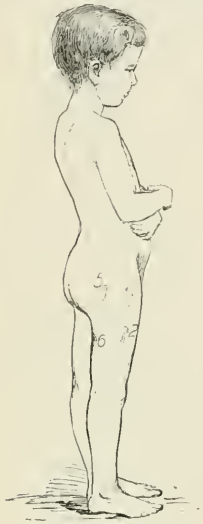

FIG. 4.

FIG. 5.

bone. Soon after the application of mechanical treatment the position of the limb improved, adduction giving place to abduction, and flexion being materially reduced. The pain ceased, as the result, perhaps, of the escape of pus from the hard shell enclosing the cancellous tissue. Five months after treatment began the pus was released from the soft parts by incision, and in the following eighteen months five other sinuses were established spontaneously or by incision. Their location and order are indicated in Figs 4 and 5, which show the child's condition eight months after the cessation of treatment. The scars are attached to periosteum and deep fasciæ. Her health is perfect and she walks and runs without assistance of any kind. The position of the femur is favorable both for walking and sitting, there being no abduction or adduction, and but a moderate degree of flexion. The real shortening is only one-fourth of an inch. The outlines of her feet are shown in Fig. 6. When she walks with care it is difficult to perceive any defect, although the motion in the joint itself is so slight as to be of very little use in locomotion, advantage being unconsciously taken of the flexibility of the lumbar region of the spine and of the unimpaired mobility of the sound hip-joint. Fast walking and running develop a limp, but not enough to exclude her from the ordinary pastimes of youth.

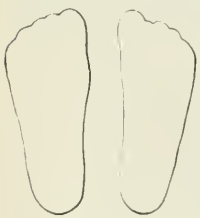

FIG. 6

CASE III.—A boy, seven years of age, had suffered from disease of the right hip for four years. His father was a dealer in surgical instruments and the boy had worn elaborate appliances, the chief defect of which had been in the slight construction of the frame of the portative splints which had failed to make sufficient traction or to relieve the affected joint from the weight of the body in standing and walking. The usual signs of an advanced stage were present, and an abscess was pointing when

FIG. 7.

FIG. 8.

treatment commenced. Improvement in the position of the limb was soon seen. In course of time four sinuses were established, either spontaneously or by incision, as seemed to be necessary. The case progressed favorably and the duration of treatment was four and a half years—longer than was necessary through excess of caution and anxiety on the part of the father. Figs. 7 and 8 show the boy's condition eighteen months after all treatment was discontinued. Scars 2 and 4 are attached to the underlying bone. He takes long walks without fatigue, is a good skater, and walks and runs with great speed, although motion in the joint is practically wanting. He never uses a cane. When walking carefully there is no defect in his gait. There is one-half inch of real shortening. The outlines of his feet are shown in Fig. 9. The position of the limb is good, there being a moderate degree of flexion, enough to facilitate sitting, but not enough to interfere with graceful locomotion. There is neither abduction nor adduction.

FIG. 9.

Since these cases were reported the patients have retained their health and activity, but two of them have lost some of the symmetry above noted. The femur became flexed and adducted, not enough to compromise ability in locomotion, but yet enough to give a defect to the gait. This is evidently the result of a failure to re-

tain the prescribed natural rhythm of walking. The third patient, becoming a medical student, understood and appreciated the importance of rhythmical locomotion, and retains the symmetry recorded.

These cases are not presented to illustrate the achievements of mechanical treatment in early and promising cases, but to show what should be the result in cases of the worst kind taken in advanced stages, provided the assistance of intelligent and thrifty parents is assured. In favorable circumstances and with treatment begun at the earliest sign of a focus, the result should be, and sometimes is, such as to make it difficult by careful examination and measurement to discover any asymmetry or trace of disability.

The same general rules or principles of treatment hold good in the earliest stage and in the most desperate and advanced stages. Treatment should make sure of four things: 1. Preservation of the general health throughout the treatment; 2, the arrest of motion in the joint in the acute stage; 3, the removal of the weight of the body from the joint in all stages; and 4, provision for final symmetry and locomotor ability.

The first consideration is the general health of the patient. On this we rely, in the absence of specific medication and established operative procedures, for the natural return of the affected part from progressive destruction to progressive repair. Can a patient thus beset be better off than when equipped so that he can rise from his bed after a painless sleep and pass the day up and dressed, and with his schoolmates and play-fellows, his appetite and respiration stimulated by happy hours passed in the fresh air and sunshine? With suitable mechanical equipment the patient should not, and will not if left to himself, pass an hour of his waking time in the invalid's bed.

Second, the arrest of motion in the joint may be amply secured by the traction exerted by the hip-splint in those stages in which it is required by the painful condition of the joint and the apprehension which the very thought of articular disturbance excites in the mind of the patient. Absolute immobilization is out of the question from the mechanism of the hip-joint, but fixation, or a reasonable degree of immobilization, is easily produced, and conveniently maintained.

Third, the patient equipped with the hip-splint, when standing and walking, is prevented from putting his weight on the joint. The heel cannot reach the ground. The patient sits on the perineal strap of the apparatus, which is essentially a crutch-head applied to the ischiatic instead of the axillary region. With this arrangement he wears a high sole on the well foot to make up for the factitious length which is given by the splint to the affected side. It is not entirely fanciful to say that the patient is sitting while walking, because he alternately stands on the well foot and sits on the perineal strap. An adult patient tells me that when tired he rests, while still erect, by leaning against some support and sitting on the hip-splint. It was thought at one time that it was impossible for a patient to go for any time touching the ground with only one foot. With the hip-splint, however, children run about for years, putting their weight on the well limb alone, the affected leg being thus converted into a pendent member, like the arm.

Fourth, the patient while wearing the hip-splint may be induced by instruction and drill to give up the "false time" of his footsteps, which is the chief cause of the deformity and limp of hip disease, and to return to the natural rhythm of human locomotion, in which equal time is given to the two feet. The result of walking habitually in this way is at once the abolition of a great deal of the appearance of lameness and in time the correction of deformity, because the adducted limb will pass, without conscious effort on the part of the patient, from adduction to abduction (with, at the same time, and for the same reason, a decrease in flexion) in order to place itself in that position in which it can best do its half of the work of progression, thrown upon it by the adoption, or rather the resumption, of natural rhythm or "correct time" in walking.

A few words are in place describing the apparatus and its application. Its frame is made of steel. In use it does not require to be bent, as so many pieces of orthopedic apparatus do, therefore it may be well, but not too sharply, tempered. It consists of upright and pelvic band, as shown in Fig. 10. The upright, shown in Fig. 11, extends from the ground to a point about midway

Fig. 10.

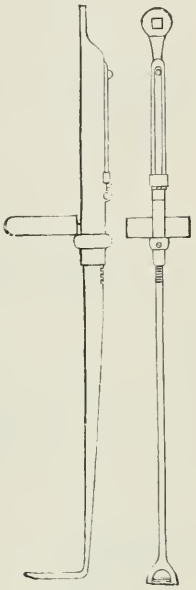

Fig. 11.

between the iliac crest and the trochanter. It is flat, with its width laterally disposed, and its thickness anteroposteriorly, an arrangement by which the strength of the metal is in the direction of the strain when the patient's weight is borne by the instrument. It is composed of a bar and a box, the former being propelled in the latter by a rack and pinion, and held at the point of election by suitable mechanism. The box is attached above to

Fig. 12.

the pelvic band, and the bar ends below in the foot-piece, which is shod with leather and carries two leather straps. A high sole for the well side is conveniently carved from a block of light wood and fastened to the sole of the shoe in the manner shown in Fig. 12. Properly shaped and stained it is quite as presentable as the more expensive cork sole. A knee-piece is adjustable on the upright, and, being of soft steel, is easily adapted to the size of

the lower part of the thigh. If the patient is tall and requires a longer upright, this piece is carried on the bar, instead of, as in Figs. 10 and 11, on the box, thus doing away with the necessity of increasing the length of the latter with the increased length of the upright. A piece of webbing is buckled around the upright and the limb at the lower part of the thigh, and a leather strap around the upright and the lower part of the leg. The pelvic band, shown in Figs. 10 and 13, is a nearly semicircular piece of bar steel, covered with leather, or better, with hard rubber, the angle of its attachment to the upright being adjustable and firmly fixed by a bolt and nut. It carries the perineal strap of webbing, padded with blanketing and covered with canton flannel. A strip of adhesive plaster from one and one quarter to three inches wide, and ending below in a buckle, extends on each side of the limb from the middle of the thigh to the lower part of the leg. The plaster is protected by a legging made of twilled muslin provided with eyelets for lacing.

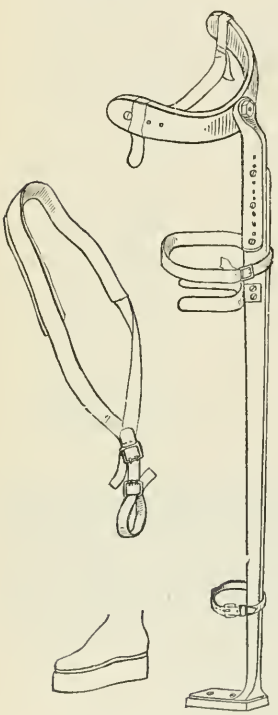

Fig. 13.

To apply traction to the limb the leather straps attached to the foot-piece are buckled to the adhesive plaster strips attached to the limb, the perineal strap is buttoned over the ends of the pelvic band, and the rack is propelled in the direction of the foot by the pinion or key. In practice, if the patient is more than a mere child, he uses the key at will, and may be depended on, if the joint is in a painful or tender condition, to keep up steady traction as long as there is any indication for its use. It was thought at first that traction thus applied relieved pressure on painful articular surfaces, but there is excellent reason to believe that its good effect is due to the fact that it assists the patient in his conscious and unconscious (voluntary and reflex) efforts to keep the joint from motion, in other words, that it produces fixation, or a reasonable degree of immobilization. The knee-piece is useful in the same way. Worn at the lower part of the shaft of the femur, it hinders motion at the knee, and, *pari passu*, at the hip. There is probably no more distressing sight than that of a patient in the acute stage of hip disease, and no resort of surgery is more simple in *modus operandi* and more certain to give relief than the application of traction in this way.

In this stage the apparatus should be applied although abscesses and great deformity are present, as in the exceptionally difficult cases related above. The end of the pelvic band may extend obliquely over the abdomen on account of the adduction of the limb. It may even be necessary at the beginning to attach the perineal strap by buckles instead of loops, to gain for it a suitable length, and in some cases to apply it to the perineum on the sound side. But with care and gentleness the apparatus can be arranged in some way so that a slight and increasing amount of traction is effected. Immediate relief from pain is followed soon by reduction of the deformity, so that in a few days the restored symmetry of the patient's figure will enable him to wear the splint properly adjusted and comfortably. The pelvic band may then be brought down to its proper place on a level midway between the anterior superior spine of the ilium and the pubic bone. It may thereafter be kept at that level if the perineal strap is of the right length and suspended by loops instead of buckles. A bed-ridden patient treated in this way soon recovers strength from the return of sound sleep, and before long seeks to leave his bed and try walking without crutch support except that afforded by the perineal strap. A high sole is attached to the shoe of the well foot, and a shoulder-strap, shown in Fig. 13, transfers the weight of the splint to the opposite shoulder, and he is instructed in the necessity of acquiring, as soon as it can be done by daily effort, the habit of moving his feet in correct time. He then ceases to be seen at his home or in the hospital ward, and becomes an "office patient" or an "out-patient."

The splint as thus far described is to be worn day and night. It makes traction on the limb and protects the joint from the traumatisms of walking. The latter is necessary in all stages of the disease, but there are long periods when traction is not necessary, when all that the patient requires is a perineal or ischiatic support to keep the affected limb from reaching the ground. The adhesive plasters and the rack and pinion and other machinery for maintaining traction may therefore be dispensed with during a large part of the treatment. The simple upright, shown in Fig. 13, may then be used instead of the upright shown in Figs. 10 and 11. Alteration in the length of this upright and adjustment of the knee-piece are provided for in a simple manner. The adhesive plasters are removed from the limb and the leather straps from the foot-piece, but in all other respects the apparatus is applied and worn as if it were a traction splint. Thus simplified, however, it is essentially an ischiatic crutch, and, like any other crutch, it is to be laid aside at night.

In closing it may be said that the apparatus, thus arranged as a crutch, may be useful in many other affections besides hip disease. If its simplicity and convenience were generally recognized it might facilitate the treatment of any disease or injury of the lower extremity in which it is desirable to let the patient take exercise without using the affected limb.

Treatment of Herpes Zoster.—Brocq recommends the following ointment:

R. Boric acid	1 part.
Oxide of zinc,	
Starch	āā 2 parts.
Vaseline	6 parts.
Lanoline	9 parts.

The vesicles are carefully opened by means of a needle sterilized in the flame of an alcohol lamp, and are then washed with a boric acid solution containing a small proportion of alcohol. After this they are covered evenly with the above paste, and powdered with starch, and over all is placed a thick layer of wadding. If the pain is very severe, a little chlorohydrate of morphine or cocaine is incorporated with the ointment.

The Microbes of Bank-notes.—Two bacteriologists of Havana, Acosta and Grande-Rossi, have been studying the microbes of bank-notes. They have proved that the weight of these notes increases in the course of circulation by reason of foreign matter. Then microbes appear, their number exceeding nineteen thousand in one instance. The presence of a septic bacillus that rapidly kills animals inoculated with it, the specific microbe of the bank-note, has also been discovered. Besides this, for which the name bacillus septicus aureus has been suggested, there were eight distinct pathogenic species found upon the Havanese notes, among which were the bacilli of tuberculosis and diphtheria, and the streptococcus of diphtheria.

QUINSY AND ITS TREATMENT BY EARLY INCISION.[1]

By JOHN WINTERS BRANNAN, M.D.,

NEW YORK.

PHYSICIAN TO BELLEVUE HOSPITAL; PATHOLOGIST TO ST. FRANCIS HOSPITAL, ETC.

THE subject of this paper may perhaps seem better suited to a society of specialists rather than to an organization like this made up for the most part of general practitioners. And yet there is probably no one present who has not at some time been obliged to act promptly and without the aid of a surgeon in a severe case of phlegmon of the fauces. The writer, at all events, has been placed in such a situation more than once, and a recent experience of the kind has led him to make a somewhat extended study of the subject.

Until within recent years, the affection we are about to consider was included under the head of tonsillitis. Fletcher Ingalls,[2] in the latest edition of his work, and practically all systemic writers on medicine, still fail to separate the disease from inflammatory processes located in the tonsil, though Ingalls admits that the abscess forms outside the gland itself in at least four-fifths of the cases. Bosworth,[3] however, and laryngologists generally, now usually employ the term of peritonsillar abscess as more correctly describing the condition in the throat. I have retained the old name, quinsy, as leaving the ground open for discussion as to the exact seat of the pus in the most common form of the affection.

Quinsy is not a very rare disease and in private practice probably the majority of cases are seen in the first instance by the family physician rather than by the specialist in throat diseases, though the aid of the latter may be required later. A severe case of quinsy is never a light matter to the patient. Though of almost uniformly favorable prognosis there is, perhaps, no affection which for a time causes such acute discomfort to the individual affected with it. Most cases result in the formation of pus, and until this is evacuated, either spontaneously or by incision, the patient's misery is extreme. Many practitioners and even some surgeons, among them Verneuil,[4] have expressed themselves as opposed to instrumental interference. But the general practice at the present day is to give vent to the pus as soon as its situation can be determined. The instantaneous relief given by an opening in the right place is most striking. On the other hand, scarification of the tonsils, as is sometimes recommended, does no good, and usually aggravates the patient's condition. As an illustration, I will narrate briefly a case seen by me last spring. The patient was a servant in a family in my neighborhood and was under the care of a physician living in a distant part of the city. I was roused in the night and asked to see her at once, her husband telling me that she was in danger of suffocation. I found the patient in great distress, presenting the picture with which you are all familiar. I learned that she had been ill for some three days and that both tonsils had been repeatedly lanced on the previous day with the result of simply adding to her discomfort. With some difficulty I succeeded in opening the patient's mouth sufficiently to get a fair view of the interior. Both tonsils were enlarged and red and showed also a white follicular deposit. The uvula was very œdematous, and the soft palate on the left side was enormously swollen and bulging and livid red in color. To the finger it felt elastic, with a doubtful sense of fluctuation. After applying a solution of cocaine I made a free incision at a point about midway between the base of the uvula and the last upper molar tooth on the left side. There was at once a gush of pus, with immediate relief to the patient, and in two or three days she was well.

I afterward discussed the case with the attending physician. He frankly admitted the good results of the incision through the soft palate, but believed that the operation was attended with the danger of wounding some of the large vessels in the neighborhood. As he is a man of large experience and good judgment, and such danger had never occurred to me, I thought the subject would repay investigation. I have asked the opinions of a number of medical men, including both laryngologists and general practitioners, and their answers have been pretty much to the same effect. The specialists have all said that the abscess is usually situated outside the tonsil and lies in the anterior or posterior pillar of the palate or in the palate itself. They believed in giving free vent to the pus wherever found, and were convinced that the operation was attended with no danger if properly performed. The general practitioners were naturally rather less positive in their opinions. They admitted that it was good practice to let out the pus when you were sure where it was, but that it was not always easy to find.

On consulting the literature of the subject I found the most recent authorities agreed as to the location of the suppurative process and the proper point for incision. Chiari,[1] Bosworth,[2] and Shech [3] state that the inflammation begins in the connective tissue about the tonsil and usually extends into the soft palate. They advise that the opening should be made at the point I have already indicated, namely, midway between the uvula and the upper alveolar process of the affected side.

Of 32 cases seen by Chiari, in which pus formed and was evacuated spontaneously or by incision, the point of opening was through the soft palate in 18 cases, through the tonsil in 8, through the posterior faucial pillar in 2, through the anterior pillar in 1, near the ramus of the lower jaw in 2, and in 1 case the place of discharge was not found.

Bosworth's statistics show that of 130 cases of quinsy, the process was located in the soft palate in 115, in the posterior pillar of the fauces in 11, in 2 cases the abscess developed beneath the tonsil and discharged upon its surface through one of its crypts, and in 2 cases the posterior wall of the pharynx was involved.

In the few cases of which I have notes, seven in number, all seen in private practice during the past three years, the soft palate was uniformly the chief seat of suppuration.

Rice,[4] in a careful study published some two years ago, came to the same conclusions as the above, except that he usually prefers to puncture through the anterior pillar of the fauces.

All of these writers, with the exception of Bosworth, regard the operation as perfectly safe when performed with a good illumination and with care. Bosworth expresses himself as follows: "In making this incision one always bears in mind the proximity of the large blood-vessels of the neck, and the possible danger of wounding them. I have incised the phlegmon in a very large number of cases of quinsy, and in no case have I done it without a certain degree of nervousness on this account; and yet it seems to me that if one recognizes the true pathological condition, and has localized the suppurating point, one ought to feel confidence in the manipulation. When, however, we consider that so great a surgeon as Chassaignac, in operating upon a faucial phlegmon, wounded what was probably the internal carotid artery, necessitating the ligation of the common carotid, it would seem to be an accident that might happen to anyone. Similar instances are reported by Duke and Murphy."

Bosworth's caution would appear to be well founded when we read what the standard anatomists have to say on this point. According to Holden,[5] "The tonsil lies close to the inner side of the internal carotid artery. It

is only separated from this vessel by the superior constrictor and the aponeurosis of the pharynx."

Gray [1] also warns us that "the relation of the internal carotid with the tonsil should be especially remembered, as instances have occurred in which the artery has been wounded during the operation of scarifying the tonsil, and fatal hemorrhage has supervened." Quain [2] does not treat of the surgical relations of the artery, but simply states that "it rests on the rectus anticus major muscle and has the pharynx and tonsil on its inner side." Cruveilhier [3] says, "the relation of the artery with the external surface of the pharynx explains how this vessel may be wounded from the interior of that cavity. Sometimes one of its curves approaches the region of the tonsil; and this may, perhaps, have been the case when the artery has been wounded by an instrument directed transversely outward and carried into the tonsil, either to open an abscess or to excise the gland." Leidy,[4] expresses himself in terms almost identical with those of Quain. Tillaux [5] also asserts that "the tonsil is only separated from the internal carotid by the thickness of the pharyngeal wall," and that "the relations of the artery with the gland should be present to the mind of the surgeon each time that he opens an abscess of the lateral wall of the pharynx."

The views I have just quoted of the relations of the internal carotid artery, are the same as those generally taught by lecturers on anatomy at the present day.

The special studies of the laryngologists should, however, lead us to a modification of these views. Delavan [6] was, I believe, the first in this country to question the accuracy of the observations of the older anatomists. As long ago as 1880, he wrote that "the relations of the tonsil to the internal carotid artery are not so intimate as commonly is supposed, for, between the lateral wall of the pharynx, the internal pterygoid, and the upper cervical vertebræ, there is a space filled with cellular tissue, the 'pharyngo-maxillary interspace,' in the posterior part of which are located the large vessels and nerves, and which lies almost directly backward from the pharyngo-palatine arch. The tonsil corresponds to the anterior part of this interspace, so that both carotids are behind it, the internal carotid 1.5 centimetre, the external carotid two centimetres distant from its lateral periphery. Hence, the danger of direct injury to the internal carotid in excision of the tonsil is infinitely small."

Zuckerkandl [7] also has recently made a most careful study of this region. The drawings made from his dissections show that the pharyngo-maxillary space is divided by the stylo-glossus and the stylo-pharyngeus muscles into an anterior and a posterior chamber. The anterior chamber is contiguous to the tonsil; the posterior chamber contains in its hindermost part the internal carotid artery, the jugular vein, and the vagus nerve. The two chambers are filled with fat and loose cellular tissue and communicate with each other by a very small opening, which gives passage to the inferior palatine artery.

It is probable, as suggested by Chiari, that the anterior chamber of the pharyngo-maxillary space is alone involved in the great majority of cases of quinsy. The firm wall formed by the muscles described by Zuckerkandl prevents the passage of the pus into the posterior chamber, whereas the tissues of the soft palate yield readily to the advancing inflammation. In rare instances, however, the pus does force its way backward between the stylo-glossus and stylo pharyngeus muscles, with the results to be indicated later.

The soft palate, through which the evacuating incision is usually made, is distant in adults at least three centimetres from the vertebræ against which lies the internal carotid artery. Even in the child the space is considerable, larger relatively than in the adult. I have lately had the opportunity of dissecting a number of new-born infants, and in no case did the distance between the palatal border and the anterior surface of the spinal column measure less than 1.5 centimetre. These measurements apply to the normal pharynx. In the condition we are considering, the soft palate is pushed so far forward by the purulent collection that its anterior margin must be nearly double its normal distance from the vertebræ. An incision of even two centimetres in depth could not, therefore, possibly reach the internal carotid artery. The ascending pharyngeal artery, which has been thought to be wounded in some cases, also lies on the vertebræ, and is therefore equally out of reach of the knife.

Having apparently shown the impossibility of wounding the carotid artery, what are we to say of the cases alluded to by Bosworth, Gray, and Cruveilhier. I have analyzed every case cited by these writers and have failed to find one in which the autopsy showed this artery to have been wounded by the knife. In those cases in which no autopsy is recorded, it is evident from the clinical history that the bleeding vessel was diseased before the surgeon intervened. Let us first take the cases referred to by Bosworth, those of Chassaignac, Duke, and Murphy.

Chassaignac [1] reported his case to the Surgical Society of Paris. It was that of a man with a fluctuating tumor at the base of the lower jaw on the left side, projecting into the pharynx. There was no pulsation and Chassaignac made the diagnosis of retro-pharyngeal abscess. An incision was made with no result. A second incision nearer to the median line was followed by a jet of arterial blood. The hemorrhage continued in spite of local pressure and was only checked by ligature of the common carotid. It was a question whether the tumor was an abscess involving the vessels or was an anomaly of the internal carotid. It has apparently escaped the notice of all commentators on this case of Chassaignac, that he reported at another meeting of the same society, some two weeks later, that the tumor still persisted, leaving its nature still more in doubt, whether a phlegmon, an aneurism, or a neoplasm. It is possible, from the location of the incision, that the case was one of abnormally large pharyngeal artery, such as those recently described by Farlow.[2]

Duke's [3] case was that of a man who had received a blow on the side of the head. During the following year he complained of headaches and sometimes of a rushing sound in the head. He then had symptoms of a sore throat. Examination showed swelling and inflammation of the right tonsil and fauces, accompanied with difficulty of swallowing and fever. On digital exploration with the view of incising the supposed abscess, strong pulsation was felt. An aneurismal bruit was also heard behind the angle of the jaw. Duke refused to puncture the swelling, but an incision by a less cautious colleague was followed by free arterial hemorrhage. Ligature of the carotid became necessary and the patient apparently recovered. Five weeks later, in consequence of a journey and the use of spirits, secondary hemorrhage occurred and death resulted. There was no autopsy. The case was supposed by Duke to be one of false aneurism, consequent upon the blow to the head. The editor of the *Lancet*, however, in commenting upon the case, thought it rather a case of abscess caused by the blow, with subsequent communication with the carotid by erosion.

The case narrated by Murphy [4] did not occur in his own practice, but was simply known to him by hearsay, he having been in the neighborhood at the time. The story was as follows: The celebrated Irish surgeon, Cu-

sack, of Dublin, was shooting with friends on the bogs of Tipperary. A woman suffering from tonsillar abscess was brought to him. He plunged his lancet into the tonsil and she died of hemorrhage in five minutes. There was no autopsy, as the surgeon was obliged to run for his life. It was thought at the time (fifty years ago) that the internal carotid artery had been wounded. In the light of our present knowledge it is more probable that the hemorrhage was due to previous ulceration of the carotid or was from the tonsillar artery, as in the following case of Stanley.

Stanley's[1] case is very instructive, the clinical history being supplemented by an autopsy. The patient, a man, twenty-four years of age, entered St. Bartholomew's Hospital, bleeding slightly from the left tonsil. The tonsil was the seat of an abscess which had been punctured by a surgeon in attendance outside the hospital. The hemorrhage recurred from time to time during the next three days, then became profuse, necessitating the ligature of the common carotid artery. The patient did well for eight weeks, then died suddenly from acute softening of the brain. It had been supposed that the internal carotid artery had been wounded, but the autopsy revealed a wound of the tonsillar artery and not of the carotid. Had a correct diagnosis of the condition been made in this case, the hemorrhage might have been checked by pressure over the tonsil, or, at all events, by ligature of the external carotid instead of the much more serious operation that was resorted to.

The above cases comprise all those I have been able to find recorded in which excessive hemorrhage has followed incision of an abscess in or about the tonsil. And in no one of them was it proved that the internal carotid artery was wounded by the knife of the surgeon. But there is another danger to be considered in operating on a phlegmon of the fauces, which has been alluded to in the histories of the cases of Duke and Murphy. A number of instances have been reported of fatal hemorrhage in quinsy, in which autopsy showed an eroded or ruptured artery, generally the internal carotid. Both Bosworth[2] and Chiari[3] mention the occurrence of this accident, but neither one connects it with the operative interference of the attending surgeon. And yet it is the evacuation of the abscess into the pharynx, whether spontaneously or by incision, that causes the rupture of the weakened walls of the artery, or allows free escape of the blood already outside of the vessel, but pent up in the pharyngo-maxillary space.

It has long been held by surgeons that the walls of arteries are proof against the destructive action of pus, so that even prolonged contact with it does not cause perforation of the vessel, unless there be local mechanical irritation, as from a drainage-tube or a bony sequestrum. When Liston[4] reported his celebrated case of spontaneous perforation of the common carotid artery fifty years ago, the London Medical and Surgical Society refused to incorporate it in their Transactions, and he was obliged to publish it at his own expense. Since that time, however, other cases, equally striking, have been recorded, and it can no longer be doubted that spontaneous ulceration of arteries does occur simply from the corrosive action of pus.

Monod,[5] in an interesting study of this question, made a collection of eighty-eight cases of erosion of arteries, including six in which the carotid was the vessel involved as a complication of quinsy. Vergely[6] adds ten cases of perforation of the carotid to Monod's list, one of the cases being from his own practice. Four of Vergely's cases are not strictly instances of acute suppuration in the tonsillar region, hence I have excluded them. I have, however, found eight additional cases[7] in the literature of the subject, making a total of twenty in all. All of these were cases of acute faucial phlegmon. The only doubtful one in the series is that of Duke, in which the long duration of the symptoms and the history of trauma complicate the question somewhat.

It is not necessary to give all these cases in detail, as they resemble each other very closely. In 18 the opening was spontaneous, occurring in 3 cases on the third day of the disease, in 4 on the eighth, and in 1 as late as the twelfth day. The 2 cases, those of Duke and Murphy, in which the hemorrhage followed upon operative interference, have already been given above. The common carotid artery was ligated in 7 cases, 4 of which recovered, the other 3 dying of secondary hemorrhage or of cerebral softening. Of the 13 patients in whom the carotid was not tied, all died but one. He was apparently saved by syncope, though the hemorrhage was supposed to have come from the internal carotid artery. Autopsies were obtained in 8 of the 20 cases, showing perforation of the internal carotid artery in 5. The source of the hemorrhage proved to be the internal maxillary in one case, a branch of the external carotid in one case, and the tonsillar artery in one case.

In the fatal cases without autopsy, and in the cases which recovered, the hemorrhage was attributed to the internal carotid in all but one. In that case the ascending pharyngeal artery was thought to be the vessel involved, but upon what grounds does not appear in the history. It may be well to give brief details of two of the most striking cases in which the diagnosis was verified by autopsy.

The first case is that of a man, forty-four years of age, of previous good health, whose symptoms were those of an ordinary acute sore throat. Müller,[1] who reports the case, first saw the patient on the seventh day of his illness. There was then great swelling in the region of the left tonsil. There was no fever, and but little pain, except on swallowing. The patient had expectorated a little blood mingled with pus. The treatment consisted simply of cataplasms and cold drinks. The hemorrhage increased in amount and the patient died on the following day. On autopsy an abscess cavity was found in the left tonsil, and at the bottom of the deep cavity, filled with clotted blood, was the internal maxillary artery, its walls thinned and ulcerated. The carotid and other vessels were normal. It would seem that local pressure, had it been employed, might have checked the hemorrhage in this case.

The second case is that reported by Vergely[2] in 1886. A man, thirty-four years of age, was taken sick on July 26th, and entered the hospital on the 30th. The pharynx, palate, and faucial pillars were intensely red. On the left side there was swelling of the soft palate and anterior pillar, and projection of the tonsil. There was great resistance everywhere to the finger, no fluctuating point could be felt, nor any pulsation. The pain and swelling extended from the back of the throat to the angle of the jaw, and later to the mastoid region and below the hyoid. The patient was pale and prostrated. Surgical treatment was deferred for the development of fluctuation. On July 31st the symptoms were worse, but there were still no signs of pointing of pus. On August 1st the condition was the same. The tonsil and adjacent parts were of a dark red color. Vergely was about to puncture the tonsil when the patient showed him a little expectoration of mingled pus and blood. The operation was then again deferred to the next day, but in the afternoon the patient died with a sudden profuse hemorrhage. On autopsy no suppuration was found in the tonsil or pillars, but behind, in a little retro tonsillar pocket, were some large black clots and bits of

[1] Loc. cit. [2] Loc. cit.

necrotic cellular tissue. The internal carotid artery was cut in two about two centimetres above its origin. The upper end of the vessel was not found.

In this case, as in two others of our series, the operation had been deferred for a day or a few hours and the surgeon thus escaped the charge of having precipitated the hemorrhage. But, on the other hand, had the incision been made early, without waiting for signs of fluctuation, the ulceration of the artery might have been prevented and the life of the patient saved.

In seeking an explanation of the spontaneous rupture of the carotid artery in phlegmonous inflammation of the throat, it has been suggested that there must be present some general constitutional dyscrasia, or perhaps an impaired state of the walls of the vessel, due to previous attacks of inflammation in its neighborhood. In only four of our cases was there any such cause for the accident. Two patients were suffering from scarlet fever when the throat affection began, and a third was said to be subject to abscess of the tonsil. In Duke's case the blow on the head was undoubtedly a most important etiological factor.

Vergely[1] believes that the vicinity of the air passages is the great local exciting cause of the accident. Microorganisms and foul gases are constantly inspired and expired and may easily give a septic character to the pus in the neighborhood. According to Verneuil,[2] the outer arterial coat becomes thickened in an abcess cavity, if neither fever nor septicæmia occurs. But if these complications arise, the protecting cover disappears and the artery is denuded. In angina the pus and gases confined in the pharyngo-maxillary space, kill the arterial wall before compensatory hypertrophy has time to take place. Probably the septic character of the pus combined with pressure are the important agents in eroding the artery. Hence the supreme importance of relieving the tension of the parts even if suppuration has not yet taken place. Bosworth[3] tells us that we may expect the formation of pus by the end of the second or on the third day. In protracted cases, lasting ten days or two weeks, suppuration is not delayed, but the abscess is probably deeply seated in dense tissue and approaches the surface slowly.

I have already said that the hemorrhage occurred in three of our cases on the third day, so that the accident could hardly have been anticipated. It should be noted that in two of these cases scarlet fever had been present for a week or more, which may account for the rapid yielding of the arterial walls.

It is rather remarkable that the great majority of the patients were men. The sex is noted in sixteen cases, and of these twelve were male, one was female, and three were very young children. This preponderance of the male sex naturally suggests syphilis as an etiological factor, but this disease is not mentioned by any observer.

Conclusions.—1. In quinsy, the inflammatory process is usually situated without, and not within, the tonsil. 2. If pus forms it should be evacuated at the earliest possible moment. 3. Unless there are signs of pointing elsewhere, the incision should be made through the soft palate directly backward. 4. If the tension of the parts is very great, the incision is indicated, even though pus has not formed. 5. If ordinary surgical care is exercised, there is no danger of wounding the internal carotid artery. 6. In cases of deep-seated inflammation, in which the pus comes to the surface slowly, erosion of the arteries in the neighborhood may take place. In such cases, therefore, we must be ready to deal with arterial hemorrhage at the moment the abscess discharges into the pharynx.

Senile Vesical Irritation is often promptly relieved by a ten grain dose of phenacetin at bedtime.—GREEN.

"MODIFIED" MILK—BY PRESCRIPTION—MILK LABORATORIES, ETC.[1]

BY W. P. NORTHRUP, M.D.,
NEW YORK.

THIS meeting is in the interests of fresh and clean milk for infants and invalids. Reports say our present milk supply is a mixture twenty-four and thirty-six hours old. The question is, can fresh and uncontaminated milk be obtained; how, and where, may it be obtained? Lastly, concerning an improved form of milk feeding for infants.

The topic which has been assigned to me is, "Modified Milk by Prescription—Laboratories," etc. As there are but two all-around illustrations of my topic in the world, and but one in New York, I can best compass the ground by speaking of this plant, and what it seems to be able to do for us toward meeting our demands. A milk laboratory must control its primal milk supply. I shall, therefore, bring this paper into harmony with the intent of the meeting by beginning with the dairy. Laboratory, prescription writing, and general indications will follow. I may say briefly, for those not familiar with the work of this Section, that we are speaking of a milk laboratory recently started in New York, a duplicate of that in Boston. Its function is, having taken fresh cow's milk, to change its relative proportions of fat, sugar, and albuminoids to the relative proportions of the same found in good average breast milk. This prepares the way for rational substitute feeding and such other modifications as invalids may require.

Cows.—Animals of quiet temperament are selected from native good grade stock, avoiding the strictly butter breeds—inexpensive, good milkers, such as tend to get fat when undisturbed. These are carefully inspected every month by a veterinary surgeon, and any cow which is not entirely well is thrown out. The stables have water-tight floors, manure is carried to a distance, certain amount of breathing space secured to each animal, etc.

Bedding for the cows is white sand four inches deep. It has been necessary to abandon the use of straw; some bacterial growth occasionally got from it into the milk, causing an unpleasant taste.

It is considered desirable for infant food to use a difficult-creaming milk, *i.e.*, a milk from which the cream rises slowly—the fat globules being small, and remaining long in emulsion.

The feeding of the cows is such as will secure alkaline milk as near as possible. But what is considered more important is to procure the milk of a cow in her normal condition, not over-stimulated. What is to the dairyman's interest in quantity of milk is considered opposed to the interest of milk for infant feeding. On the other hand, a strictly butter cow is not considered a baby's cow. The baby's cow *par excellence* is the cow best calculated to raise her own calf upon her own milk.

Modifying Milk.—On its arrival at the laboratory the milk is less (at present time) than two hours old. Immediately it was drawn, the glass jars into which it was drawn were put into an ice and water mixture, and cooled to 45° F. In its journey to New York it rises two degrees, but still remains below 50° F., a safe limit against rapid bacterial growth—so found by experience. The first act of modifying is to pass the milk through a centrifugal machine and whirl out the cream at the highest and innermost level, the separated milk next, and leave against the peripheral wall any impurities that may have fallen into the milk, such as hair or particles of dust. The speed of the centrifugal cream machine is about 4,400, the lowest that will "separate." A low speed is thought to break the fat-globules less—almost none.

We have, then: 1, cream sixteen per cent. fat (stable percentage); 2, milk free of fat; 3, against the wall any impurities. These are removed at intervals and the machine cleansed.

The freshness and cleanness of milk has come to mean

[1] Read before the Pædiatric Section of Academy of Medicine at a so-called "Milk Meeting," October 12th.

more and more to baby feeders, and will be touched upon by other speakers more fully. Suffice it to say that for "modifying," milk must be fresh.

The following is the history of certain milk coming daily into New York from a farm in Westchester County. At 4.30 A.M. milking begins; at 8.15 the milk is delivered at the milk laboratory, having in that time been in an ice-and-water mixture an hour, and upon the cars 40 minutes. Adams Express Company gets from the farm and transports to the city, as express matter, this fresh milking. It is thus possible to get fresh milk. As to its cleanliness, precautions are taken so that the hands be clean, the udders clean, and the receptacle clean—in this case a specially constructed glass jar is used.

The modifier at the laboratory has, then, for recomposing milk on the breast-milk type, 1, a cream of stable percentage; 2, a clean separated milk without fat; 3, twenty per cent. milk sugar solution; 4, distilled water; 5, lime-water. All of these ingredients are freshly prepared daily.

Nature does not seem to run in routine milks. Breast milks differ in all constituents in a remarkable manner, especially in polite modern society. Yet it may be affirmed from experience that all infants can be satisfied upon a limited range of variations.

Practical Workings of this System.—At the Presbyterian Hospital and outside, I have had under observation something over twenty cases, and as result of this experience I may attempt some suggestions to those for the first time prescribing. Our daily rounds are made at a definite time. The babies who have been sunning in the glass roof-house are returned to their cribs, have taken their feedings, are in their best moods. The daily notes of the nurse, with temperature chart and milk prescription, hang at the foot of the bed. Upon a glass topped table is a collection of diapers labelled with the baby's names. As the rounds progress each case is considered with all the data at hand—child, history, chart, notes of successive days, prescriptions, passages. We have agreed upon certain forms of description so that we may understand each other.

Dr. Rotch has put into our hands a good working basis for recomposing milk on the breast type. In round numbers it may be stated as follows:

Good breast milk in a multitude of cases has been found to vary within certain high and low averages. For instance:

Fat	4 per cent.
Sugar	7 "
Albuminoids	2 "

represents a high order of breast milk, and

Fat	3 per cent.
Sugar	6 "
Albuminoids	1 "

represents a light breast milk, but still a breast milk upon which infants were thriving when the examinations were made.

In round numbers, then, consider cow's milk to be:

Fat	4 per cent.
Sugar	4 "
Albuminoids	4 "

The last ingredient is four times the amount of the weaker breast milk albuminoids. Very well, suppose we say we will divide it by four distilled water; we then have made our albuminoids 1 per cent. as desired, but where is the fat and where the sugar? Each will be 1—1—1, and the lightest good breast milk is 3—6—1. Now, with our prescription blank in hand and a well-equipped laboratory near by, we may go to work in somewhat exact methods, and subsequent experience will enlighten us still further. Whatever we do with it, the milk is a good article to begin with.

When an infant comes into the baby ward of a hospital it is sure to be a pretty poor thing. It comes from poverty; its mother must go out to work; its care and feeding are problematical. Suppose it is four months old, and it has been fed on condensed milk. It is desirable to begin feeding on a good milk of about the same proportions that it has been accustomed to. If condensed milk, the albuminoids will be about one, with the ordinary dilution. This ingredient is fair, but the fats are very low. So let the prescription for our poorly-fed, marasmus baby of four months read:

Fat	2.50 per cent.
Sugar	5 "
Albuminoids	1 "
Lime-water	$\frac{1}{16}$ by bulk.
Heat to	167° F.
Feedings	10
Amounts	℥ iv.

The passages will, no doubt, furnish abundant reasons for modifying the milk later, but at first it is desirable to change the proportions slowly. One baby was brought to the ward because its mother was a patient in the medical ward above. It had been fed on cow's milk diluted. Its passages were curdy, mucus in strings and masses abundant, the whole colored as though a solution of Paris green had been poured over it. Here was a baby but temporarily disturbed, age about six months. Prescription:

Fat	4 per cent.
Sugar	6 "
Albuminoids	1 "
Lime water	$\frac{1}{16}$ by bulk.
Heat to	167° F.

For convenience we often speak of the above prescriptions as 2.50—5—1 and 4—6—1, the fat, sugar, and albuminoids being always enumerated in the same order. Two days later the ingredients were increased to 4—7—2; for the moment you can get a baby on the maximum average of good breast milk it will thrive quickly. The passages will become smooth and homogeneous, yellow will crowd away the green, and at length a yellow pasty stool will show that the infant has come to take his own food.

In modifying milk for a child new-born, the problem is not so complicated. Begin with a light breast milk, 3—6—1, gradually increasing. Here the indications are fairly leading. On the other hand, when an old-fashioned nurse has exploited her time-honored fads, from rum and molasses to good old-fashioned cow's milk, such as the pilgrim fathers and her sire were fed upon as babies, when the baby has begun to have frequent explosive watery passages, Paris green in color, with curds and mucus, then you come to a baby that will tax your judgment to prescribe milk for. How shall you hitch it on to the previous series of feedings? The aim is still to make the junction as smooth as may be. Begin with a light breast type. If six months old, say:

Fat	3 per cent.
Sugar	5 "
Albuminoids	0.45
Feedings	8
Amount	℥ vi.

It is well regularly to order modified milk heated to 167° F. (Pasteurized) after the handling and exposure required.

All babies, as you know, are liable to have dilated stomachs from over-feeding. The quantity of modified milk needed to sustain a baby is probably a trifle more than natural breast milk, but in cases of dilatation the quality may be so modified as to regularly diminish the quantity and restore the viscus. So, in ordering an increased quantity, reflect if it will not be better to increase the quality instead.

To such cases of green mucus and curd passages we have usually given calomel, one-tenth grain triturates every hour till freely purged. Thereafter Squibb's bismuth subnitrate, ten grains every two hours, or oftener. We use no form of opium.

As to Weaning.—Then again, it is desirable to try and ascertain what the quality of the breast milk is and order the substitute feeding to correspond. Remember that you

are to modify from 4—7—2, the average high-grade breast-milk, to 4—4—4, the cow's milk. Start with 4—7—2, two days later drop the sugars one-half per cent. and raise the albuminoids one-half, or 4—6.50—2.50. Three days later make the proportions 4—6—3 and have two of the feedings contain one-half oatmeal jelly, or other cereal preparation. So continue, dropping the sugar per cent. and raising the albuminoids, so that in ten days, without the baby's stomach being surprised, it will come to take full cow's milk, bread and milk and is weaned. Breast milk is very flat to taste. Babies that once get any other food prefer it to the breast milk. They like the cane-sugar sweet.

As to my results, my answer is the number of cases is too small thus far. I have seen two wretched marasmus babies restored to good vitality by this feeding. They were emaciated, rickety, big-bellied, greedily filling themselves with any fluid food, and having numerous watery, explosive green passages. It was nearly impossible to keep them warm, they passed urine in large quantities, and were always wet. These two seem the best triumphs.

An adult patient in a private hospital room had not been able to keep on his stomach any food for ten days before coming to the hospital. A little iced champagne was his sole nourishment, so he said. He was put upon a full cow's milk which had been passed through the separator. His feeding was a fresh milk to begin with, a clean milk (its impurities having been left in the machine), and upon milk in divided quantities and regularly administered. In one week he took beefsteak, and is now walking daily in the roof promenade and sleeping the entire night.

I have known the insipid taste of modified milk to interfere with the thorough trial of feeding. If a child has been fed on a sweetened condensed milk it does not prefer to take a tasteless article. If the mother will not be firm and starve it to the new food, there is but little hope of success.

Finally, it is possible now to obtain in New York a fresh milk and a clean milk.

As the digestive capabilities of infants differ, no routine mixture can prove successful, and a variety in percentages of the constituents of milk must be employed to compass perfect nutrition.

Among the reports of progress in medicine, it may be asserted that in the modifying of milk by exact methods a right step has been taken.

57 East Seventy-ninth Street.

LESIONS OF THE SPINAL CORD WITH AND WITHOUT FRACTURE—AN EXPERIMENTAL AND CLINICAL STUDY.[1]

By THOMAS H. MANLEY, M.D.,

NEW YORK.

In these notes brief reference will be made to cervical traumatisms only of the spinal cord and column. This list embraces no experimental cases, and little is attempted in this synopsis except to very briefly give a few of the more dominant clinical and pathological features of those injuries in which the momentum of force is borne by the neck chiefly, with resultant intrinsic or extrinsic lesions of the spine, as elsewhere [2] the subject has been set forth more fully and systematically.

Case I. *Fracture of Posterior Cervical Arch of Fourth Cervical Vertebra.*—Fig. 1 is a photograph of the posterior aspect of the apophyseal arch of the fourth cervical vertebra. The arch was fractured through the spinous process and through the transverse process on each side. Patient was a sailor, who fell from a mast, about twenty feet, striking on the back of his neck. Immediate paralysis. Laminectomy on the day after admission, when fragments were removed; great hemorrhage during operation. No mitigation of paralysis followed, but pain became intensified. Excessive secondary hemorrhage on third day, which was controlled with difficulty. Death on the fifth day, from exhaustion and consecutive meningitis.

This case was one of unusual interest, inasmuch as it demonstrated that there may be immediate and extensive destruction of the cord without displacement of the fragments being discovered on operation, as there was none here; and besides it was an instance which proved the

Fig. 1.

utter futility of section, even when symptoms of medullary compression are unequivocal.

The explanation of this lies in the *modus operandi* of injury. The cord is evidently crushed through by the dissundered fragments, which are driven in on the vertebral bodies; but, by their own resiliency and their ligamentous attachments they are immediately retracted and spring into place. Fig. 2 exhibits the interior aspect of this broad fractured bone plaque. After the removal of this bone there was left a large, open hiatus, at the bottom of which the nude dura mater appeared, without any appearance of laceration. Now, in order to

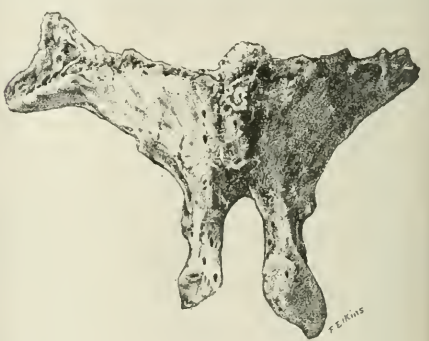

Fig. 2.

provide for the support supplied by this large loss of bone, the head was placed in a cuirass of gypsum.

Herein lies one of the great difficulties in laminectomies in this situation after the bone is removed; as it is never reproduced in the osseous chain, the power to support and balance the head is lost, and henceforth some sort of an apparatus must be always worn.

Case II. *Fracture through the Left Lamina of the Fifth Cervical (Diagrammatic)* (Fig. 3).—Patient, a man aged forty, while intoxicated fell into a bulkhead. Paraplegic on admission into Harlem Hospital; movable spinous process of the fifth cervical. Had great pain in the neck, which was rigidly locked by muscular spasm. Refused operative measures. Sudden rise of

[1] Abstract of an essay read at Omaha City, Neb., May 29, 1893, with new cases added since, all cervical.

[2] Transactions of National Association of Railway Surgeons, 1893. Railway Age Publishing Co., Chicago, Ill.

temperature on sixth day, with muscular twitching in the muscles of the face. Died of cerebro-spinal meningitis on the seventh day, being highly delirious before the end came.

At autopsy, which was hurriedly made, it was dis-

Fig. 3.

covered that there was fracture through the left lamina, with displacement to the right, and free hemorrhage into the spinal canal, with a large extravasate into the adjacent muscular tissues of the neck. As an autopsy was only permitted under protest, we did not venture to remove, for inspection and the camera, the entire cervical segment. Cavities not opened.

Case III. *Multiple Fracture of the Fourth and Fifth Cervical Vertebræ.*—Fig. 4 is an illustration of a speci-

Fig. 4.

men which was removed by me with considerable difficulty on autopsy. The patient from whom it was taken was mortally injured by a fall from the Elevated Railroad structure, in this city, on June 14, 1893. He fell about twenty-five feet headlong, striking on the back of his neck and shoulders. He was immediately paralyzed in parts innervated by the spinal nerves below the cervical plexus.

Dr. Matthew D. Field, the chief surgeon for the Manhattan Elevated Railway Company, saw the case once with me in my service. The question of operation, a laminectomy, had been raised. He survived two days in a painless state, and died of a progressive asphyxia, the temperature mounting to 105° F. just before death. At *post-mortem* examination, on section through the posterior arches, no fracture could be found; but there was an enormous hemorrhage into the spinal canal and all the overlying soft parts. It was only when the vertebral segment was detached at the occiput, lifted out and completely stripped of all its muscular and ligament-

Fig. 5.

ous attachments anteriorly, that the extensive fracture had been discovered. The left vertebral artery was found torn in two at the junction of the fifth and sixth vertebræ.

This case also demonstrates the futility of operations in many of these cervical traumatisms; besides, it impresses the importance of always resecting completely the damaged segment of the spine entire, in all fatal spinal injuries in which an autopsy is permitted.

Case IV. *Fracture through Posterior Arch (the Left Lamina) of the Fourth Cervical Vertebra, with Rotation*

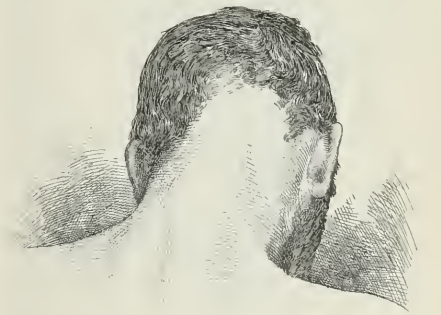

Fig. 6.

of Fragment Outward—Recovery, with Marked Deformity—No Paralysis.—Fig. 5 is from a patient, twenty-six years of age, who sustained a fracture through the posterior arch of the fourth cervical. This photograph was taken in the latter part of July, 1893, four weeks after injury, when the head and neck were in cuirass adjustment of gypsum.

On June 26th he was injured by the rebound of a "sweep" on the windlass of a derrick. He was struck with such force on the back of the neck that he was knocked down on his face, and lay for some minutes in

an unconscious state. Was treated by rest in bed with the head well braced. A distinct fracture of the posterior arch, with marked mobility and lateral displacement, was detected on admission. There was no paralysis at any time, but for a while he quite lost control over the head, which could be moved only when lifted.

After six weeks spontaneous readjustment with osseous reposition had so far advanced as to permit the removal of

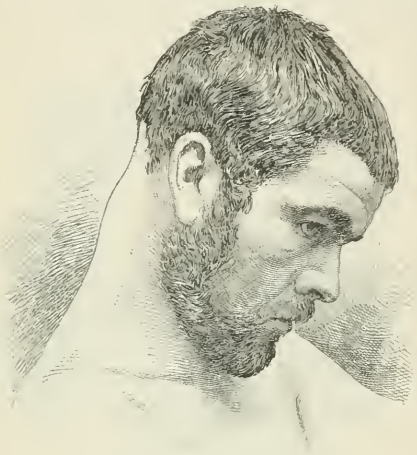

Fig. 7.

the plaster cast, which had been applied ten days after injury

Now (September 1, 1893), as is seen in Fig. 6, from a posterior view, the head inclines strongly to the right, and the cervical arching to the right side is unmistakable. It is quite impossible for him to raise the head without drawing the entire thorax backward.

The above cut (Fig. 7) indicates the present displaced position of the twisted posterior arch. As there is now a distinct hollow felt under the finger in the median line, posteriorly, it is clear that the spinous process is displaced outward, and in further proof of this the spinous tubercle can be felt quite distinct in its new situation.

Fig. 8.

This case is a typical one of fracture through the posterior plane of the spinal column, with distinct and permanent deformity, yet not a trace of paralysis. It is essentially a "broken neck," and it tends to support a conviction which I have long held, viz., that a fracture of the spine is not by any means incompatible with the full functional integrity of the medulla spinalis. This, like nearly all apophyseal fractures, resulted from direct violence. The large mass of callus thrown out plainly indicates the active osteogenetic properties resident in the osseous roots of the vertebral bodies, and that union here is as prompt and effective as in any other bone in the body. At the present time he suffers from torticollis, dependent on the displaced bone. This condition must remain.

It is hard to conceive here what good could have resulted from an operation. Nay, on the contrary, much harm would have followed through mutilation of the parts, sacrifice of bone, and exposure of the cord.

Fig. 9.

Fig. 8 is a schematic view of the nude bone, indicating the seat and extent of fracture. It is seen that there is a fracture with complete detachment of the posterior left lamina; that the canal is exposed and the fragment is drawn far over to the right side, in which situation it now is fixed, and by its pressure from beneath causes a hypertrophy of the integument; besides, there is a painful neuralgia through compression of the nerves. It is clearly apparent that the practical loss of the posterior arch as a means of support must occasion a weakness in the segment of the vertebral column, and leave a permanent "wry neck," or require a prothetic adjustment to maintain the head in an upright position.

Fig. 10.

Case V.—*Double Fracture of Posterior Arch of Fourth Cervical Vertebra.*— Fig. 9 is a diagram of a spinal injury. This resulted from a fall of twenty feet, the patient, a young man, striking on his neck and back of his head. The case ended mortally on the seventh day. As is seen in the cut there was no displacement found on autopsy; but without doubt the fragments had been driven in on the cord, for it was reduced to a pulp underneath.

There was a large, bloody extravasate into the spinal canal, with evidences of advanced inflammatory changes in the meninges. This is another example yet of the uselessness of operation in many of those fractures which are limited to the cervical segment of the spine.

Case VI.—Fig. 10, with a few notes on the case, I am permitted to report by the kindness of Dr. J. W. Wright, of Bridgeport, Conn., under whose care he was. The patient, a young man, aged nineteen, was injured on January 19, 1880, by a fall from a trapeze horizontal bar. He fell, striking on the back of his head, a distance of about seven feet. He was instantly paralyzed from the shoulders down, though consciousness was in no way affected. There were no external marks of violence. No special line of treatment for a time was tried, as it was thought recovery would be impossible. But he gradually recovered sufficiently to walk, with the aid of crutches and a support, one year after the injury. However, he always remained an invalid, though living eleven years, when he died of a bladder affection.

On inspection of the cervical vertebræ it was found that the fifth and sixth had been fractured through their arches and bodies; that they had been partly telescoped into each other; a sort of impacted fracture had occurred.

The precise point of medullary compression had been just

Fig. 11.

opposite the sixth vertebra (Fig. 11). Dr. G. M. Hammond, of New York, made a microscopical section of the cord. At the point of compression it measured one eighth of an inch in its antero-posterior diameter, and three-eighths of an inch transversely. The cord had been in strong alcohol and Muller's fluid three months when these measurements were made. As the crushing was so low down in this case, we can understand why it was that there were no symptoms of asphyxia at any time.

It was maintained by some of the speakers at a meeting of the Neurological Section of the New York Academy of Medicine, before which this case was first reported, that an operation might have saved the patient by relieving the cord-pressure. But how in the world an impaction and telescoping of the bodies could be dealt with safely in this situation it would be interesting to know. Indeed, surgical intervention in the presence of such an extensive disorganization of tissue must have been promptly mortal in its consequences. As a consecutive measure after ossification was complete, it might have effected some relief.

Fracture of Fifth Cervical Vertebra.—Mr. D. Livingston Davies (M.R.C.S.E.), of Nottingham (Borough Asylum), in the issue of the London *Lancet* for June 22, 1893, submits a remarkably interesting case of cervical fracture of the spinal column in a healthy male lunatic, of twenty-nine years of age. It appears that on the 21st of January, in the morning, he was suddenly seized with a suicidal tendency, and pushed his head through a square of thick glass; however, without inflicting much damage to his head. The same night he was under the continuous supervision of an attendant. Shortly after lying down he jumped up, and with great violence jammed his head against the wall of his compartment. After his second plunge he fell helplessly to the floor. He was temporarily stunned by the fall, but in a few moments fully recovered consciousness, complained of pain in his neck, and said that he thought he was paralyzed. No deformity could be detected. Motor power and sensation were wholly lost for three inches above the nipple line; respiration was wholly diaphragmatic; knee-jerk was absent. Twelve hours after the injury his temperature suddenly went up to 102° F. January 22d, temperature 103° F. in the morning; at 1 P.M. it was 104° F.; at 5 P.M. temperature 104.6° F.; at 7 P.M. temperature in right axilla was 104.8° F., in the left 103° F.; at 11 P.M. temperature was 104.2° F. January 23d, 1 A.M., temperature was 105.2° F.; at 3 A.M. 105.3° F. Patient was conscious until an hour before his death, when he became delirious, and died at 4.15 A.M. Death took place apparently by asphyxia. Temperature ten minutes and thirty minutes after death was 106.6° and 106.2°, 105.8°, F.

On *post mortem* examination, twenty-nine hours after death, no fracture of the skull was detected, nor evidence of trauma of the brain. A T-shaped fracture of the body of the fifth cervical vertebra was discovered, splitting the body into three parts with a V-shaped fracture through the posterior lamina, near the junction with the transverse processes.

No displacement of the fragments was noticeable.[1] On opening the vertebral canal, the *meninges bulged* out, and on incising these a large amount of dark blood escaped, being sufficient in amount to cause some compression of the cord. As it was decided to preserve the body specimen the cord was not examined.

Remarking on this spinal injury the author says "that it is interesting to note, 1, the manner in which the vertebra was fractured, by butting the head, without injuring it, in a room six by ten feet; 2, the short period of unconsciousness; 3, total absence of the knee-jerk, with limitation of perspiration to the sensible parts of the body, and difference of thermal state in the axillæ."

The post-mortem showed that no good would have resulted from trephining, the performance of which had been under consideration. I have quoted this short but valuable report, with comments, almost verbatim, and find that it presents so many highly interesting and practical features that it will bear a further analysis and review with advantage.

Etiologically the case is a puzzle; for how a man could fracture the cervical segment of the column without battering in his cranium first, by any sort of butting, is quite incomprehensible, and is utterly incompatible with all laws of physics. It would seem more probable that he must have dove off the bed, head foremost, on to the floor, thereby projecting his whole body against the head and the cervical isthmus.

Clinically the case is a typical one of serious spinal-cord lesion. He was immediately paralyzed. That meant that the cord was mortally crushed; which is always a grave symptom. His temperature shot up suddenly and kept on mounting even after he was dead. That is an invariable phenomenon when acute meningeal inflammation develops after a traumatism of the cord. He died asphyxiated; ascending meningeal inflammation, as soon as it reached the roots of the phrenics and respiratory nerves of Bell, inducing, simultaneously, respiratory inhibition, medullary hyperæmia, and cerebral congestion, with thermal and mental derangement.

Pathologically, though no minute examination of the cord was made, it was specially interesting, for here we

[1] Italics mine.

had a fracture completely smashing through both planes of the column, and yet there was no displacement.

He had free intra-dural hemorrhage. I have always maintained that primary intra-dural hemorrhage never occurs after a traumatism of the column unless there has been a fracture or structural disorganization of other parts.

Therapeutically it supports my position, too, that there are no definite symptoms connected with vertebral fracture; that there rarely is depression of the fragments, and that when there is, the cord is generally irreparably destroyed. I have taken pains to investigate the dime-museum case of "the man with the broken neck," Barney Baldwin. Going there I found a large, heavy, middle-aged man, with his head in a cage, which had a brace attachment. There was no cervical deformity visible. He refused to permit me to carry my hand over the spinous process, or indeed to touch his neck at all. I offered to pay him liberally to call at my office and permit me to make an examination and report a full description of his case to the profession. This he would not do. I have written to physicians in Birmingham, Ala., some of whom have been there all their lives, yet none have any knowledge of him.

To my mind the case is one on a par with the usual dime-museum exhibits. This is all the more evident when we read Baldwin's own story in his book, a copy of which I secured. He says "the accident was caused by an engine becoming unmanageable, which was pushing a train of cars, when I was knocked off the caboose, and was run over by the engine and six cars." It said that Barney had his neck broken, together with his right arm, both legs, and five ribs. His watch was crushed out of sight "into his bowels, and an iron bolt was lost sight of in his collar-bone." The arm was made good by a new silver joint. Besides all this, the fourth, fifth, and sixth cervical vertebræ were smashed, etc. I would not have noticed this piece of imposture as one of extensive cervical fracture of the column, were it not that it has been chronicled by some of our medical journals as "one of the marvels of our time," "Barney Baldwin, the Broken-neck Wonder."

Summary and General Conclusions in Cervical Lesions of the Spinal Column Attended with Fracture.—The general conclusions arrived at after a study of cervical fracture in man and experimental observations on animals justify us in maintaining:

1. Grave injuries of the spinal cord, from injury in the neck, without fracture, are rare.

2. When paralysis immediately follows cervical injury it clearly establishes the fact that the cord has borne serious damage.

3. That fractures which involve the respiratory centres (from the atlas to the fifth) are almost inevitably mortal.

4. Those below this point are sometimes within the range of operative relief when the apophyses alone are involved, and are not so dangerous to life.

5. Fractures through the anterior osseous plane of the vertebral column, the bodies in the cervical and other regions, are not recognizable during life, and are much more common than is generally supposed.

6. The apophyseal type of fracture through the posterior plane is the most easily recognizable, and may be occasionally amenable to surgical measures.

7. Fractures here, as in all other segments of the rachidian structures, are characterized by a tendency to resist displacement, and when this does occur, to spontaneous reposition.

8. The cervical segment of the column may sustain permanent injury without the association of medullary lesions of any description which entail paralysis.

The Chesapeake and Ohio Railroad Company are erecting a hospital at Clifton Forge, Va., where its disabled employees will be sent for treatment. Twenty-five thousand dollars have been appropriated for this purpose.

Progress of Medical Science.

Dieulafoy on the Early Diagnosis of Bright's Disease.—For years past M. Dieulafoy has, both at the bedside and in his much-read work on Medicine, sought to emphasize the importance of divers symptoms which, though often apparently trivial, are none the less significant of the existence of that very common malady Bright's disease. To these symptoms he has given the name of *petite urémie*, or Brightism. He regards albuminuria as an unreliable symptom of Bright's disease. (*The Lancet*). In sixty cases under treatment in his wards during recent years albuminuria was absent in one-fourth. That nephritis really existed was proved in several instances post mortem. In another series of cases albumin disappeared in spite of the continued evolution of the disease. Some patients are albuminuric without being Brightic, to adopt the French expression. Among the symptoms of Brightism M. Dieulafoy mentions auditory troubles. These consist in whistling or more sonorous noises in one or both ears, the causes being multiple (œdema, paralysis of the acoustic nerve, pressure variations). The frequency of these noises may be judged of when it is stated that they were present in thirty-four out of sixty cases. Menière's vertigo was frequently complained of (thirteen times in sixty). Asphyxia of the extremities, first described by Maurice Raynaud, is one of the commonest symptoms of Bright's disease. This begins as formication of the hands or fingers, and then the tips of the latter become bloodless, pale, and numb This dead-finger symptom is found in all forms and in all the stages of Bright's disease. Itching, without possessing the same importance as the above, is sometimes very severe. Frequency of micturition is well known as a symptom of the disease. To this symptom M. Dieulafoy has given the name of pollakiuria to distinguish it from polyuria, many Brightics, in fact, micturating ten or twelve times a day without voiding a quantity above the normal. Cryæsthesia (κρυος = cold), or sensitiveness to cold, is a minor symptom of nephritis. It is generally confined to the lower extremities. Cramps, especially noctural, in the calves of the legs are sometimes severe enough to wake the patient. Epistaxis, chiefly occurring in the morning, is often significant. Electriform shocks must also be counted in this category. At the moment of falling asleep or during sleep the patient is aroused by a single violent shock recalling the effects of an electric discharge. The temporal sign is frequent. Here the temporal artery is distended, dilated, and tortuous without being atheromatous. This is of course due to high arterial tension. The foregoing symptoms of Brightism, if associated in any one individual, are, according to M. Dieulafoy, sufficient to warrant the diagnosis of Bright's disease. He is convinced that many people apparently healthy are in reality Brightics, and this conviction would be shared by most practitioners did they inquire into the presence of these symptoms of Brightism. A confirmation of this diagnosis will frequently be found in the good effects of an exclusive milk diet, which causes the disappearance of these seemingly insignificant troubles. M. Dieulafoy has also applied another test—viz., the degree of toxicity of the urine passed by patients affected with Brightism. He finds that this secretion has in such cases lost a portion of its toxic properties.

Erysipelas of the Bladder.—Dr. Frisch reports the following case, in a patient fifty-two years old, whom he had had under observation and treatment in successive attacks of abscess in the prostate for some time. The patient entered the hospital with one of his usual attacks, but after its symptoms had disappeared there remained a fever that could only be accounted for by the presence of pus, albumin, and a few streptococci in the urine, while the prostate and bladder were sensitive to pressure. Upon the third day, after a severe chill, there appeared

upon the left leg a spot the size of an almond, which presented the characteristics of an erysipelatous eruption, and caused the author to conclude that he had to deal with an erysipelas of the vesical mucous membrane, originating in or caused by the abscess of the prostate. This diagnosis was confirmed by the bacteriological investigation of the urine, the streptococci of erysipelas being recognized both in the plate-cultures and by their characteristic growth in the "stick" cultures, and by their reproducing the disease after inoculation. These bacteriological evidences in the urine increased and then disappeared with the course and termination of the disease in the bladder. The cystoscope showed the mucous membrane deeply red in color, and raised in great folds over its entire surface during the height of the disease. The skin eruption was metastatic—probably through the blood-vessels; this was shown by its origin on the lower leg, far from the original seat of the disease, and by its second appearance on the chest, after having passed over the entire posterior surface of the body and apparently subsided. The patient made a good recovery.—*American Journal of the Medical Sciences.*

Extirpation of an Endocranial Sarcoma. — Dr. Nicolaysen has recorded the following case: A man, fifty years of age, had suffered for many years with right-sided headache, vertigo, and nausea. A tumor in the right temporal region had increased until it reached the size of a child's fist, when he was admitted to the hospital. The patient was not very intelligent. The tumor was solid, elastic, immovable, pulsating, and projected like a fungus from a depression of the skull. There were no spasms and no paralysis. The deeper portions of the temporal muscle were infiltrated with tumor masses, and the whole muscle and the fascia were removed. The tumor was yellowish white, of the consistency of coagulated albumin, and was not surrounded by a capsule. It had evidently started from the diploë. It was only slightly adherent to the dura mater, and this membrane was not infiltrated. There was a depression in the surface of the cerebrum, of a depth of $3\frac{1}{2}$ ctm., and $4\frac{1}{2}$ ctm. wide, made by the tumor. The whole mass, together with 1 ctm. of the surrounding bone, was removed, and microscopical examination proved it to be a round-cell sarcoma. The patient appears to be cured. It is surprising that there should be so few symptoms of cerebral compression with so great a depression in the frontal and temporal convolutions.—*Annals of Surgery.*

The Skin Lesions of Syphilis.—In the *American Lancet* Dr. Cautrell divides these skin lesions into—1st, erythematous; 2d, papular; 3d, pustular; 4th, tubercular; 5th, gummatous; 6th, bullous. 1. The erythematous syphiloderm shows itself between the fifth and seventh week after the appearance of the chancre, and lasts for from one to three months. It may be mistaken for lentigo or freckles, exanthemata, medicinal eruptions, tinea circinata, and tinea versicolor, and the pityriasis maculata et circinata of Duhring. Lentigo occupies the parts exposed to the sun. It is yellowish-brown from the first, and never scaly; the pigment is firm. The reverse of these conditions exists in syphilis. The absence of fever and the darker color of the eruption distinguish this form of syphilis from the eruptive fevers. The medicinal eruptions have some fever and gastric disturbance, with an urticarial or œdematous character of the lesions and some itching. In tinea circinata the lesions are not likely to be multiple. In tinea versicolor the lesions are more of a chocolate brown, and not of so extensive distribution. In pityriasis maculata et circinata the lesions are found in rings and maculæ of all sizes. 2. The papular syphiloderm is a small, hard, round, and raised lesion, of a raw-ham color. It is likely to be at one time or another small or large, scaly or moist, or vegetating. Eczema may be distinguished from the moist variety by there being no lymphatic enlargement, sore throat, or falling off of the hair. Psoriasis is scaly from the first. Look for signs of the initial lesion; do not ask the patient. Lichen planus congregates or localizes itself, and is itchy, which syphilis is not. 3. The pustular syphiloderm may develop from one of the other forms, or occur with them, and may be either pointed or flat, whether of the small or the large variety. Pustular eczema, which is likely to resemble this form of the syphiloderm, gives a history of decided crusting at all times, itching, and no bad odor. In syphilis there is decided ulceration, a bad odor, with crusts stratified, and always polymorphism. Syphilodermata, as a rule, are not limited to those regions affected by acne, as the face, chest, and back. 4. The tubercular syphiloderm shows lesions that vary from the size of a split-pea to that of a hazel-nut; they are smooth, glistening, round, or pointed, of an intense copper color, and may grow singly or grouped, sometimes in circles or crescents, the so-called serpiginous or snake-like character; soon ulcerate and crust; are indolent, and appear late in the disease, the latter part of the second year; are often delayed as long as twenty or twenty-five years. In this variety other lesions are not found. Lupus vulgaris, which is likely to resemble this variety, lacks the history of contamination, does not begin late in life, does not ulcerate with punched-out appearance, and does not progress rapidly. Epithelioma, which resembles the ulcerating form, has one point of ulceration; is slow in forming; secretion scanty, bloody, and viscid; some infiltration; lancinating pains; ulceration most marked in centre. 5. The gummatous syphiloderm consists in a gummy deposit in the skin. At first freely movable under the finger. Its progress is slow; when the skin becomes affected it is not movable; found mainly on scalp and forehead; almost always ends in ulceration; should not be incised. It may be distinguished from furuncle and abscess by its slow, painless progress. 6. The bullous syphiloderm is a late lesion, and seldom seen. Pemphigus and dermatitis herpetiformis, which are likely to resemble it, present lesions containing serum and not pus, and the crusts do not show the horny or rupial character of syphilis.

Treatment of Chorea.—In a recent lecture, delivered at Charing Cross Hospital, Dr. John Abercrombie makes the following suggestions concerning the treatment of chorea in children: Unless the attack is very mild absolute rest of mind and body is essential. Lessons must be given up and the child kept at home lying down. Most severe attacks demand complete rest in a bed with padded sides. In very severe cases the child should be slung as in a hammock. Only in the lightest attacks should the patient feed himself. When mastication is difficult, minced meat, strong beef-tea, milk puddings, milk, and cocoa should form the chief articles of diet. Sleep is of great importance. If necessary, chloral, morphine, bromides, may be administered. Iron and arsenic are the best drugs, though drug treatment is of less importance than general management. Rheumatic manifestations or heart complications should be treated on general principles. In chronic cases douches to the spine, shampooing, massage, and gymnastics, are of value.

Spinal Paralysis of Syphilitic Origin.—This affection is described by Erb under the title of syphilitic spinal paralysis, and by Charcot as syphilitic transverse myelitis. Kowalewsky has recently reviewed its clinical features and differential diagnosis. It is of slow development, occurring chiefly in men between the ages of thirty and forty-five, and bladder disturbance is one of the first symptoms. Many of the conditions present resemble those of spastic paraplegia. But spasticity of gait, when it exists, is not so marked as in lateral sclerosis. Muscular rigidity and increase of deep reflexes are less marked than in spastic paraplegia. There is always increase of muscular irritability, exaggeration of response to heat and cold, and tactile and analgesic response are normal or shortened. An opposite effect is produced in locomotor ataxia.

MEDICAL RECORD:

New York, October 28, 1893.

IDIOTS AND OTHER BACKWARD CHILDREN.

IN 1801, a wild boy was found in the forests of Aveyron, in France, and brought to Itard, the friend and disciple of Condillac. Hoping to find in the instruction of this lad the verification of Condillac's philosophical theories, Itard labored patiently for six years to develop his intellectual faculties by means of sensations. The young savage proved to be an idiot of low grade, and hence unfit for the experiment. But the attempt to instruct him satisfied Itard that it was possible to elevate the mental condition of idiots. The facts he gathered together he communicated to his pupil, the late Edward Seguin, who entered upon the work as a labor of love, and in 1846 published his treatise on the management of idiocy. This treatise placed him forever in the foremost rank of modern psychologists. The work started by him at the Bicêtre, in Paris, has been continued and brought to a higher state of technical perfection by Bourneville. Or, as the fact has been poetically expressed, "Bourneville holds aloft the torch earlier lighted by Seguin."

Itard's pupil consulted nature as to the mode by which the physical powers are cultivated and the mind educated in the infant. So did Frœbel; and out of his axiom, "There is nothing in the mind that was not first in the senses," grew a whole system of scientific sense-training, with gifts, occupations, songs, and movement games. The same idea Kant expresses in a more general way: "All our knowledge begins with experience." Idiocy meant to Seguin prolonged infancy—infancy without grace and charm. The infantile fondness of idiots for bright colors was utilized to teach them distinctions of color and form. Their liking for playthings he turned to good account by instructing them in number, form, and size, through the medium of blocks, cups and balls, and other toys. Words came next, and the meanings of words were taught by pictures. Letters had their place later. The eye, the foot, the hand, were educated by means of steps, dumb-bells, and other gymnastic exercises. The refractory organs of speech were moulded and manipulated until they could utter the desired sounds. After strict familiarity with things came ideas, at first concrete, then abstract as higher consciousness was attained. Though long, this process triumphed. Seguin revolutionized all the foregone conclusions concerning idiocy.

From that time the work has gone on steadily, though slowly, in different parts of the world, in France, America, England, Germany, Denmark, Holland, and Switzerland. In the *Progrès Médical*, June 24, 1893, Bourneville publishes a most interesting record of some of the work done in Paris, at the Bicêtre, where the treatment is at once medical, hygienic, and pedagogic. The patients are first taught to hold themselves erect, then to walk. Their joints are exercised and their limbs are subjected to friction. Baths and the arts of hydrotherapy aid in physical development; and physical culture is advanced by systematized movements, free gymnastics, fencing, and dancing. For the development of speech and correct pronunciation, methods in vogue in deaf and dumb asylums are utilized. Every device is employed to render number and calculation real and intelligible. Exercises in the training of vision are many. Some of these are carried on out of doors in gardens laid out for the purpose. There are gardens of surfaces, of geometric figures, flower gardens, vegetable gardens, orchards, woods, fields of grain, vineyards, etc. Music occupies an important place. There are songs and movement games, together with instruction in vocal and instrumental music. Care is taken to teach the children to distinguish different kinds of sounds. The very first lessons are in the care of the person. Object lessons are given upon the manikin, or upon the child himself, in all the complicated movements required for dressing and undressing, and in the many automatic acts that the normal child learns by imitation. The children at the Bicêtre are taught to wash their faces and hands, to lace their shoes, etc. They learn through doing. Technical training for some trade completes this medico pedagogic system of education. There are seven workshops, where the pupils receive instruction in carpentry, in locksmith work, in printing, tailoring, the making of shoes, baskets, brushes, twine, etc. The results of this method are surprising.

Bourneville classifies idiocy as symptomatic of hydrocephalus, microcephalus, arrested development of convolutions, congenital or pathological malformations of the brain, meningitis or meningo-encephalitis, myxœdema, or cerebral tumors. The paper referred to contains a comparative study of the skulls and photographs of the brains of twenty-two idiotic children, of ages varying from two to seventeen years. Their idiocy was dependent upon different conditions, and their death due to a variety of diseases. They were all typical idiots, and belonged to the same class as the twenty-five patients operated upon by Lannelongue.

The treatment had been that of the system just described, with results encouraging alike to the physician and to the humanitarian. The author calls attention to the fact that many backward children are moral imbeciles. They are unstable, perverse, impulsive, wayward, and disorderly. They reach a certain stage of development. The moral qualities are in abeyance, though the intellectual faculties have fair possibilities. Moral imbeciles possess as much mind as is consistent with a total absence of character.

From close observation and wide experience in the care and treatment of every class of imbeciles, Bourneville arrives at six very definite conclusions, somewhat at variance with theories that have a certain vogue. The surgical treatment of idiocy, he thinks, rests upon a hypothesis which is not confirmed by pathological anatomy. That premature ossification of the cranial sutures

exists in the different forms of idiocy is denied, a partial synostosis being always an exception. Lesions which cause idiocy are generally profound, extensive, varied, and unlikely to be influenced by craniectomy. The diagnosis of premature ossification and thickness of the skull is not possible with our present means of investigation. The reports of most surgeons show that the results of operations are negative, slight, or doubtful. Serious accidents may follow surgical intervention, as paralysis, convulsions, or death. The medico-pedagogic treatment founded by Seguin, and brought to perfection by the introduction of new processes, applied with care and patience and for a sufficiently long time, permits us almost always to obtain decided improvement, and often enables idiotic children to attain some value and social station.

The reason that more is not accomplished for idiots and backward children, lies with the parents themselves. It is very difficult to persuade them that their children are mentally defective. Too often the physician's statement is not believed, and nothing is done in the way of special training. Thus valuable time is lost. Yet idiocy is by no means an uncommon disorder. According to one estimate, said to be very much within the truth, six persons in every thousand are idiots, or of such imperfect development as to be of little or no service to the community. In view of the facts of the case, it is evident that the public has much to learn concerning its duties to idiots and other backward children. As it has been demonstrated that the great majority of the feeble minded are susceptible to physical and mental improvement, the claim is not unjust that all backward children are entitled to special education and training. Ten to twenty per cent. who are received and trained in institutions become bread-winners; thirty to forty per cent. can help themselves in many ways and are but slightly burdensome to their families; and the remainder always need custodial care. From any point of view, from that of selfishness, of humanity, sentiment, religion, or social economics, there seems to be no definite and satisfactory reason why the feeble-minded should not be trained into relative usefulness and become at least partially self-supporting.

CŒLIOTOMY VS. LAPAROTOMY.

We commented some time ago on the sudden adoption of cœliotomy in place of laparotomy by some of the surgeons of this city. While not denying a certain etymological justification to the former term, it seemed to us not altogether unobjectionable for various reasons. Dr. R. P. Harris has been kind enough to send us his original pamphlet, published in 1890, in which he presents with much learning the argument for the change of nomenclature. The argument amounts essentially to this: that *cœlia* means "belly," while *lapara* means "flanks," hence cœlia is the proper word. To this it must be said, however, that *cœlia*, according to Foster, has had in the past four different meanings, viz., the abdomen, the intestines, the fæces, and "any cavity of the body such as the socket of a bone" (Hippocrates).

As we stated before, the word has already been adopted by neuro-anatomists to indicate the cavities of the nervous system. Cœliolymph (Wilder) is the cerebro-spinal fluid, while the root "cele" is in common use in medicine to indicate a cavity.

While laparotomy may not be strictly accurate, therefore, cœliotomy is not inherently much better.

AN ACCIDENTFUL YEAR.

Everyone must have noticed the fact that there has been an unusual and extraordinary number of railroad accidents in this country during the past six months. Collisions, derailments, falling bridges, defective switches, careless trainmen, all these things have combined to make the list of killed and injured tragically large. Taking only a newspaper census, made from two daily papers of this city, one finds a record, according to the *Sun*, of 115 killed and 226 wounded in railroad accidents alone, since May 15th. In addition to this it seems that the accidents from fire, flood, storm, and trolley cars have been also extremely large. The following is the record since May 15th, as tabulated in the paper referred to:

Kind of accident.	Killed.	Injured.	Total.
Falls	71	245	316
Drowning	116	...	116
From trolley cars	44	98	142
Burns, scalds, and explosions	133	92	225
Railroads, to travellers on trains	115	226	341
Disaster, struck by train	55	7	62
Struck by falling objects	15	44	59
Runaways	8	50	58
Run over on street (besides trolley car accidents)	22	105	127
Miscellaneous	538	329	867
Total	1,117	1,196	2,313

This does not include over one thousand lives lost during this period by flood and tornado, nor the two thousand and more who were killed in the frightful cyclone that recently devastated the Gulf coast.

Putting all together, it may safely be estimated that five thousand lives have been lost by violence, and more than twice that number of persons injured in the last six months. A practical evidence of this has been the effect on accident insurance companies. One of the largest of these has recently had to make an assessment on account of the unusual number of accidents and the consequent extra drain on its resources.

It is unfortunate for the professional prophet that the year 1893 was never selected as one of especial woe, for to accidents by flood and field must be added the depressing influence of a panic, and the spectacle of a great country's legislation blocked by the verbigeration of flatulent fanatics. This has been the year when the United States might have been pictured as the Niobe of Nations, with nothing but Chicago to dissipate the tears.

Some of the railroad accidents of the summer are in a measure traceable to the increased traffic caused by the World's Fair and the sudden large movements of wheat occurring at the same time. The result has been that railway officials have been overworked and have got careless. Others of these accidents are distinctly traceable to the non-use or imperfect use of the block system. This system costs the New York Central $40,000 a month, it is said; but that amount is more than saved in the diminished loss of life and in diminished injuries and breakage. Many railroads cannot, or think they cannot, afford to apply this system. Another preventable source

of accident and death is the trolley car. Forty-four deaths and ninety-eight injuries in six months is a shocking total, and quite justifies the application of the term of Juggernaut to the trolley as it now is. It seems incredible that this cannot be prevented, either by a better system of control or the use of proper guards in front of the car.

News of the Week.

Dr. Pozzi, of Paris, on his journey westward, spent a couple of days in Cleveland as the guest of Dr. Dudley P. Allen. During his stay he was given a dinner at the Union Club to meet the Trustees of the Western Reserve Medical College, and the following morning operated before the students and faculty of the school, performing an unusually difficult laparotomy. He demonstrated his method of operation in such cases, sitting between the patient's thighs, using pieces of gauze, folding it together in squares, perhaps a foot in size, and operating through a small incision. The case was one of double salpingitis, due to infection, and was extremely adherent. The removal of the tubes was followed by profuse bleeding, which was held in check by gauze tampons. After the bleeding had been controlled in a degree, a Mickulicz tampon was carried down into the pelvis. I am glad to say the progress of the case has been favorable in every respect. Dr. Pozzi was a very welcome guest, and greatly interested the profession by his methods and by his demonstrated ability as an operator.

The Kansas City Medical College Circular to Students.—We have received a letter addressed to a medical student, signed by the President of the Kansas City Medical College, a part of which will bear quotation: "We hope that you will visit the College at the beginning of the session of 1893–94, September 18, 1893, and become acquainted with officers and members of the faculty and the students. We feel certain that you will be pleased and decide to matriculate with us. In doing so you will find that our requirements for admission are not more exacting than those with which our many students in the last eight years have found it easy to comply, and that we fully appreciate that many applicants are not fresh from school." This is bad on its face, of keeping the standard of admission to a dangerously obliging level. In the East the fashion is the other way.

Wholesale Vaccination.—Within the past few weeks over eleven thousand persons have been vaccinated by the Health Department of this city. No new cases of smallpox have been reported since last Saturday.

Cholera in Berlin.—The Imperial Health Office reports that during the past week there have been seven fresh cases of cholera and four deaths in Tilsit; eight fresh cases and two deaths in Stettin; and three fresh cases in Zerpenschleuse, Prussia. It is believed that the Berlin-Stettin Canal is infected.

Yellow Fever in Brunswick.—Thirty-six new cases have appeared in Brunswick since our last report.

Civil Service Examinations.—Open competitive examinations for the positions of Junior Assistant Physicians and Apothecaries in the State Hospitals, will be held at the office of the Civil Service Commission, Albany, Thursday, November 16, 1893, at 10 A. M. Applicants as Junior Assistant Physicians must be residents of the State of New York, graduates of a legally incorporated medical college, and have had at least one year's actual experience on the staff of a public general hospital. Salary, $800 to $1,500 per annum and board. Applicants as Apothecaries must be residents of the State of New York, at least twenty-one years of age, and must have a license from the State Board of Pharmacy. Salary, $500 to $600 per annum and board. For application blank, address New York Civil Service Commission, Albany, N. Y. Thomas Carmody, Chief Examiner.

Alvarenga Prize of the College of Physicians of Philadelphia.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about one hundred and eighty dollars, will be made on July 14, 1894, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published, and must be received by the secretary of the college on or before May 1, 1894. Each essay must be sent without signature, but must be plainly marked with a motto, and be accompanied by a sealed envelope having on its outside the motto of the paper, and within it the name and address of the author. It is a condition of competition, that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned upon application within three months after the award.

CHARLES W. DULLES, *Secretary*.

The Death of Dr. Walter Vought.—The Managers of the Vanderbilt Clinic, at their last meeting, adopted the following: Since the last meeting of the Board Dr. Vought, one of the oldest of the clinical assistants in the department of Neurology and Medicine, has fallen a victim to typhoid fever. By his untimely death the Vanderbilt Clinic loses a member of its staff who was conspicuous for his skill and diligence, and the profession a physician of distinguished ability and rare promise. Dr. Vought's work in this institution was characterized by a thoroughness and fidelity which commanded the admiration of his superiors, and stimulated the enthusiasm of his associates. His example will leave a deep impression in the methods and discipline of the Clinic, and serve to perpetuate its best traditions.

The Congress of Norwegian Physicians, which recently met at Christiania, held its sessions on a large steamer which moved from place to place. The physicians were thus furnished with fresh air and change of scene while pursuing their scientific work. The example is worth studying and following. Hereafter, instead of hiring a hall for their midsummer congresses, let them hire a boat.

A Diet for Literary Workers.—The *Hospital* advises literary workers to rise early, take a cup of coffee with toast at half-past six, write for a while, take breakfast at eight, write till noon, take a lunch at one o'clock, smoke a pipe after it, take a cup of black coffee at two, write a couple of hours, take a cup of tea at four, write till half-past six, take dinner at seven, winding it up with a cup

of black coffee, take things easy till quarter of eleven, then take a small cup of cocoa, and be ready for bed at eleven.

We should not like the *Hospital* to lay down a diet for medical workers, if it were of the above character.

Studying Medicine in Order to be a Novelist.—Dr. Arabella Kenealy, the author of "Dr. Janet of Harley Street," a novel which has reached a fourth edition, is said to have entered the medical profession with the express intention of bringing its resources to bear upon fiction. Having showed considerable literary talent at a very early age, the burying herself in medical student life for the lengthy period over which the attaining a degree extends was regarded by her acquaintances as a waste of time. But Miss Kenealy is convinced that the time could not have possibly been better spent; that for the study of human nature and a thorough realization of some of its most suggestive phases, the life of a doctor is pre-eminently fitted.—London Cor. *American Practitioner.*

Marriage of Dr. Charles O. Rice.—On Wednesday morning, October 25th, Dr. Charles O. Rice, of 400 West Fifty-seventh Street, was married by the Rev. Father John Hughes, at the church of St. Paul the Apostle, to Miss May Gordon. The wedding ceremonies were on a grand scale, and the church services were largely attended by the many warm friends of the doctor and his beautiful young bride, who was born on the West side, and is the daughter of Mr. Edward Gordon, a well-known and highly respected citizen.

Mütter Lectures.—The Mütter Lectures this year will be given by De Forest Willard, M.D., at the Hall of the College of Physicians in Philadelphia, on Tuesday evenings, from October 17th to December 19th. The subject is "The Surgical Pathology and Surgery of the Spinal Cord, the Vertebræ, and Peripheral Nerves."

A Doctor Sues an Earl and Wins.—It was rather plucky of Mr. Lennox Browne, says the *Hospital Gazette*, to sue the Earl of Annesley in the Bloomsbury County Court, to recover the balance of his fee for a small, but delicate, operation he performed on his lordship's son, Lord Glerawley. It appears that the young nobleman suffered from stammering, and Mr. Browne, who was consulted, advised the removal of a small growth in the throat, to which the Earl consented. Mr. Browne charged thirty guineas for the operation, but the Earl would only pay ten guineas, which he considered an ample fee, as the operation did not cure the stammering. The judge thought it unlikely that Mr. Browne would perform operations on the "no cure, no pay" principle, and gave him a verdict for the full amount. Commenting on the case, the *Globe* very sensibly remarks: "No medical man of repute would pledge himself as to the result of a delicate operation on the throat; still less would he agree to forfeit two-thirds of his fee in the event of failure. No doubt thirty guineas is a pretty high figure to have to pay for an operation which takes only three minutes, and does not produce the desired result, and one quite understands the feeling of Lord Annesley that he has not got value for his money. But then, on the other hand, Mr. Lennox Browne would reply that he had stated the amount of his fee beforehand, that this amount was no more than the custom of the profession sanctioned, and that Lord Annesley had the services of one of the foremost men in that branch of the profession. After all, if one wants to be attended by a man who has a practice which enables him to sell his time at a rate of ten guineas a minute, one must pay for the privilege. When you have ordered a bottle of 1874 champagne, and drunk it, it is not fair to refuse to pay for it on the ground that you could have done just as well on a pint of bitter."

The Queen and the Hospitals.—London newspapers recently announced that the Queen had been graciously pleased to present many bottles of wine to various London hospitals for the use of poor patients. The same papers have carefully refrained from giving currency to the report published in reputable provincial journals, to the effect that the most of the wine in question was the refuse of the royal cellars, and unfit for use in hospitals. It was in very bad condition. Many of the bottles were half empty, and others were so badly corked that the contents had turned sour. It is charitably suggested that her frugal Majesty was ignorant of these defects.

Dr. Charles H. Fisher, of Providence, R. I., Secretary of the State Board of Health, died at the Continental Hotel, in Buffalo, October 21st. He had been in Chicago attending the Health Congress, and while there caught a severe cold. He grew worse on the train and stopped at Buffalo for medical attention.

Temperance and Health. — In view of the many schemes for temperance legislation which throng the political horizon, the report of the Collective Investigation Committee of the British Medical Association, on the subject of "Temperance and Health," possesses a special interest for us. The committee who undertook this work divided the subjects of their investigation into these classes, *i.e.*, total abstainers, habitually temperate, careless drinkers, and the decidedly intemperate. Resultant on their labors in this field of research, the committee give the following table, illustrative of the relative longevity of the persons thus classified:

	Years.
Habitually temperate	62.13
Careless drinkers	59.67
Free drinkers	57.59
Decidedly intemperate	52.03
Total abstainers	51.22

—*The Hospital.*

A Medical Distinction (*Boletin del Instituto Medico Valenciano*, July, 1893).—By an order of the Queen Regent of Spain, all the medical men connected with the university faculties are directed to wear as a distinguishing badge a gold medal suspended by a cordon of the color peculiar to each university.

Recent Bequests.—The will of the late Dr. Parsons, of Providence, bequeathes his medical library to the Rhode Island Medical Society, and four thousand dollars to the Rhode Island Hospital, to establish a free bed in memory of his father, Usher Parsons. The residue of the estate, after paying all of the bequests, is to go to the Rhode Island Hospital. The estate is reported as very large.

The Zoothermic Institute at Rome.—In a contemporary M. Pion gives a description more curious than attractive of a method of treatment which reads like a survival from barbaric times. He writes: "French doctors will not

be sorry to have a recent description of the famous Zoothermic Institute, which provides in perfect style a certain mode of healing much esteemed among Italians. In the abattoirs, fitted up in the most luxurious style, after the latest fashions, and finished only last year, is a special building which I was much surprised to find there. To this place, under the best management, doctors send their patients tortured by rheumatism and gout. Others, anæmic patients, prostrated by the malaric fevers of the Pontine marshes, come there in order to drink blood. The unhappy invalids, without any repulsion, dip their arms, legs, or whole bodies in the warm fluid. The municipality has paid all the expenses of the installation. The prices vary from three francs to seventy-five centimes, while for the extreme poor the treatment is free. There is room for more than fifty patients at a time, and the veterinary inspectors assured me that the results are appreciably beneficial. In a hall above glasses are prepared into which pure blood is poured, freed from fibrin and above suspicion. The animals are previously inspected by the veterinary official. The blood is freed from fibrin by being placed in a kind of round box, hermetically sealed, in which turns a bar of iron, terminated by three teeth. The apparatus revolves after the fashion of an ordinary coffee mill, and the process being performed under cover from the air, no microbe or dangerous germ can penetrate into the liquid."

New York Cancer Hospital.—Dr. George W. Jannan has been appointed Attending Gynecologist to succeed Dr. Clement Cleveland, who has resigned and has been made Consulting Gynecologist.

A New Million Dollar Hospital for New York.—The late Mrs. Mary T. March has bequeathed $10,000 to Bellevue Hospital in memory of Charles March; $10,000 to the Louise Home of Washington, D. C., in memory of the mother of the deceased, and the remainder of the estate to Grace Church, in New York, for the purchase of ground and the erection of a hospital, to be known as the John Pyne March Memorial Hospital for the relief of the sick, aged, and indigent in Grace Church parish. The total estate amounted to about $1,000,000, and the greatest part of this sum goes to the new hospital.

The Madrid Academy of Medicine Prizes. — The Academy of Medicine of Madrid has offered for the year 1894–95 two prizes open to public competition: The Academy Prize of $300, a gold medal, and the diploma of a corresponding member of the Academy, for the best essay on the "Treatment of the Different Clinical Forms, Accidents, and Complications of Diabetes, based upon the Writer's Observations." The essay is to be written in Spanish or Latin. The Alvarez Alcala Prize of $150, and corresponding membership in the Academy. Subject: "Surgical Intervention in Intestinal Obstruction." The essay to be written in Spanish, French, or Latin. The essays must be in the Secretary's possession by May 1, 1894.

A New Hospital Incorporated.—A certificate of incorporation establishing "The New York Throat and Nose Hospital" has been registered in the county clerk's office. The objects of the incorporators are the erecting, establishing, maintaining, and operating a hospital for the reception and care of, and maintaining and giving medical and surgical advice and treatment to, persons afflicted with diseases of the throat, nose, eyes, ears, and lungs. The Board of Managers is as follows: Edward J. Bermingham, M.D.; Andrew Shiland, jr.; Henry Griffen, Charles E. Pell, J. Julio Henney, M.D.; Ferdinand Levy, D. Morgan Hildreth, jr.; Oscar Kress, and C. F. Frothingham.

Obituary.

JOHN C. PETERS, M.D.,

NEW YORK.

VERY few of the older medical men who took part in the active medical affairs of this city during the past generation are with us. Retiring upon laurels faithfully won by hard work, they are being replaced by younger and equally aspiring men, who in their turn will give place to those who are to follow.

But during a long life of usefulness, no one gone or to come, has left or will leave a more enviable record than the good and talented John C. Peters, late of this city, whose death took place at Williston, L. I., on Saturday, October 21, at the age of seventy-four years. The one who would write so feelingly of his contemporaries, and whose biographies were such masterpieces of literary merit, fine sentiment, and interesting incident, has himself become the subject of the last good-by, and has ended his career with a reverent amen. The readers of the RECORD have often, in times gone by, been delighted and edified by the productions of his facile and cultured pen in the lines of thought in which he was interested. Few wrote with greater force or perspicuity on the subject of epidemic influences and their dependence upon germ diseases. His wide reading, unbiassed judgment, and progressive spirit kept him at all times in the lead of all movements calling for high scholarship, and the lofty attainments of good citizenship.

Dr. Peters had practised medicine in New York since 1842. He was born in this city, and was educated at the College of Physicians and Surgeons, and the medical universities of Berlin and Vienna. He was one of the founders, and at one time was President, of the New York Pathological Society, and for many years was editor of the Society's proceedings, was President of the New York County Medical Society, and a member of the New York Academy of Medicine, and of nearly all leading medical societies in the city. He was the physician and personal friend of Washington Irving. Dr. Peters made a special study of Asiatic cholera, and his library on cholera was said to be the most complete in the country. He wrote many pamphlets on this subject. He was associated with Dr. Edmund C. Wendt in preparing a treatise on cholera, and in 1866 wrote Peters's "Notes on Asiatic Cholera," a standard work. Dr. Peters suggested new remedies in the treatment of consumption, Bright's disease, and membranous croup. In 1873 he travelled through the South and Southwest to study cholera, and afterward assisted in preparing a report on cholera which was published by order of Congress. In 1878 he did valuable service in the threatened yellow-fever epidemic. Dr. Peters published treatises on diseases of the brain and nervous system, and assisted Dr. Alexander S. Wotherspoon in translating Rokitansky's "Pathological Anatomy." With Dr. Frederick G. Snelling and others he published "Materia Medica" (1856–60). He retired from active practice about eight years ago, and gave his time to consultations alone until three years ago, when he removed to his Long Island home, where he was stricken with paralysis, to which he ultimately succumbed. Personally, Dr. Peters was a lovable, modest, earnest man, kind and considerate to all, respectful of true merit, and instinctively inspiring in all who knew him a becoming and sincere appreciation of the well-rounded character of a Christian gentleman.

Society Reports.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, October 16, 1893.

S. B. W. McLeod, M.D., President, in the Chair.

Dangers to the Public Health of New York from Overcrowded Population.—Dr. E. G. Janeway opened a discussion upon this subject with some extemporaneous remarks. The overcrowding to which he referred was more especially in tenement-houses. Small tenements on the east and west sides were being torn down, and tall ones, five or six stories high, twenty-five feet frontage, were being erected in their place and were planned to house as many as twenty families. This was said to be the result of economic conditions, the price of ground necessitating the erection of high buildings. But the same thing was observed above the Harlem River, where much ground was unoccupied and could not be so dear Moreover, the very fact of increasing the number of families in a house, or the number of people on a given area, tended to make the price of ground higher still. Thus it would be seen that one solution of the problem of dear ground consisted in restricting the size of the tenements.

It had been said that the new and larger tenements were more healthful than the old, but Dr. Janeway thought this would probably be only temporary, for with age they, too, would become contaminated with filth and disease, and the greater overcrowding would make them more dangerous.

One could hardly find a more marked contrast between the homes of the people of two great cities, as far as it related to overcrowding, than existed in New York and Philadelphia. These two cities were located only ninety miles from each other, and had not a great difference of climate and surroundings. Philadelphia was built up largely of small houses, with one or only a few families in each house, while in New York the tenement plan prevailed, with ten to twenty families in a building. With a view to determining the effect of overcrowding upon the health of the population, Dr. Janeway had compared the vital statistics of Philadelphia and New York during the past ten years, and had found that in Philadelphia the mortality-rate per thousand each year had been about twenty-two per cent., while in New York it had been about twenty-seven per cent., the percentage varying somewhat in each city from year to year, but always remaining higher in New York. Then it would be expected that certain diseases, especially contagious diseases, would be more prevalent in New York, and so it was, typhoid fever being an exception—as might be expected when one considered the difference in the water-supply. In New York the water was brought a long distance, and was comparatively pure; in Philadelphia it was obtained from the Schuylkill, not far from the city, and it was said that typhoid fever there was mostly due to infection of the water.

Since 1883, the lowest death-rate from typhoid fever for a single year in Philadelphia had been 579; in New York the highest number had not attained to 500, yet the population of New York was considerably larger. The death-rate from phthisis, scarlet fever, diphtheria, and measles had been greater, in proportion to the population, in New York than it had been in Philadelphia, during the past ten years. The ratio should be about eight for New York, five for Philadelphia, whereas it had been about eight to four. Thus, for one year the number of deaths from phthisis in New York had been 5,160; in Philadelphia, 2,636. In both cities, however, the death rate from this cause had been decreasing, a fact which he suggested might be due to spread of knowledge of the infectious nature of the disease. The deaths from scarlet fever in New York amounted to 1,242 one year; in Philadelphia, 298; and this was about the usual ratio between the two cities.

In conclusion, Dr. Janeway said it seemed to him that if New York allowed the erection of such tall tenements to go on, we would see in the future serious results, not only with regard to health, but also with regard to morality, and in case of riots difficulty in controlling the passions of the populace.

The Gregarious Caucasian.—Dr. Charles A. Leale had learned at the anthropological department of the Columbian Exposition, that the Chinese had for centuries met one of the evils of overpopulation by sending an apparatus around on wheels in which infected fabrics and articles were disinfected by dry heat, maintained a number of hours at a temperature corresponding to the boiling point of water. History went to show that certain races were more disposed than others to live crowded together. The white race seemed especially to live in thickly populated districts. Negroes and Indians were more disposed to scatter. The evils of overcrowding had been forcibly impressed upon Dr. Leale in his relations to the St. John's Guild. A short absence from overcrowded apartments sufficed to bring about a wonderful improvement in the condition of sick or weakly children.

Dr. J. R. MacGregor thought the experience of medical men in different parts of the city proved that overcrowding was far-reaching in its evil results. Young men saw more cases of infectious diseases than the older members of the profession, which showed that such diseases were more prevalent among the poor in the overcrowded districts. The height of buildings and number of tenants should be governed by the width of the streets. The dangers of overcrowding were enhanced by the practice of making workshops of the apartments and by the unhygienic habits of the tenants, due partly to ignorance, partly to poverty, and partly to want of privacy. The so-called air-shafts, or wells, between buildings, were channels for conveying foul odors, dirt, and contagion from one floor to another. Doctors should act as missionaries and warn the tenants and the public of their danger.

A Sure Check to Overcrowding.—Dr. J. Lewis Smith gave some experience during his twenty years' connection with infant asylums in relation to overcrowding. Early in his experience, when children were brought from surroundings of filth incident to narrow tenements and were put into a hospital where the conditions were little better, he was told by the person in charge that his visits would be useless, for all children who entered there died, and it proved to be so until the conditions were changed. Death of the little ones was a sure check for overcrowding. A pitiful instance, which was but one of thousands, was that of a family in a new apartment-house, containing perhaps twenty families, the plumbing supposed to be modern and sanitary, but not so in fact. The father was out of employment, the mother was haggard from care. The largest of the two or three rooms occupied by the family was about twelve feet square. In the front room a child lay, whose inspiration was guttural, its neck swollen, and presenting the familiar symptoms of malignant diphtheria. The mother said it had been sick four days, too sick to carry to the dispensary. In the adjoining cold room were the three other children—five, seven, and nine years of age—huddled together, trying to keep warm, and awaiting their turn to be stricken with the terrible malady. Two other children were still at the public school!

The mortality among children was further enhanced by women, compelled to work for a living, putting their babies into the care of ignorant nurses, who gave them bad cow's milk and much opium. The society woman demanded a wet-nurse, and although her own babe might live, that of the wet-nurse almost invariably died. Thus, infanticide was practised in overcrowded New York almost as flagrantly as along the banks of the Ganges. And he had not yet mentioned the alarming extent to which abortion was practised.

Dr. L. Landes, whose office was in the lower part of the city, said he had seen a great deal of the evil of over-

crowding in tenements. The mortality in those districts was almost fifty per cent. higher than in private dwellings. There was not sufficient air-space for the number of people in the apartments, the plumbing was defective, the people were dirty and ignorant; they did not realize their danger from infection, and if they did they knew not how to prevent it. Those who were erecting these large tenements cared only for money; they cared not if the people did die, if only the rent was paid.

Dr. Janeway made a few closing remarks. He said that in Berlin the owner of a lot was not allowed to erect a building which covered more than two-thirds of the ground area.

The Necessity of Perfect Vision in the Education of the Young.—Dr. Frank Van Fleet read the paper. He thought it was admitted that asthenopia existed only among men, lower animals being free from it, and that it was more common among civilized than uncivilized people. The paper was intended to impress upon general practitioners the necessity for correcting weak or imperfect sight wherever it was possible to do so by glasses. Several cases were related in which neglect to do this had threatened the future prospects of the subjects, who had found that, for some unknown reason, they were unable to continue their studies, had been considered dull or lazy, and suffered the displeasure of parent and teachers. More than one had said, on receiving glasses, that a new world had been opened to view.

The paper was discussed by Drs. Hepburn, Cocks, and Bates. Dr. Hepburn said that horses sometimes suffered from imperfect vision, as he had once proven by experiments. Those accustomed to "shy" almost constantly and without apparent reason, had ceased to do so when fitted with glasses.

Dr. Anderson presented a small surgical cabinet, intended ever to be ready for transporting surgical instruments, antiseptic fluids, etc., to the patient's house.

AMERICAN PUBLIC HEALTH ASSOCIATION IN CONJUNCTION WITH THE INTERNATIONAL CONGRESS OF PUBLIC HEALTH.

Twenty first Annual Meeting, Held in Chicago, Ill., October 10, 11, 12, 13, and 14, 1893.

First Day, Tuesday, October 10th—Morning Session.

The Congress convened in Hall 7 of the Memorial Art Palace, and was called to order by the President of the World's Congress Auxiliary, the Hon. Charles C. Bonney, of Chicago, at 10.30 A.M.

Prayer was offered by the Rev. Dr. Parsons, after which addresses were delivered by Hon. C. C. Bonney, Mrs. Charles Henrotin, Dr. A. R. Reynolds, Commissioner of Health of Chicago, representing the Mayor, Dr. E. Liceaga, of Mexico, and Dr. Sarah H. Stevenson, of Chicago.

President's Address.—Mr. Bonney then introduced Dr. S. H. Durgin, of Boston, President of the American Public Health Association, as President of the Congress, who replied briefly to the several addresses, after which he delivered his Inaugural Address. He dealt with matters pertaining generally to the public health. He said the great trust which the Association took upon itself twenty one years ago has been worthily held, and the work to which it has addressed itself in the interest of humanity has been diligently pursued. It is fitting, perhaps, at this time, when we may be said to have attained our majority in years, to take a retrospective glance of public sanitation, and to note the possible results of its application in the relief of human distress. The work of the sanitarian is manifold, and deals with the most vital of our personal and social interests. It deals with the air we breathe, the food we eat, the water we drink, and with the general welfare of mankind. It means the investigation of the rise, progress, and decline of epidemics, and a fostering growth of works and projects designed to prevent and remove the causes of disease.

The sanitarian concerns himself but little with the cure of disease. The problem which he seeks to solve is how disease can be averted. The pathologist establishes the nature of morbid processes, and his investigations suggest to us the appropriate remedy. The aim of the sanitarian is to seek out and remove the cause or causes which produced these processes. It has been said that preventive medicine embraces everything which relates to the physical well-being of our fellow-men, so that it has to deal with all physical evils and, incidentally, many of a moral character. Its object is the health, and therefore the happiness and prosperity, of man.

In the city of Boston our private drainage, like that in most cities, is unsatisfactory, and the cause of an immense amount of inspection, complaint, and annoyance, and undoubtedly the cause of much ill health. We have statute laws and city ordinances which specify the method, material, and workmanship necessary for the construction of house drainage. Plans for construction and repairs are submitted to, and the work approved by, the inspector of buildings.

The Board of Health is called upon to find defects and to order repairs, and such repairs each year number about four thousand five hundred. For the purpose of ascertaining to what extent defective conditions of plumbing exist, and to what extent traps are supplied, and water-closets substituted for privy vaults, we have taken a large number of blocks of dwellings, both new and old, each season for thirteen years, and made house-to-house inspection.

It is a common thing to find on death certificates, instead of the morbid process which caused death, such indefinite information as "disease of bowels," "disease of brain," "disease of skin," "stomach disease," "ascites," "convulsions," "dropsy," "fever," "debility," "teething," "inflammation," "infantile," "heart failure," and other unlikely causes too numerous to mention, and which ought never to be used upon the records as causes of death. In his own city, such certificates are rejected, and a competent physician sent to view the remains, and consult the family or friends of the deceased for information, with which to make a proper certificate. It is to be noted, however, that information gathered in this way cannot be regarded as wholly trustworthy, and often results in the statement of "unknown cause of death."

The mention of cholera, like that of smallpox, strikes terror to the people of this country, and while the deaths from these diseases are infinitely small, the fear of them has served the municipal health officers in securing almost unlimited facilities for their prevention and control, which means may be largely converted to the care of other more common and destructive contagious diseases.

Consumption, the most destructive malady to the human race in our country, has received the necessary attention of the bacteriologist. He has demonstrated to us, satisfactorily, the cause of the disease, the methods of its transmission, and the means for its prevention. He is sorry to say that, as practical workers in public sanitation, we have sadly neglected to apply the means which we believe would prove effectual in largely abating the prevalence of tuberculosis. The isolation of all persons suffering from consumption would be impracticable and perhaps unnecessary, but the use of small sputa cups containing a disinfectant, at home, and bits of absorbent napkin used and securely concealed in travelling, to be burned or otherwise disinfected on returning, should at least be urged by public health officers, and popularized as much as possible.

Turning, in conclusion, from the more onerous every-day duties of the municipal health officer to topics of greater popular interest, we find an increasing growth of public sentiment, in all parts of the country, favoring the municipal provision of large public parks, free public baths, small open spaces, and open-air gymnasiums for

the enjoyment and sanitary welfare of the masses of people whose whole time is spent in the toil of our large towns and cities.

The General Committee of the World's Congress Auxiliary on a Public Health Congress, consisted of Dr. John H. Rauch, *Chairman;* Dr. F. W. Reilly, *Vice-Chairman;* Dr. F. W. Brewer and Dr. C. N. Hewitt, *Joint Secretaries;* Dr. E. Garrott, Dr. J. M. Hall, Dr. John B. Hamilton, Dr. Liston H. Montgomery, Dr. S. J. Jones, Dr. A. R. Reynolds, and Dr. B. J. D. Irwin.

After some announcements by Dr. Brewer, the Congress adjourned until Wednesday morning.

SECOND DAY, WEDNESDAY, OCTOBER 11TH—MORNING SESSION.

The Congress was called to order at 10 A.M. by the President.

Sanitary and Medical Service on Emigrant Ships.—The first paper read was by Dr. ALBERT H. GIHON, Medical Director of the United States Navy, with this title.

Report of the Committee on Restriction and Prevention of Tuberculosis.—This report was read by the Chairman of the Committee, DR. J. N. MCCORMACK, of Bowling Green, Ky. The Committee offered as its report the following conclusions and recommendations:

1. Tuberculosis has been conclusively demonstrated to be contagious, by bacteriological experiments, by clinical observations, and by a study of the history of the disease.

2. Tuberculosis is a preventable disease. Its preventability follows as a logical sequence upon its contagiousness, but has likewise been demonstrated in practical life.

3. The contagium of tuberculosis resides entirely and solely in broken-down tubercular tissue. A person suffering from tuberculosis, therefore, does not become a source of danger to others until he begins to give off broken-down tubercular tissue, either in the form of sputa from the throat or lungs, diarrhœal discharges from the bowels, or matter from a tuberculous sore such as lupus, white swelling, cold abscess, scrofula, or tubercular inflammation of a joint.

4. A person suffering from tuberculosis can be made entirely harmless to those about him by thorough sterilization of all broken-down tissue immediately upon its being given off. With proper precautions, it is therefore possible to live in the closest relation, and upon the most intimate terms, with consumptives without contracting the disease.

5. Tuberculosis is not hereditary. A predisposition to the disease can be transmitted from parent to offspring, but this is more true of tuberculosis than it is of all other contagious diseases.

6. A predisposition to tuberculosis can be created anew by malnutrition or by anything which depresses the nervous system.

7. Tuberculosis affects animals as well as man, and is identically the same disease in both. In domestic life human beings and animals mutually infect each other.

8. The media through which human beings are ordinarily infected by animals are milk and meat.

9. Houses in which consumptives have lived, and in which immediate sterilization of all broken-down tissue has not been practised, are infected houses, and are liable to convey the disease to subsequent occupants.

10. Spitting upon floors and into handkerchiefs, and permitting the broken-down tissue to dry and become pulverized, is a prolific cause of spreading tuberculosis.

11. Temporary occupation of hotel rooms, sleeping-car berths, and steamer cabins by consumptives in the infectious stage, can infect them so as to convey the disease to subsequent occupants, unless proper precautions are taken against contamination of the bedding, furniture, and walls with broken-down tubercular tissue.

We recommend the following practical measures for the prevention of the disease:

1. The notification and registration by health authorities of all cases of tuberculosis which have arrived at the infectious stage.

2. The thorough disinfection of all houses in which tuberculosis has occurred, and the recording of such action in an open record.

3. The establishment of special hospitals for the prevention of tuberculosis.

4. The organization of societies for the prevention of tuberculosis.

5. Government inspection of dairies and slaughter-houses, and the extermination of tuberculosis among dairy cattle.

6. Appropriate legislation against spitting into places where the sputum is liable to infect others, and against the sale or donation of objects which have been in use by consumptives unless they have been thoroughly disinfected.

7. Compulsory disinfection of hotel rooms, sleeping-car berths, and steamer cabins which have been occupied by consumptives, before other persons are allowed to occupy them.

The reports and recommendations of the Committee were adopted.

Tropical Diarrhœa.—This paper was contributed by SIR JOSEPH FAYRER, of London, England, and read by DR. GIHON. This is a form of disease which is generally, if not always, the result of tropical and climatic influences, and the debility and cachexia induced thereby. It is now not infrequently observed in Europe, owing to the ever-increasing means of communication with foreign countries. It is apparently generally confined to adults, is insidious in its onset, slow in progress, and often, when not arrested sufficiently soon, fatal, owing to irreparable degenerative changes. It has been described by many observers, both English and foreign, in India, China and Cochin China, and Batavia. Most of the cases seen in this country come from China, India, or Ceylon. In India it is met with frequently, where a form of it is known as "hill diarrhœa," from its proneness to affect dwellers in hill stations, especially those who have previously lived in the plains; atmospheric changes, vicissitudes of temperature, greater altitude, rarefied atmosphere, and possibly water, being concerned in its causation. Some authors consider it a distinct disease from the white flux which may be seen in any part of the country, but they are so much alike as to justify the belief in their identity, at all events for practical purposes. Occasionally there is a resemblance to certain forms of chronic dysentery; the two conditions may be associated, or one may merge into the other.

Tropical diarrhœa occasionally makes its appearance years after the subject of it has returned from the tropics. It not infrequently begins without any previous apparent derangement of health, though it is sometimes preceded by dysentery, diarrhœa, some indication of malarial infection, or functional derangement of the liver or other abdominal viscera, and is not noticed until excessive soreness of the tongue and loss of strength and wasting reveal the gravity of the condition.

Semeiology.—This form of diarrhœa may begin with simple looseness of the bowels, or may supervene on ordinary diarrhœa or chronic dysentery. The action produces a sense of relief. The dejecta at first may be natural and bilious, but gradually become light colored, frothy, pultaceous, and copious. As the disease advances they are occasionally tinged with blood, and the sufferer becomes more attenuated, exhausted, and incapable of any prolonged exertion. The appetite may be good, but rawness and tenderness of the mouth and tongue, frequently accompanied by aphthous spots and ulcerations, interfere with its gratification.

Treatment.—From the insidious character of the disease, tropical diarrhœa not infrequently gains ground before radical measures for its relief are resorted to. Suc-

cessful issue depends much on the patient's resolution and perseverance in carrying out instructions. Alternations of temperature, errors of diet, fatigue or excitement, exertion, mental or physical, should be avoided. Physiological rest should be insisted on.

There is a tendency in the earlier stages to get well. The object is to favor this tendency, and not thwart it by neglect of precautions. Diet is the most important consideration, and must be strictly regulated and adhered to; and scarcely less important is the question of clothing, habits, and mode of life.

Milk alone should be the only diet, and it must be given in small quantities often repeated, say from four to six ounces every hour, day and night. Larger quantities at longer intervals will not do. When in the twenty-four hours an adult is able to take three to four quarts of cow's milk in this way, ample nourishment is afforded to support his strength and to enable him to recover.

This method of treatment was begun by the author before leaving India in 1872. After prolonged experience and trial of all other forms of remedies, he has found it more effective than anything. It seldom fails except in the very advanced and chronic cases, or in very aged persons. The conclusion arrived at is that, though drugs are generally of little avail, if milk, taken as prescribed, does not succeed, there is but small chance that any other form of treatment will do so.

Cholera Infantum and its Treatment, by Dr. Manuel Septién, of Queretaro, Mexico. The treatment proposed is exceedingly efficacious. It consists in the total suppression of all food and medicine during twenty-four or forty-eight hours, and the prescription of pure cold water in great abundance. The author said there is scarcely any disease that causes a greater mortality in childhood than that known by the name of estival diarrhœa or infantile cholera. In one single week, the last one of July of the present year, there were one thousand one hundred and twenty-six deaths in thirty-three of the largest cities of England, caused by this disease alone. Statistics show everywhere a notable increase in the number of deaths during the months of June, July, and August, that is to say, during the warmest season of the year. The malady is not limited to children only, but attacks also a great number of adults and old people, being less mortiferous in the latter than in the former, in whom it causes a mortality of fifty, sixty, and even eighty per cent. Only Asiatic cholera, to which it has the greatest similarity, can be compared to it for its ravages. It is undoubtedly of microbic origin, as recent investigations have shown.

Energetic drainage is the supreme effort which nature executes to rid the organism of the deleterious elements that poison it. To try to suppress it by therapeutical means is not an easy or rational thing to do. It would only hinder the natural curative process. The only thing that can be done is to oppose the extreme dehydration of the tissues by restoring to them without delay at least a part of the water lost. This is the therapeutical indication, and no drug can take its place, nothing but pure cold water.

All the curative methods tried leave much to be desired. Their results are very precarious; all consist in the administration of various medicinal substances, astringents, absorbents, antiseptics or antiperistaltics, and in the prescription of some alimental regimen. Such treatments, according to the author, are not in conformity with the great principle that governs therapeutics, namely, the rest of the organ that suffers.

The author had practised successfully the treatment recommended by Luton, of Reims. He summarized the points of his paper as follows: 1, To suppress all nourishment and medicine for one or two days; 2, to give at discretion pure cold water; 3, to return by degrees to a rational regimen.

Origin and Dissemination of Typhoid Fever, by Professor W. T. Sedgwick, of Boston. Professor Sedgwick's remarks on this subject were impromptu. He first dwelt upon the reorganization of the State Board of Health in Massachusetts in 1886, shortly after which an experiment station was established at Lawrence for the purpose of studying typhoid fever chemically and bacteriologically, looking to the purification of the water. In 1890 an epidemic of typhoid fever broke out upon the Merrimac River, in the city of Lowell, and shortly afterward appeared at Lawrence, nine miles below. These epidemics afforded unusual opportunities for the investigation of the epidemiology of typhoid fever.

Afternoon Session.

Sewage Disposal.—Mr. Allen Hazen, of Lawrence, Mass., read a paper entitled "The Sewage Disposal Problem in American Cities." He said one of the striking features of the sanitary development of American cities is the very rapidly increasing number of places which, for one reason or another, are treating in some way their sewage. It is not so very many years since there was hardly a sewage purification plant in the United States, while at the present time there are some thirty municipalities, in a dozen different States, which give their sewage a more or less thorough treatment. Of these a number are in the far West, where the sewage has a commercial value for irrigation which has probably been considered quite as important as the sanitary advantages secured by the treatment; but the greater number are in the East, where a dense population and increasing desire for cleanliness in the waters of streams and lakes, and particularly in water-supplies, has brought to an issue problems which as yet have scarcely received the attention of the inhabitants of the less thoroughly settled States.

There are two sewage problems which are entirely different in their nature, although the same remedies may often be applied to both. There is first the pollution of rivers and lakes to such an extent that they produce a nuisance to the people who live upon their banks, and secondly the pollution of water-supplies by sewage. The first case is often that of a city upon the banks of a small river which becomes so reduced in volume in dry weather that the sewage may fairly be said to be the predominating element in its composition. Up to a certain point, rivers are capable of taking sewage without causing a serious nuisance to the people who live upon their banks, so long as they do not drink from them; but when this quantity has passed, deposits are formed, decomposition sets in, and the stream is rendered foul in appearance and objectionable in its odor. The exact quantity of sewage which can be mixed with water without causing a nuisance, varies with local conditions, and can only be approximately estimated, but as long as the limit is not passed, and the water is not used for drinking, the disposal of sewage by turning it into such water is entirely unobjectionable, and by far the most satisfactory method possible.

Where the sewage of a town is entering the public water-supply of a neighboring town, or worse yet, its own supply, the problem is entirely different. The removal of the organic matters of the sewage becomes a secondary, though still an important matter, while the removal of those germs of disease, which would otherwise work such mischief among the consumers of water, becomes the one important point.

The experiments undertaken by the Massachusetts State Board of Health at the Lawrence Experiment Station, some six years ago, indicated that the local conditions in Massachusetts would allow the treatment of sewage upon land even with more favorable results, both as to quantity of sewage treated, and quality of effluent obtained, than had been supposed to be the case from a study of European practice.

It is impossible, by any combination of chemicals, to secure a purification which approaches, even remotely, the result obtained by land treatment; but when the problem is simply to keep the water into which the sewage flows reasonably clean, the result, with careful manipulation, is quite satisfactory. When, however, the treated

sewage finds its way into the source of the public water-supply, the effluent produced by even the most complete chemical precipitation cannot be regarded as an entirely unobjectionable addition, and such water should be further treated by filtration before use.

The Collection and Disposition of Animal and Vegetable Waste in the City of Milwaukee, by Dr. U. O. B. Wingate, Commissioner of Health of Milwaukee. As early as 1879 the city of Milwaukee began to grapple with the garbage problem, and it has been a long and serious struggle until a recent date. In the winter of 1891–92 the State Legislature passed an act authorizing the Common Council of the city to enter into a contract for the disposition of garbage, with the advice of the Mayor and the Commissioner of Health. It was decided to let the contract for five years to a company who would build a plant fourteen miles out of the city, collect and remove to said plant all garbage, offal, dead animals, both great and small, and animal matter of the city of Milwaukee, including refuse matter from commission houses, etc., to said plant, in which they would dispose of it in a sanitary manner. This contract went into effect and the work was commenced in June, 1892.

The company constructed a plant at an expense of some $110,000. They purchased a powerful steam barge for transportation; they put on fifty steel, air-tight wagon tanks for collection, and two large covered wagons for the collection of large dead animals. Since September 1, 1892, the plant has been in operation to the satisfaction of the city officials of Milwaukee, creating no nuisance or stench whatever that can be reasonably objected to in its location, and the collection and transportation of the material during that time has been fairly satisfactory.

Disposal of Garbage and Waste of World's Columbian Exposition, by Col. W. F. Morse, of New York. Since the meeting of the American Public Health Association, two years since, marked progress has been made in the destruction of garbage and waste of cities by fire. Six years' experience has shown this method to be of far greater value than any other, and improvements in furnaces and reduction in cost of operation have steadily made it more popular and useful.

England has now furnaces in every large city and the number is yearly increasing. This country is awakening to the value of this method, and it has been inspected and recommended at a great number of places. The most striking and effective work done in the world is at the World's Fair, where two furnaces of the Engle Sanitary Company have been at work since the first of May.

It was early seen that the sanitation of the Fair, the care of the health of the great multitudes resident and who would come as temporary guests, would demand the best, and only those which had been thoroughly tested, methods of providing for the drainage, and the collection and disposal of the great mass of daily accumulating garbage and organic waste. After the drainage was arranged the question of sewerage disposal and garbage destruction came up. A contract was made with the Engle Sanitary Company of Des Moines and New York, for two garbage cremators to burn one hundred tons of sewerage sludge, garbage, and stable refuse. These two furnaces were built in the fall, and at the opening of the Fair were ready for work. They are in the extreme southeastern part of the grounds, near the Forestry Building, back of the power-house of the Intramural Railroad, employing the well-known device of the Engle Company—two fires, one at either end, the one burning the mass of garbage on the grates, the other destroying the smoke, gases, and all results of this combustion. These furnaces have been in constant work every day since May 5th. The garbage is brought at night, from 11 to 8 o'clock, A.M., and placed at once in the furnaces. From twenty-five to forty loads, each of one ton, having sometimes ashes or water in large amounts mixed therewith. Everything goes into the furnaces: four horses, two camels, cows, deer, elk, pigs, goats, dogs, etc., all follow the same road and are burned with equal ease. No results can be seen from the chimney. A thin, invisible carbonic acid gas, discharged at a temperature of 1,000 degrees, is all that results. No smoke, no odors, nothing that can be offensive is detected. Though in daily use, an observer would not know any work was done, unless he came to the building. At 10 A.M. the loads of sewerage cake begin to come. This is a thick, heavy, soggy mass of lime, fecal matter, paper pulp, etc., with sixty per cent. of water mixed. The quantity varies from ten to eighteen or twenty five tons, and is the most refractory material to burn yet found. The fires are oil-fed by jets of air, a pressure of twelve ounces of air doing the same work that is done in the boiler-house with one hundred and twenty pounds of steam. The ashes are used by Exposition people for filling low places, though they have a value of $10 per ton for fertilizers. There are six burners spraying oil, the whole using thirty-seven and one-half gallons per hour. The cost for fuel and labor is from 75 to 85 cents per ton for sewerage sludge, and 50 to 70 cents for garbage.

At other places where these same furnaces are used the cost is reduced by bringing to the furnaces the paper, sweepings, and all kinds of city combustible waste, which makes fuel to burn wet matter and reduces the cost 12 to 15 cents per cubic yard, or 30 to 40 cents per ton.

Official reports from Savannah were read, showing the cost for last eight months to be 11 cents per cubic yard. The work has been continuous, no stoppage, no nuisance, performed under observation of thousands of persons, inspected by many interested in this work from abroad, and has met with deserved credit and favor from the Board of Administration.

By adoption of similar furnaces at four points in Chicago, the whole garbage nuisance could be abolished, the same work done for the city that is here performed, at a reduced cost, and the vexed problem of garbage disposal settled and got rid of once for all. This is no theory or experiment. This company was asked to do this work because they had demonstrated elsewhere their ability. There are forty furnaces or more built by the Engle Company and in successful operation; more than twenty times as many as have been built by others; but this is the most successful instance of the destruction of garbage on a large scale that has been seen in this country.

How Can Women Promote Public Sanitation?—by Dr. Sarah H. Brayton, of Evanston, Ill. She said, as instructors in hygiene nurses have a wider scope for sanitary reform than physicians, living as they do with the families they attend their opportunity for the diffusion of knowledge is greater. Undoubtedly there is much that women could do on health boards, there is more that they must do among their own sex to increase the sum of sanitary knowledge among all classes and promote intelligent co-operation with health authorities, whoever they may be.

The Progress of Sanitary Knowledge among the Women of England.—This was the title of a paper contributed by Lady Priestley, of England, and was read by Mrs. Henry Wade Rogers, of Evanston. The author of the paper went back twenty years, when she first jointed the Executive Committee of the National Health Society, and attended the meetings in a small, dingy, draughty room in a house about as unsanitary as any to be found in London, and traced the progress made in sanitary science from that time to the present. The author would impress upon all mothers, and those who are responsible for the welfare of others, the desirability of giving personal care and forethought, which alone can avert the consequences of unsanitary surroundings.

Notes on Cholera and its Management in Hull, England.—This was the title of a paper contributed by Dr. John Wright Mason, Medical Officer of Health in Hull, but was read by Dr. Charles N. Hewitt, of Minnesota, in the absence of the author. The first epidemic of cholera occurred in 1832, but the total number of deaths from the disease did not exceed two hundred and seventy. On August 10, 1849, the great visitation of

the disease commenced. The total number of cholera and diarrhœa victims during the invasion was 1,860, being one in forty-three of the whole population of eleven thousand. Six hundred persons died from cholera alone in one week in September. The average age of the victims was from thirty to thirty-six. Of the total number of deaths recorded, seventeen hundred and thirty-eight belonged to the laboring classes, and one hundred and twenty two to the wealthy. The greatest mortality occurred in those parts of the town where the levels were the lowest, and in which the unsanitary surroundings were the most noticeable. It is recorded by an eminent minister that on one day—black Sunday—he himself interred no less than forty-three bodies of his fellow-citizens. The water-supply was at that time obtained from the stone-ferry waterworks, situated one and a half mile from Hull and two and a half miles from the mouth of the river, the water being obtained from the River Hull, the widespread character of the epidemic being greatly attributed to the impurity of the river water. Since 1849 Hull has increased both in wealth and population, and its area has been considerably extended. The number of emigrants passing through the port *en route* for America has averaged between fifty thousand and sixty thousand yearly during the past ten years. The Infectious Diseases (Notification) Act, 1889, has been applied to the port as well as to the urban authority. Measles was included among the notifiable diseases on February 10, 1893.

Cholera follows the line of international communication, and with the modern increased facilities for rapidity of transit, so is the danger of its possible invasion increased by emigration or otherwise. England does not depend upon the false security of quarantine, but rather upon its sanitary administrations, and each district should be in such a state of sanitary preparedness that the disease, if imported, should not spread. The experience of 1892, during the epidemic at Hamburg, in those ports which were exposed, and possibly none more so than the port of Hull, which was in daily communication with that cholera-stricken city, must have inspired confidence in the public mind in this country and the continent of Europe that medical inspection, the due regard for the rigorous inspection of all articles likely to convey infection, improved sanitation, and efficient hospital equipment, were alone sufficient to arrest the progress of the disease. Our first line of defence against the introduction of cholera consists of the medical inspection upon arrival, both by day and night, of all vessels from cholera infected or suspected ports, and should cholera have developed during the voyage among any of the passengers or crew, the removal of the patients to hospital and the isolation of suspected cases, and the detention on board the vessel of such persons who may be in a filthy or otherwise unwholesome condition, and who cannot satisfy the medical officer of health as to their place of destination.

The second line of defence against the possible introduction of cholera, or other diseases, should be well protected, and the early preparations against the means by which such diseases, if imported, spread, should be studied, thought out, and perfected in the interim, and not during epidemic prevalence and excitement. Special attention should be directed toward a pure and unpolluted water-supply, the periodical and regular removal of all excreta and refuse matters in the midst of populations, the frequent flushing of all drains and sewers, the prevention of overcrowding, the systematic inspection of common lodging-houses, and lastly, but not least, our food-supplies.

Hull is essentially a privy town. The death-rate of Hull from all causes, for the ten years 1882 to 1891, averaged 20.7 per thousand. The death-rate from fevers during the same period was equal to 1.26 per thousand, and for diarrhœa alone 1.10 per thousand.

The author then dwelt upon the management of cholera. The precautions which are adopted in Hull of what has been described as "the movement of a sanitary column," are as follows:

Immediately upon the receipt of a notification of cholera, or of sudden illness of a choleraic character, either by the medical practitioner in attendance, the sanitary inspectors, or the police, the medical officer of health is communicated with and immediately visits the case, or in his absence his assistant. Should the case admit of removal, the horse ambulance, fully equipped with trained men in attendance, is immediately requisitioned by telephone. The assistant inspector of nuisances for the district in which the case occurs, is forthwith acquainted, and makes his appearance with a column comprising flushers, lime-washers, and disinfecting staff. He superintends the removal of the inmates of the house to hospital for the purpose of bathing and the disinfection of their clothing, the disinfection of the house, together with all articles of bedding, clothing, etc., which have been exposed to infection, and the destruction of such articles as may be ordered by the medical officer of health or his assistant. The contents of the privy are removed to the destructor for cremation and the interior cleansed, disinfected, and lime-washed. The subsidiary drains in the immediate contiguity of the house are thoroughly flushed, and disinfectants are freely distributed in the neighborhood of the outbreak.

(To be continued.)

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

OPENING OF THE SCHOOLS—LORD THRING AT ST. THOMAS'S HOSPITAL—SECRETS OF SUCCESS—PRESENTATION TO DR. BRISTOWE—DR. LIONEL BEALE, F.R.S., ON PROGRESS AT KING'S COLLEGE, AND ON THE NATURE OF LIFE—THE NEW SESSION AT THE MEDICAL SOCIETIES—PLACENTAL HEMORRHAGE—INFLUENCE OF SEASONS AND WEATHER ON PUERPERAL FEVER—STATISTICS OF LYING-IN HOSPITALS—TYPHOID FEVER—WEST LONDON SOCIETY—CLINICAL SOCIETY—NOTIFICATION OF INFECTIOUS DISEASES—DEFECTS OF METHODS—INSUFFICIENCY OF HOSPITAL ACCOMMODATION—NEGLECT OF OBVIOUS PRECAUTIONS AT A HOSPITAL.

London, October 7, 1893.

All our schools are now at work, the great October festival for the year having gone off with its customary *éclat*. At St. Thomas's Hospital Lord Thring distributed the prizes and delivered a sympathetic address on the occasion. He was particularly happy in his allusion to the hard work and scanty pay of the rural practitioners, and pronounced it one of the glories of the great profession, which sent into the remotest districts worthy members, who cast a bright light over the dark abodes of misery, and deserved more than any other class the affection of the poor and miserable. To the students he said he could not offer them professional advice, but he could urge them to diligence and perseverance in their important studies. For success in life he declared that what was the first necessity was perseverance, the second was perseverance, and the third was also perseverance. Another secret was to be always ready, watching and hoping for opportunity.

Then followed an interesting ceremony—the presentation to Dr. Bristowe of his portrait, which had been painted by his daughter and exhibited at the Royal Academy this year. Old students and colleagues purchased the portrait from the artist and presented it to her father. The balance—for there was a balance—of the subscriptions is to be devoted to a medal for proficiency in pathology.

King's College is often called sectarian and narrow, just as its rival is called godless. Lionel Beale is Professor of Medicine at King's, and to him this year the introductory lecture was intrusted. Your readers are acquainted with his writings and will be prepared to learn that he gave a good account of progress in this

school, and put in an excellent defence of the orthodox view of the nature of life. Many questionable assumptions have been dealt with by Dr. Beale in his work on protoplasm, and now he pointed out that it is mere assumption to suppose that because we know more about matter and force, we also know more about life. Dr. Beale sees nothing in science to prevent the Christian looking back in the past for unchanged and unchanging perfection, although Mr. Huxley asserts that the "ecclesiastical spirit . . . that clericalism is the deadly enemy of science." Dr. Beale thinks Mr. Huxley will have no supporter among scientific men in this contention, and that to bring such a charge in these days is ridiculous and like beating the air. The assertion that the formation of every living thing "is a purely mechanical problem" the lecturer pronounced to be devoid of all foundation. "The machine which we call the body," said he, "is not a machine, for the human body has grown and must die, while the machine is made, but has never lived and cannot die." Mr. Huxley's lecture at Oxford, when he told the story of Jack and the Beanstalk, and remarked that the plant building itself up and then withering might "be likened to the ascent and descent of a slung stone, or to the course of an arrow," was then answered by Dr. Beale to the effect that the comparison suggests that the stone slings itself and the arrow shoots itself. And this, he continued, "is the physical consummation of all things from the first to the last, and we may hope it will be the last of such shadowy vaporings, which emanate from cosmic vapor, are nowhere, and lead to—nothing." In Mr. Huxley's late lecture it is said that "natural knowledge tends more and more to the conclusion that all the choir of Heaven and furniture of the earth are the transitory forms of parcels of cosmic substance wending along the road of evolution from nebulous potentiality . . . back to the indefinable latency from which they arose." This statement was traversed by Dr. Beale, who asserted his conviction that in all science no justification for such a conjecture is obtainable, and that there is no evidence whatever that "natural knowledge tends," as asserted, or ever did tend, or ever will tend to the conclusion that life has anything to do with "nebulous potentiality," or "indefinable latency," but Dr. Beale slyly added the admission that we may agree that whatever has really come from "nebulous potentiality" will no doubt "wend its way to indefinable latency." There are many other points in Dr. Beale's introductory which make it worthy of careful reading. He concluded as follows: "If we allow ourselves to be influenced by facts and reason, we must conclude that life is not a property of matter, that the living world and the non-living world are distinct, and that the former is not a natural outcome of the latter; that if all living things were destroyed, the matter of their bodies and the matter of the non living world would remain indestructible, but would also remain incapable of giving rise to new life; and that up to this day it has not been shown that fundamental religious beliefs have been shaken, destroyed, or rendered untenable by the wonderful truths which have been established by the unprecedented progress of scientific discovery in every department of natural knowledge during our time."

London, October 14, 1893.

Teachers and students have now settled down to the regular work of the session. Even freshmen are finding their way about, and their seniors are, of course, perfectly familiar with the routine of the schools. The societies have also reopened, and there is a goodly bill of fare at several.

At the Obstetrical Society, on the 4th, a case of placental hemorrhage was related and some interesting remarks followed. The patient, aged nineteen, was frightened by a rat, and a subsequent speaker said that a fright by a mouse or rat, of which women are unaccountably afraid, is a common cause of the accident. In this case Dr. Muir said there was a recurrence within two weeks, and therefore premature labor was induced by Dr. Griffith. On examining the placenta indications of the two hemorrhages were found, the older involving two-fifths and the other one-fifth of the mass. Obviously any further hemorrhage would have been fatal to the fœtus; so, as the patient would not consent to remain in the hospital, Dr. Griffiths operated. Dr. Hayes supported the practice in recurrent hemorrhage not due to placenta prævia.

The relation of external meteorological conditions to the incidence of febrile diseases in childbed was the subject of a paper by Dr. Boxall, which is a sequel to a former paper of his. Statistics of mortality were submitted from the Registrar-General's returns for London and Professor Lusk's table for New York, showing the death-rate from puerperal fever to be higher in winter than summer. This is also the case as to morbidity according to the statistics he submitted from the records of the General Lying-in Hospital. On the other hand, septic illness, though more prevalent, is less severe in winter than in summer. Dr. Hayes was sceptical of general statistics and deprecated any suggestion that the occurrence of these febrile attacks might not be entirely the fault of the practitioner or the nurse. Dr. Champneys thought it possible that the lack of ventilation in winter might account for the facts. Dr. A. Routh remarked that people were less inclined to wash their hands in cold weather, and suggested that, like birds, beasts, and fishes, women might arrange to bring forth in summer only. The President (Dr. Herman) said the main conclusion cannot be disputed, and is confirmed by Dr. Minor's observations on erysipelas in the puerperium. Though infective agents may be many, he said all are amenable to cleanliness and antiseptics. In his reply Dr. Boxall said his object was to show that meteorological conditions had little or no direct influence on the incidence of septic illness. The winter months were the time of greater want and exposure among the poor, and the differences he had shown in general practice were scarcely perceptible in hospitals, showing that the influence of season must be indirect.

The President of the West London Society related his experience of typhoid fever, derived from one hundred and sixteen cases in ten years, with a mortality under ten per cent. He deprecated the extreme antipyretic treatment, and held that the low mortality of relapsing fever, in which the temperature often runs to 107° F., shows that pyrexia *per se* is not necessarily of grave omen, though pyrexia plus the disease which causes it may be so. Thus in acute rheumatism a high temperature might be an appalling danger, while in influenza, ague, or relapsing fever, it might be of slight moment. He supported the use of alcohol in typhoid and strongly deprecated the use of aperients during the entire period of the disease.

The programme at the Clinical Society last night was the Presidential address; a paper by Mr. Mayo Robson, on "Dilatation of the Stomach with Severe Pain Dependent on Pyloric Adhesions, Treated by Abdominal Section and Separation of the Abnormal Attachments;" "Two Cases of Excision of Malignant Tumor from the Large Intestine," by Mr. W. Edmunds; "A Case of Gastrojejunostomy," by Mr. L. A. Bidwell.

The methods of notification of infectious disease are certainly very imperfect, and some able persons still oppose this plan of restricting their spread, as they believe that we can never achieve an ideal success. Some rather awkward illustrations of the difficulties in which we are involved by existing legislatives have lately found their way into the newspapers, where, of course, any mistake of a professional man is sure to draw the small wits of some journalist or other. In spite of the sincere effort of the majority of medical men to act up to the directions of the present law, several of our brethren have been called to account for slips and have been fined for neglecting to notify. I am sorry to say that in some instances medical officers of health have not shown that courtesy to prac-

titioners which is expected of professional brethren, who ought at least to be gentlemen. Friction must ensue when the sanitary authorities are devoid of tact or even deficient in that important qualification for public work.

In consequence of the spread of infectious diseases the Asylums Board has had all its hospitals full, and some painful cases have occurred of the patient being taken from one place to another, and to a third, without finding a vacant bed. Some of the general hospitals, too, have had their fever wards fully occupied by cases developed in other wards.

We fine a cabman who neglects to disinfect his vehicle as occasion requires, we fine the persons who neglect to notify a case of infectious disease, some sanitary authorities are such zealots that they insist on every medical man who sees a case notifying the same, and so compelling even consultants, when called in, to send an additional notification. But it seems impossible to provide against every event. Here is a case that came within my knowledge last week in one of our large hospitals with an excellent medical school. A student contracted scarlet fever; the house physician looked after him and, I dare say, other members of the staff gave advice; a nurse was procured from outside to watch the case and was expected to go home at night to sleep, and it was proposed to call in another to take the night work and go home to rest by day. These nurses were, of course, liable to a fine for walking through the streets after exposure to infection, and if their families had contracted the disease the cases would have been notified, and probably the hospital authorities and others concerned would have discovered the danger of thus boldly setting at naught the Act of Parliament. Even had there been no question of law I find it difficult to understand how, in the centre of a flourishing medical school where the antiseptic cult is fully carried out, the most ordinary precautions should thus have been neglected. Even prior to the Notification Act such obvious danger of spreading scarlet fever would have been recognized and avoided.

CEREBRAL ANÆMIA AND PUERPERAL ECLAMPSIA.

To the Editor of the Medical Record.

Sir: In the excellent report of the Canada Medical Association which appeared in your issue of the 14th inst. I am made to say I doubted that the brain was anæmic in puerperal eclampsia, and that I thought that the brain was congested. As I hold very strong views on this subject, and as they have always been exactly the opposite to those credited to me in the report, kindly allow me to state what I did say, as may be seen in the stenographic report. I said that there was no room for doubt as to the convulsions being due to the presence of a poison, which was urea and nothing else, and that the urea accumulated in the blood because the kidneys failed to do their work of eliminating it. They failed to excrete urea because they were in a state of congestion or chronic inflammation, and for the same reason they allowed the albumin of the blood to pass through them. Some thought that the anæmia of the brain was the cause of convulsions, but it was rather a coincidence, the brain and every other organ being rendered anæmic by the albuminuria. The dropsy was merely the result of the poverty of the blood in albumin. In my opinion the cause of the whole trouble is pressure on the venous circulation of the kidneys, as it was much more frequent in primiparæ and still more so when they had twins or were otherwise rendered very distended. I was one of the first in this country to advocate the immediate lessening of this pressure by the rupture of the membranes, which in this case is much preferable to the slower methods of inducing premature labor. Some have maintained that this would bring on convulsions by reflex irritation, but even if it did it would not be so apt to do so as natural labor later on when the kidneys had become still more disorganized. In fact I have gone so far as to hold that it was our sacred duty to terminate every pregnancy as soon as we discovered that the urine was loaded with albumin, for if we allowed this state of affairs to go on too long the kidneys might become, as they frequently do, irretrievably injured I therefore heartily agreed with the management of the case by the reader of the paper, namely, the immediate rupture of the membranes and the administration of a drachm of chloral hydrate by enema for the purpose of relaxing the os and diminishing peripheral irritation. In my experience the albuminuria and dropsy began to diminish and the excretion of urea to increase immediately after the rupture of the membranes, although convulsions might still continue owing to the injury already done to the nerve-centres by having been bathed in poison for so long a time. Hoping that my great interest in this subject may be a sufficient excuse for this letter,

I am, etc.,

A. Lapthorn Smith, M.D.

Montreal, Canada.

THE INTERNAL ADMINISTRATION OF CALOMEL IN THE TREATMENT OF PSEUDO-MEMBRANOUS LARYNGITIS.

To the Editor of the Medical Record.

Sir: As I may be considered responsible for the perpetuation or reintroduction of the calomel treatment for pseudo-membranous laryngitis or diphtheria, by the publication of my essay on the subject[1] in 1886, I therefore derive much pleasure in reading the valuable contribution of Dr. S. Kohn, of New York, in your issue of August 19, 1893, and I desire to say that the calomel treatment has continued to hold its record with me for excellence since the publication to the profession of my brief essay. The period since then is over seven years, and as I had resorted to this plan of treatment for over ten years before I published my essay, certainly the method must have real merit, when it has not been abandoned by me in that long time, excepting occasionally to test some of the many other methods, which after a careful trial disappointed me and impelled me to return to this one.

The profession will have noted that since the appearance of my article the general exhibition of mercurials in this disease has been quite a common and rather efficient practice. I cannot but regard them all as modifications of the calomel treatment, without, however, the higher efficiency of the calomel; that is to say whatever good they have accomplished is by reason of the antiseptic action of the mercurial used, and as but few of them admit of so large doses as is permissible with calomel, therefore their antiseptic effect is not sufficiently strong locally, within their limits of safety, in the throat, where a youthful patient is liable to swallow a poisonous dose, for example, of the bichloride of mercury.

I have been much surprised and no little pleased with the wide dissemination of the ideas I reintroduced to the profession in my article in 1886, and the evidence I have received from the many sources of their adoption, both in America and Europe, and I am none the less pleased with the evidence advanced by Dr. Kohn, of New York, and with his independent arrival at such similar results to my own from the calomel method of treatment; in fact, I consider his arrival at such excellent and certainly similar results, although beginning the use of the remedy as he did about a year and a half after the publication of my essay to the profession, as none the less justly claimed by the doctor as being "the result of his own thought and experiment" and I make Dr. Kohn my sincerest congratulations.

It is a pleasure to give due credit, and to Dr. W. C.

[1] On the Simplest and most Effective Treatment of Diphtheria: A paper read before the Congress of the American Laryngological Association at Philadelphia, 1886. Vide Transactions of that Association for 1886.

Reiter, deceased, of Pittsburg, belongs the honor of teaching and practising this method during his long and honorable career in this city. But as the doctor was generally accused (but not justly so) of giving calomel for every ill, his teaching did not receive the attention it merited with regard to the treatment of pseudo membranous croup by calomel, and as the treatment had never been a general one before Dr. Reiter's time, I was impelled to make it known to the profession. In the year previous to that in which I published my essay, I found in a non-medical book [1] an account of the exhibition of calomel in croup, about 1797 to 1799, and as I had nowhere in medical works been able to find a perpetuation of the plan, I thought it fair that I should give an account of it, with due credit to Dr. Hamilton, of Edinburgh, Scotland, who was, so far as I could learn, nowhere recorded in medical annals, though he richly deserved to be.

As over seven years have passed since the publication of my article, it may not be uninteresting, to repeat my quotation from the book:

"A few months after the birth of Sydney Smith's daughter, he went in the summer for a short time to Burntisland, a small sea-bathing place at no great distance from Edinburgh, for the recovery of his wife's health; and here but for his courage and firmness, he would have lost his long-wished-for daughter in a way he had not at all anticipated. When only six months old she fell sick of croup with such fearful violence that it defied all the remedies employed by the best medical men there. The danger increased with every hour. Dr. Hamilton, then one of the most eminent medical men in Edinburgh, was sent for, could not come, but said, 'Persevere in giving two grains of calomel every hour; I never knew it to fail.' It was given for eleven hours; the child grew worse and worse; the medical man in attendance then said: 'I dare give no more; I can do no more; the child must die; but at this age I would not venture to give more to my own child.' 'You,' said Sydney Smith, 'can do no more; Dr. Hamilton says to us, "Persevere;" I will take the responsibility, I will give it to her myself.'" He gave it and the child was saved.

To anyone caring to see the brochure of Dr. Reiter, which is little known of, and is so peculiar in its style as to entitle it to be considered an oddity in medical literature, I will say that it was published by J. B. Lippincott & Co., in 1878, and it is entitled "A Monograph on the Treatment of Diphtheria based upon a New Etiology and Pathology," by William C. Reiter, A.M., M.D.

The matter of detailing cases from my case-books, which will supply several hundred cases treated by calomel, with the usual symptoms and repetition of treatment, I do not deem altogether necessary here, but I shall repeat here some rules which I gave in my essay for the use of the practitioner:

1. Give calomel untriturated and unmixed with sugar, in doses of two to five grains, to a child from two to five years old, every two hours, either dry on the tongue or floated on a teaspoonful of water, until you procure the peculiar chopped spinach-colored stools, *i.e.*, stools looking much like the water polyps one sees floating in an old-country roadside watering-trough.

2. When these stools are procured, then increase the interval but don't diminish the dose. Continue to secure two stools daily, at least.

3. Give little, if any other medicine.

4. Give light nutritious diet.

The treatment is so simple and easily followed, both by practitioner, nurse, and patient, and the results are so far superior to any other I have tried, that I again recommend a trial of it to the profession with confidence.

W. H. Daly, M.D.

Pittsburg, Pa.

New Instruments.

SOME REMARKS ON THE ADMINISTRATION OF ANÆSTHETICS.

With a Description of a New Anæsthetizer.

By A. M. ADSIT, M.D.,

Hastings, Minn.

For years I have been convinced that the methods in vogue for the administration of anæsthetics are not only faulty but in many cases extremely dangerous. Physicians seem to forget that neither chloroform, ether, nor any other anæsthetic can be substituted for air.

The most frequent method of administering ether is by saturating a towel, covered with a cone of paper. This device is held tightly down over the face, almost wholly excluding the air. The patient is compelled to breathe the vapor but slightly diluted. Administered in this way it acts as an irritant to the mucous membrane, and the initial effect is the arrest of inspiration.

A study of those cases in which death is reported to have been caused by the administration of ether, demonstrates that a majority die during the initial stage of anæsthesia, or at least exhibit marked signs of disturbed respiration resembling asphyxia.

The symptoms usually given as arising from the administration of ether, during the first stage, are the following: The face becomes flushed, red, or slightly livid. The veins become distended, and the arterial pulsation in the temples more pronounced. The pulse becomes full and quick. The respiration is increased in frequency, is sometimes catching and shallow, and sometimes scarcely perceptible, ceasing for considerable intervals. Coughing is excited by the local stimulating effect, and there is an increase in the quantity of mucus. These symptoms teach two things: first, that ether strikes its first blow at the respiratory centres; second, that the vapor has not been given sufficiently diluted with air. It is generally admitted that death from ether, as a rule, is due to direct paralysis of the respiratory centres. I do not doubt that the respiratory centres are affected by the ether; but I believe that the paralysis has a greater cause in the limited supply of air and in the hasty initial administration. I believe that the greatest danger in the inhalation of ether lies in this initial disturbance of inspiration, preventing the proper æration of the blood, and, as a result, we have the flushed face, the distended veins, the coughing, the jerky, catching inspiration, the increased flow of mucus, and the wild struggle for liberty. To avoid these bad effects two rules must be observed; first, begin the administration with air lightly charged with ether; second, always permit all the air necessary to sustain life comfortably. By this I mean as much as the patient would require were he engaged in his usual pursuits

There is no good reason why a patient does not require as much air while taking an anæsthetic as at any other time. If you think that they secure the needed supply of air, place a cone over your own face and permit some one to hold it down tightly for five minutes. I think you will experience difficulty in inspiration, have a sensation of suffocation, and the people about you will observe that your face is flushed, the veins distended, and that your complexion is a shade darker than usual.

I think that it is generally taught that in order to produce anæsthesia with ether you must exclude the air, or at least only admit sufficient to produce evaporation. This doctrine is founded upon a false principle. All substances, chemicals, or mixtures that will not produce anæsthesia when diluted with air are not anæsthetics proper, but rather asphyxiating agents.

Chloroform and ether are the most perfect anæsthetics we possess, both being capable of producing anæsthesia quickly when inhaled with an abundance of air. After anæsthesia is obtained, then the all-important point is

simply to maintain the anæsthetic condition. This can be accomplished by adding only a sufficient quantity of the stupefying vapor to accurately balance or replace the amount being constantly eliminated. Elimination takes place quite slowly; hence but a small quantity should be given each minute and at regular intervals. At this stage the greatest danger lies in the over-saturation of the tissues. How often at this period we see the physician add one, or even two, drachms of ether, or twenty to sixty drops of chloroform to an inhaling or evaporating apparatus, and as often observe the inspirations nearly cease, requiring the instant removal of the anæsthetic for the purpose of giving the patient a few inspirations of pure air. It is this careless method of administration which causes the tissues to become over-saturated and paralyzes the nerve centres, when, in reality, at this stage all danger should have been past.

In the administration of ether not more than fifteen drops should be used the first minute, or the equivalent of one drop to each inspiration. Of chloroform, not more than four drops should be given the first minute, and the quantity given at any one time ought not to exceed fifteen drops. We need not fear prolonging the stage of excitement. This stage is more frequently caused from the sensation and belief, on the part of the patient, that suffocation is imminent, than from the direct effect of the anæsthetic.

After the first fifteen drops of ether have been inhaled the patient will have become accustomed to the vapor, and all fear of impending danger removed from his mind. Now, we can gradually increase the quantity to from thirty to sixty drops per minute, or, if we are using chloroform, from five to fifteen drops. As soon as anæsthesia is obtained, the quantity should be reduced to about fifteen drops of ether, or four of chloroform, which will quite accurately represent the elimination.

In order to properly observe the above instructions a specially constructed apparatus is imperative. The essentials of such an inhaler are:

1st. An opening admitting sufficient air to enable the patient to breathe comfortably, and the air should pass down through the vapor so as to be thoroughly mixed with it.

2d. A reservoir large enough to hold a sufficient quantity of the anæsthetic to maintain anæsthesia from one to three hours.

3d. An apparatus regulating or controlling the flow of the anæsthetic.

4th. It should be constructed so as to prevent evaporation into the room, for in the inhalation of ether the vapor is not only a source of annoyance to the surgeon and his associates, but, in some cases, even dangerous from its inflammability.

5th. It should have a large evaporating surface, so as to evaporate the anæsthetic quickly and thoroughly as it falls from the reservoir, for it is only in this way that the quantity used can approximately represent the amount inhaled by the patient each minute.

6th. To obviate the necessity of the patient exhaling through the instrument, and thereby forcing the vapor into the room, the inhaler should have an opening admitting the vaporized air, and another to carry off the expired air. These openings should be closed by valves, and the slightest breath should be sufficient to move them.

Fig. 1 represents a section of my instrument, with shield attached. The different parts of the instrument are represented by letters, and are thus explained:

A represents a screw valve passing down through the reservoir *C* into the funnel *D*. By this device the flow of the anæsthetic is controlled. *B* indicates the opening through which the reservoir is filled. *E* represents a space for carrying the shield *K* when not in use. *F* represents openings through which a full supply of air, charged with the anæsthetic, passes down for inhalation by the patient. *G* and *I* represent valves. These valves are held in place by steel springs. The springs are so constructed and arranged as to evenly balance or neutralize the weight of the valves. By this device the valves are moved by the slightest breath, for the resistance of gravity and friction are entirely overcome. *H* and *J* represent openings through which the patient exhales.

Fig. 2 represents one of the perforated plates and thin blotting-pads, by which we secure a large evaporating surface.

The instrument which I have been using is roughly constructed, and imperfect in several respects, yet I have

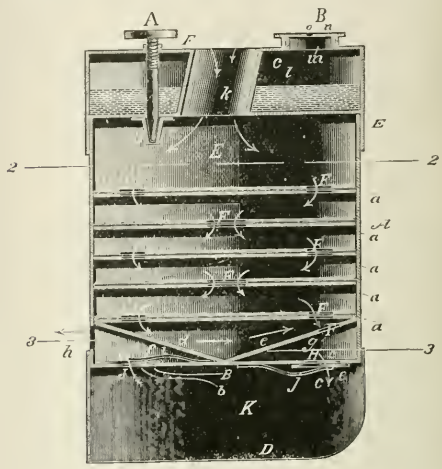

Fig. 1.

been able to produce anæsthesia with ether in from two to twenty minutes. The quantity of ether used varied in different cases. I have generally found one-half ounce to two ounces sufficient for minor surgical operations.

The stage of excitement I find to be scarcely perceptible, and my patients do not complain of difficult breathing. Their complexion may be flushed, but there is no coughing or jerky catching respiration. The quantity of mucus is not materially increased.

Charles Truax Green & Co., of Chicago, Ill., have made me an instrument constructed on the principles set forth in this article. Its dimensions are as follows: Height, a little over five inches; greatest diameter, three and one-half inches; capacity of reservoir, three ounces.

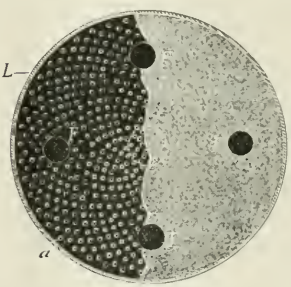

Fig. 2.

I believe this inhaler to be safe, economical, and as well adapted to the administration of chloroform or mixtures as ether. Suspended by an elastic cord from the ceiling, it makes a very convenient instrument for the administration of chloroform in obstetrical practice.

The patient grasps the inhaler and holds it down over her face, but as soon as the muscles of the arm and fingers relax, the elastic cord carries it away, and the valves close, preventing the escape of the anæsthetic into the room.

Medico-philosophic Definitions. — *Health.*—A unit that gives value to the zeros of life (Jousset). *Hunger.*—Dyspepsia of the poor. *Remorse.*—Moral indigestion. *Life.*—That which holds matter together (Bichat).

A NEW INTRA-UTERINE IRRIGATOR.

By ALAN B. MURRAY, M.D.,

COKEDALE, MONT.

THE ordinary metallic intra-uterine irrigator, having direct and return tubes, is objectionable for several reasons, the principal one of which is that it is almost impossible to properly clean the tubes. After having tried a variety of the instruments commonly in use, it occurred to me that an irrigator made of hard rubber, with the inner or direct tube removable, would do away with several of the objectionable features. Acting on this idea I have had Messrs. Tiemann & Co. make for me the instrument here illustrated. Made of hard rubber, it is unaffected by any

of the usual irrigating solutions. After use, the removal of the inner or direct tube renders the cleansing of the return tube a simple matter. After properly cleansing and boiling, the instrument is rendered absolutely aseptic. There are no points within the tube for the lodgement of shreds of tissue or blood-clots.

RING'S OCULAR MASK.

By FRANK W. RING, M.D.,

NEW YORK.

THIS mask is designed for the purpose of protecting eyes from injury, especially after cataract extraction. Eyes are not infrequently lost after extraction of cataract, from force inflicted by the patients, either consciously or unconsciously, and this device serves as a complete protection, as it is quite impossible to disturb the eye without breaking the tapes.

One great advantage consists in the security with which the bandage may be permanently removed at the end of from thirty-six to forty-eight hours, by simply filling in the oval depression in the mask with cotton—it being desirable to relieve the eye from the pressure of the bandage, and consequent heat and soaking thereby produced, as soon as possible.

The patients are always very anxious to have the mask applied, especially at night, as it gives them a feeling of security against accident.

This shield is made of papier-maché, lined on the outside with silk and inside with linen.

It is made to fit the contour of the average face. If the nose should be rather prominent, cut two snips either side of the nose-piece. If less prominent, fill in the space with a little cotton. Surgeons using other dressing than the roller bandage will find it of especial advantage. It is designed to be used immediately after operation, and may be continued for some days. If one desires to give the patient light, a perforation may be easily made with a penknife in front of the unoperated eye.

As a matter of cleanliness and safety against contagion a new mask should be used for each patient, especially as the cost is so moderate.

These masks may be obtained from E. B. Meyrowitz, 104 East Twenty-third Street, New York.

BLUNT-HOOK AND HOOK-KNIFE FOR FACILITATING THE OPERATION FOR SECONDARY CATARACT.[1]

By JOHN HERBERT CLAIBORNE, M.D.,

ADJUNCT-PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC.

THE instruments which the accompanying cut represents are intended to facilitate the operation for secondary cataract. It is a well-known fact that after the lens has been extracted from an eye the remains of the capsule are often found to be so dense and opaque that the usual good results of the operation are not attained. This necessitates the operation for the so-called secondary cataract.

Owing to the fact that the attachments of the capsule to the ciliary muscle are insecure and easily ruptured, and owing to the extreme instability of the capsule as it lies between the aqueous and vitreous humors, it becomes a difficult undertaking to tear a hole in the capsule either with a single needle or with two. The endeavor to attain this end with one needle or knife has largely been supplanted by the operation with two needles, in which it is at tempted to *tease* the capsule apart. That even this is difficult to accomplish will be recognized by all who have tried it. The two instruments, as can be seen in the cut, are a blunt-hook and a sharp-pointed knife-hook.

The idea of having them constructed came to me in the following wise:

I removed a hypermature cataract from a woman and had the misfortune to find an extremely dense capsule remaining. It was, indeed, so dense that very little improvement in vision was attained through the operation. Two attempts were made with the teasing needles to tear a proper aperture in the capsule. Failure attended each attempt. The capsule was slightly torn, but not sufficiently. A dense tongue of capsule hung in the rift, and could not be displaced by the teasing needles. Two weeks later I determined to use a small keratome and tear away the tongue with forceps.

A small opening was made at the upper sclero-corneal margin with a keratome, but when I endeavored to grasp the piece of capsule it escaped from the jaws of the forceps and retired to the vitreous chamber. Repeated attempts failed. I was on the point of giving up the task when I thought of Stephens's small tenotomy-hook.

I introduced this instrument through the wound and neatly tucked the tongue of capsule back behind the iris, leaving a perfectly clean and proper pupil. It has remained ever since.

Stephens's hook is a trifle large and hardly has the proper curve for this work.

It will be seen that the blunt-hook here shown is beaked. The knife-hook has the same curve, is very sharp-pointed, with a cutting edge that extends to the

[1] The writer is not unaware that a hook has been devised by Stellwag for the purpose of removing the entire capsule, when it undergoes chalky degeneration, through a linear incision. The method of procedure suggested here differs from that of Stellwag in several respects. Hence he feels himself warranted in presenting the above.

straight shank. The blunt-hook is intended for such cases as the one I have described; the cutting-hook for those in which the capsule has not been torn or split. A small opening should be made at the sclero-corneal margin with a keratome or cataract-knife, and the hook inserted with the curve first. After entering the anterior chamber the point may be turned downward, pushed through the capsule, and the capsule lacerated in any direction or in several.

The operation of secondary cataract has to be frequently repeated. This is a disadvantage, for on each occasion two punctures have to be made in the cornea, the chances of infection are multiplied, and a small opacity often remains at the point of entrance of the needle.

This is certainly not a desideratum. The opening at the site of the old wound when a keratome or cataract-knife is employed heals rapidly under antiseptic surgery, and the curve of the cornea is not appreciably altered by the resulting cicatrix.

It is hoped that these two instruments may be of use in rendering the operation of secondary cataract more satisfactory.

Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Early Sanitation.—As far back as the reign of Richard II. we find an act for "the punishment of them which cause corruption near a city or great town to corrupt the air" (12 Rich. II., c. 13, A.D. 1388), the preamble of which notes that so much filth "be cast and put in ditches and other waters, and also within many other places . . . that the air there is greatly corrupt and infect, and many maladies and other diseases do daily happen." This is essentially sanitary legislation. A century later we find an act under the heading, "Butchers shall kill no beasts within any walled town, or Cambridge" (4 Henry VII., c. 3, A.D. 1487). The preamble of this speaks of the "corruptions engendered . . . by reason of the slaughter of beasts and scalding of swine," the "unclean, and corrupt, and putrified waters," and goes on to the remarkable statement that "in few noble cities and towns, or none within Christendom . . . the common slaughter-house of beasts should be kept . . . within the walls of the same, lest it might engender sickness, unto the destruction of the people." Under Charles II. the "Act for rebuilding the City of London" (19 Ch. II., c. 3, A.D. 1667) provides for the "cleansing and scouring of vaults, sinks, and common sewers," and a few years later, again, we find "an act for the better paving and cleansing the streets and sewers in and about the City of London" (22 and 23 Ch. II., c. 17, A.D. 1670). We must be just to our ancestors; though they undoubtedly had not much science (and did not use long words ending in "ation"), the idea of health as a matter of public concernment was not foreign to their minds. The difference is that what were sanitary instincts in them have developed into sanitary methods with us.—*The Spectator.*

Women Doctors Forty Years Ago.—Medicine as a profession for women is less than fifty years old. Dr. Marie Zakrzewska, of Boston, has recently published an interesting account of the early struggles of the pioneers in this particular field. Harriet Hunt and Elizabeth Blackwell were stirred by the idea that an important work might be done by well-instructed medical women. The materialization of this view resulted in complete social ostracism, impossible to be endured by any but the strongest and most courageous women. No woman doctor ever earned a living before 1860. No respectable family, in any common respectable neighborhood, would let rooms to a woman physician. Even when friends gave her shelter, a business card or sign was not allowed. The lack of practical training was really the stumbling-block, and the cause of all this prejudice.

BOOKS RECEIVED.

THE THEORY AND PRACTICE OF MEDICINE, PREPARED FOR STUDENTS AND PRACTITIONERS. By James T. Whittaker, M.D., LL.D. Octavo, 840 pages; more than three hundred engravings and one chromo-lithographic plate. Extra muslin, price, $5.75; leather, price, $6.50. William Wood & Co., New York.

ANATOMY, DESCRIPTIVE AND SURGICAL. By Henry Gray, F.R.S. Edited by T. Pickering Pick. New American from the thirteenth English edition. 8vo, 1129 pages, illustrated. Lea Brothers & Co., Philadelphia, Pa.

A DICTIONARY OF MEDICAL SCIENCE. By Robley Dunglison, M.D., LL.D. Edited by Richard J. Dunglison, A.M., M.D. New (21st) edition, thoroughly revised, greatly enlarged and improved, with the pronunciation, accentuation, and derivation of the terms. In one imperial octavo volume of 1181 pages. Cloth, $7.00; leather, $8.00. Lea Brothers & Co., Philadelphia, 1893.

A TEXT-BOOK OF OPHTHALMOLOGY. By William F. Norris, M.D., and Charles A. Oliver, M.D. In one octavo volume of 641 pages, with 357 engravings and 5 colored plates. Cloth, $5.00; leather, $6.00. Lea Brothers & Co., Philadelphia, Pa., 1893.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY. Vol. XIV. Sutures–Universally. Royal 8vo, 1016 pages.

ESSENTIALS OF MINOR SURGERY. By E. Martin, M.D. Second edition. 12mo, 166 pages, illustrated. W. B. Saunders, Philadelphia, Pa. Price, $1.00.

HEATH'S PRACTICAL ANATOMY. Eighth edition. Edited by W. Anderson. 8vo, 744 pages, illustrated. P. Blakiston, Son & Co., Philadelphia, Pa. Price, $5.00.

ESSENTIALS OF BACTERIOLOGY. By M. V. Ball, M.D. Second edition. 12mo, 205 pages, illustrated. W. B. Saunders, Philadelphia, Pa. Price, $1.00.

THE CLINICAL USE OF PRISMS AND THE DECENTERING OF LENSES. By E. Maddox, M.D. Second edition. 12mo, 170 pages, illustrated. John Wright & Co., Bristol, England. Price, 4s. 6d.

MINOR SURGERY AND BANDAGING. By H. R. Wharton, M.D. Second edition. 12mo, 529 pages, illustrated. Lea Brothers & Co., Philadelphia, Pa.

SYPHILIS. By Edward Cotterell. 12mo, 36 pages. John Bale & Sons, London, England.

TRANSACTIONS OF THE ASSOCIATION OF AMERICAN PHYSICIANS. Eighth Session, May 3–June 1, 1893. Vol. VIII. 8vo, 402 pages.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF GEORGIA. Forty-fourth Annual Session. 1893. 8vo, 426 pages, illustrated.

LECTURES AND ESSAYS ON FEVERS AND DIPHTHERIA, 1849 to 1879. By Sir William Jenner. 8vo, 581 pages. Macmillan & Co., New York. Price, $4.00.

THERAPEUTIC REFLECTIONS.

By SIMON BARUCH, M.D.,

NEW YORK.

THE prudent merchant resorts from time to time to an inventory of his obligations and assets, in order that he may diminish the former and increase or enhance the value of the latter. It would surely inure to the satisfaction of the physician and to the advantage of his suffering clients, if he would follow this example. This I propose to do, asking your indulgence if I bring before you trite observations and experiences which are not novel to you. Indeed if my remarks call forth a responsive echo in your minds, this will demonstrate that I have truly given voice, as is my intent, to actual observations at the bedside. From such I propose to draw lessons and to elicit discussions, which may enable some of us to leave this hall better armed for the battle with disease and death which we are daily waging.

Enthusiasm in therapeutics is indeed unwarranted, for the history of medicine abounds in the rise and fall of the most brilliant structures, in the explosion of the most plausible theories, and, what is more painful than all else, the overthrow of remedies which have seemed to be so firmly intrenched in the minds of the foremost physicians for so long a period that they seemed impregnable against all attacks. I need but call from the shadows of the past the spectre of venesection. Though hoary with age, and lauded by men whose works are to day revered, this therapeutic flower withered under the light of modern physiology and pathology.

Another remedy, once the sheet-anchor in many serious diseases, has been dethroned and has taken the subordinate though most useful position of a simple anodyne.

Time was when in certain forms of peritonitis opium was the chief remedy, because it "acted as a splint to the inflamed surfaces;" to-day, Lawson Tait's teaching, that it is dangerous and that the opposite treatment by saline purgatives is more useful, is most successfully followed. Let him who grows fulsome in his laudations of a remedy, bear in mind how these mighty giants have fallen and endeavor to rescue the remedy he espouses from a similar fate by judicious tests and unprejudiced comparisons. What is the status of therapeutics to-day? What are the assets with which the physician may meet his daily obligations to cure the sick?

Let us confess that the materia medica consists chiefly of medicinal agents, whose action on the human body, with the exception of very few, is uncertain, and whose effect upon disease is either neutral or unreliable. How often can we conscientiously say that we have accomplished, by means of any medicinal agent or combination of such agents, the cure or removal of any disease? With the exception of quinine, and perhaps of mercury and the iodides, there is not a single medicinal agent which may be regarded as actually curative. And yet we constantly meet intelligent physicians who insist upon the contrary, and in so doing neglect remedies that are more valuable because their action is clearly explicable upon rational principles. Faith in drugs is almost as frequent among physicians as faith in being drugged among patients. As an illustration I would refer to a case of acute entero-colitis in a child which I saw recently in consultation with a gentleman who is justly esteemed by colleagues and patients. The usual symptoms, fever, a large number of evacuations, loss of sleep and appetite, etc., were present. Upon the antiseptic theory salol had been frequently administered; to meet other symptoms bismuth, Dover's powders, and other remedies. The simple substitution of intestinal irrigation for the salol, together with an abolition of the milk diet, produced a complete change in this case. It may be held that the latter course is that recognized as proper at the present time. But I cite this case to show that it is not so universally recognized as it should be, and to illustrate the difference between medicinal and nonmedicinal remedies for the purpose of emphasizing the chief point of this paper, viz., the too frequent neglect of those nonmedicinal agents, whose action in disease is so simple, rational and clinically effective, and the unhappy reliance on pharmaceutical preparations whose effect, like that of salol, as an intestinal antiseptic, has never been definitely proven. The vast majority of remedies in our pharmacopœia have no better foundation than salol, and yet they are constantly used upon the strength of so-called clinical observation.

The rock upon which therapeutics has always split, and which continues to menace us because we seem not to profit by the teachings of history, is the treatment of symptoms. In my student days, when venesection was in its last gasp, veratrum viride had in the South gained many adherents. A rapid pulse was the chief manifestation of all fevers; here was a remedy which in small doses perfectly controlled the pulse. A reduction to one-half of its rate could readily be produced. I shall never forget one of the first cases of pneumonia which I treated as house physician of a hospital.

Veratrum was given until the pulse was reduced from 140 to 80, and yet the consolidation continued to the bitter end, and the patient succumbed with a normal pulse. History repeats itself in the application of the coal-tar antipyretics recently so much in vogue.

The temperature may be readily reduced from 105 to 100 and, as in the case of veratrum, we may even have the questionable satisfaction of seeing the patient die with a normal temperature. This striving after symptomatic remedies is the unhappy legacy which our forefathers have bequeathed to us. It is an echo of this mysticism which veiled their idea of disease and which led them to regard the latter as an essence rather than as a manifestation of certain disturbances in the economy which rendered the latter incapable of regulating its functions. Therapeutics would be a simple art in this day of patent medicinal agents, could its aims be merely filled by meeting certain symptoms or certain definite alterations in the functions of the body.

As pathologists it is our function to discover changes in the organs, but as physicians who stand at the bedside of those who implore us to heal them, we can accomplish but little if we are called to act after these changes in the tissues have taken place. As has been well said by another, the physician who is called to combat a case of well-established organic disease with remedies may be likened to the sanitarian who is called upon to prevent an infectious disease by disinfecting the emanation of the patient. The physician who would cure, must assume the task early; in the beginning of that anomalous relation between capacity of the system for work and the demand upon it for work which is really the inception of all tissue changes and which may be prevented by limiting the labor imposed upon the organs. To discover this anomalous relation in its incipiency, and to guard against

its development into organic disease, is the function of the true physician. The latter must soon discover that in this contest medicinal agents play an unimportant rôle when compared with those methods which we learn by observation of nature's course in health. As an illustration may be mentioned dilatation of the stomach, an organic alteration which is most commonly the result of long-continued insufficiency of its functions. The early recognition of the causes, the adaptation of diet, mode of life, manner of eating, gastric lavage, etc., to each individual case, will conduce far more to the prevention and cure of the organic disturbance than all the medicinal agents, from ancient gentian to modern strychnine, from muriatic acid to pepsin. No physician of experience can gainsay this proposition. It must be patent to the most enthusiastic poly-pharmacist that he accomplishes only an amelioration or removal of certain manifestations of disease—a result which may and probably does facilitate a restoration to health, but is rarely if ever the direct means of such restoration.

In the large preponderance of acute diseases, among which may be numbered all infectious diseases, the administration of these medicinal agents is not only entirely symptomatic, but in many instances absolutely harmful. Take as an example a case of appendicitis. The tendency to treat such a case as localized peritonitis and to meet the symptoms tempts the average practitioner to prescribe morphia to subdue pain, ice or poultices to the right iliac regions, food to satisfy the bugaboo of coming failure of the vital powers, and an antipyretic to reduce the temperature. This is not a fancy picture but a chapter from personal experience. Coming into contact with such a case as a consultant, how can the latter take his bearings? Like a mariner in a fog he is handicapped, pain is absent, temperature perhaps normal, all is serene, except the anxious countenance, perhaps vomiting, and the attendant's fear that something may be brewing.

Here the remedies employed have hidden the enemy's movements, the physician has become the ally of the disease; diagnosis and prognosis become difficult, and valuable time may be lost. I am sure many of my hearers have passed through this experience. Am I presuming too much then, if I counsel that in the early stage of disease, the warning of Italy's lamented clinician, Cantani, be constantly before our eyes, "Nil Nocero." To make a clear diagnosis is important for a favorable issue. It is better for the patient to suffer some discomfort than to have his life jeopardized by remedies which obscure the real issues of the case. Later in the case, too, it should be our constant endeavor to avoid damaging the system which is staggering under disease and cries out for every possible aid on the part of the physician. In this day of powerful symptomatic remedies, veratrum for the pulse, antipyretics for the temperature, pilocarpin for the secretions, morphia for the pain, chloral for sleeplessness, all agents which strike mighty blows at the manifestations of disease, often lead to disaster by lulling the physician into a false sense of security. And yet how eagerly they are resorted to, daily observation teaches but too sadly. It may be urged in defence of such a course that the patient and his friends are importunate to have the pain, the fever, etc., combated. Medicine is a business, said a gentleman in a recent discussion on antipyretics, and we must yield to the demands of our patient to be relieved of his fever. It has doubtless been your experience, as it has been mine, that much can be accomplished by placeba, by mild remedies, by gentle reassurance, and by taking the friends into our confidence.

When there is severe pain, as in some cases of appendicitis, I prefer to keep the patient gently under the influence of chloroform until a decision for or against operative measures can be reached. In a case of perforating appendicitis at Long Branch, two years ago, morphia administered by an able colleague was discontinued, chloroform substituted for twelve hours with intervals, until Dr. Wyeth arrived. The patient was not aware of his arrival, nor of the laparotomy performed on her until an hour afterwards. She made a good recovery. Ten years ago the belief had become all but unanimous that the only direction in which therapeutic effort was most conducive to the patient's benefit, lay in following the tendency of nature in each disease. *Vis medicatrix naturæ* is an old rallying cry of the profession, but one which did not gather many steadfast defenders. At one time a complete therapeutic Nihilism, emanating from the Vienna school, threatened to become its expression. But when the chemist evolved those potent therapeutic sledge-hammers which could beat down symptoms, the gentle hand maiden Nature was thrust aside, and the patient was beaten down with the symptoms. To-day a reaction is happily setting in. Once more are heard warning voices that bid us follow Nature's prompting. To join these and to re echo them in these halls, is the purport of my paper to-night. For instance, rest is the first prompting of nature in diseased conditions. What can be more simple and obvious than rest in inflammatory conditions? The surgeon puts an inflamed joint into a splint and trusts to nature, *i.e.*, the restorative powers of the system to heal the disease. May not an acutely inflamed kidney be treated in a similar way? Its functions must go on. in this respect it differs from the inflamed joint. But the intelligent physician, knowing that the chief function of the kidney is to eliminate urea, so arranges the patient's diet that this work is reduced to a minimum; knowing that other functions of the kidney may be vicariously taken up by the skin and bowels, he endeavors to utilize these vicarious eliminants for the purpose of relieving the inflamed organ from labor. And yet we find the contrary so often that I may be pardoned for emphasizing here the necessity, nay the duty, of doing in internal diseases what is so obvious and so successfully done in external diseases. Only recently I saw a case of acute nephritis with a well informed physician of ten years' graduation from a most exacting school, a hospital physician too, who treated the case with digitalis and acetate of potassium as diuretics, because the secretion was reduced to nineteen and a half ounces, paying no attention to the physiological aids which nature points out.

In acute conditions rest must be provided; in chronic conditions rest, judiciously alternated with gentle exercise of the functions of the diseased organs, is indicated, and will prove far more useful than medication. Let me not be understood, however, as despising the latter. There are few to whom I should be willing to yield independence upon our well-tried medicinal agents. But I spurn them if their action is based on empirical observation alone, the *ipse dixit* of one or more men.

Those medicines alone which evince their presence in the system by certain definite signs, have my confidence. When quinine is administered in sufficient doses to cinchonize the patient, I know, without fear of contradiction, that whatsoever effect is produced on the paroxysm may be attributed to it; when it is used in small doses three times a day, for so called malaria, I spurn the remedy as I do the disease. True malaria will as surely yield to cinchonization before the paroxysm, as spurious malaria (the so-called civic or international malaria) will fail to yield to it. This much I may say positively, from a long experience on the banks of Southern rivers.

To refer to the value of salicylic acid in acute articular rheumatism would seem supererogation in this assemblage. But bear with me if I apply it as an illustration of my views on positive medications, for which I plead. I have seen capable men in hospital and private practice order five grains of salicylate of soda every two hours in rheumatism. Is it surprising that these gentlemen are unwilling to testify to the value of this remedy? Twenty grains every two hours of pure salicylic acid until tinnitus aurium is produced and affords evidence of its having been absorbed, is the method I adopt. I can therefore not be charged with antagonism to reliable medicinal agents. I would only inveigh against the thousand and one impotent drugs with which the sick are deluged—drugs

To be continued

without ascertainable effects upon the economy, though many frogs and dogs may have died and lived under their experimental use, have no charms for me. If careful observation among various classes of patients in country and city, private and hospital practice, in peace and war, may crystallize one's experience into some definite shape, permit me to say here to-night that far more actual curative results may be obtained from watching and cautiously following the tendencies of a disease and applying those agents which are potent in maintaining the system in health, viz., rest, exercise, diet, baths, change of environment—than from the most intelligent application of medicinal agents, highly though I esteem some of these. To demonstrate this proposition in a representative acute disease, let us choose typhoid fever. Here we have a malady which runs a more or less definite course, whose etiological factors are beyond our control. We are called upon here to contend against a foe of great power. The system is overwhelmed by the toxines due to the biochemic activity resulting from the life or death of the micro-organism to which the disease is traceable. Be that as it may, we do know clinically that we stand in the presence of an intense toxæmia which exercises a depressing, a devitalizing influence upon the nervous system. Every function which draws its force from the latter suffers visibly. The brain itself is more or less overwhelmed.

The patient lies in a semi-stupor, his face is expressionless, the eyes dull and glassy, lids have closed (typhoid countenance). His perceptions are blunted, he mutters incoherently, he has no control over his sphincters. In brief, there exists great cerebral depression.

The pulse is rapid, feeble, dicrotic—all manifestations of cardiac enfeeblement. The blood is deteriorated; its leucrocytex decreased. The respiration is shallow and ineffective; hypostatic conditions, bronchial congestions, and pneumonia result. The temperature is elevated, either because of the loss of regulatory influence of the heat centres, or by diminution of heat radiation from the skin, or both. The secretions are impaired; the urine, for example, is concentrated, highly acid, and loaded with products of active tissue-change. These, together with the shallow respiration, are evidences of the crippled condition of the emunctories, whose integrity is vitally important for the maintenance of health. In brief, the patient's vitality is sapped because the organs upon which it depends receive imperfect sustenance from the nervous system. Modern physicians are agreed that every effort should be made to maintain the patient's vitality, to counteract the palpable toxamenia, be it due to micro-organism or not, in short to sustain life until the disease has run its course. The expectant treatment, so called, was the outcome of the fatality of the former spoliative treatment. Liebermeister's great success in the Bâsle Hospital made high temperature the chief point of attack. So long as we had no real medicinal antipyretic it was not clear whether to the (medicinal) quinine or to the (physiological) baths administered by him was due the superior results which he attained. The high temperature idea was plausible, and gained many adherents rapidly, until the discovery of the coal tar series brought to the physician the first real antithemic remedies. A few years' use of these positive remedies has awakened the profession to the fallacy of regarding high temperature as the chief lethal agent. To-day a reaction is impending. While in the medical centres the coal tar antipyretics are being reluctantly abandoned, it will be long ere the less enlightened rural practitioner will let this comforting drug slip from his fond grasp. The same fate has befallen other medicinal agents, which, however, were not so readily abandoned, because their specific effects are not so patent; for example, veratrum, to which reference has been already made. To day internal antisepsis has become a fad. Though claiming to be based upon the attractive germ theory, which threatens to upset all past pathology, the advocates of this method have thus far failed to demonstrate its tenability, by actual experiment. Until such demonstration shall be made, it is difficult to accept the idea that the mild antiseptics (naphtholin naphthol, sulpho-carbonate of zinc, etc.), which are applied in typhoid fever, are capable of disinfecting a long intestinal canal, containing more or less fluid, which dilutes or otherwise neutralizes them. Moreover, long before the disease has been diagnosed, during its incubation, these pathogenic germs have been circulating in the blood. Having already passed into the lymphatic glands and spleen, it borders on the absurd to assume that these antiseptics are capable of searching out and destroying them. When the patient comes under observation he is really suffering more (if deductions from recent investigations may be accepted) from the toxines generated by these pathogenic bacilli than from the presence of the latter. Disinfecting the intestinal canal may prevent some auto-intoxication, but it surely cannot reach the pathogenic germs nor its toxines.

That there are fewer bacteria in the fæces after some of these antiseptics are administered, even if it had ever been positively demonstrated, does not by any means justify the deduction that the intestinal mucous membrane has been rendered aseptic, much less so than that pathogenic germs have been destroyed. The surgeon would not be content with such a demonstration. Why should the physician be? Hence this pseudi-scientific claimant to our faith in numerous drugs is feeble indeed, and must go the way of its predecessors.

It follows, from these brief considerations, into which the lack of time does not permit me to enter more fully, that the only active medicinal agents, those agents whose effect has been positively demonstrated, have simply afforded the physician means for suppressing certain pronounced symptoms. Pulse and temperature are still important indices to the condition of the patient. Nevertheless, despite the fact that we have positive medicinal agents to bring them to an almost normal standard, they are proven absolutely harmful by good observers. The physician, therefore, is forced to acknowledge his entire dependence on the *vix medicatrix*, which he attempts to aid by withholding all injurious elements and utilizing physiological remedies.

Rest, seclusion, proper adaptation of food and drink, and cleanliness are the chief agents in the so-called expectant plan of treatment, whose superiority over the former spoliative and the present antipyretic treatment clinical observation has demonstrated. There is, however, one physiological remedy which, judiciously adapted to the case as are diet, rest, etc., has produced a vast improvement in the condition of the patient and in the final issue of the case. The bath treatment of typhoid fever no longer requires defence before an enlightened medical audience. It has demonstrated its value in so many clinical texts on large numbers, that I need refer here only to its salient advantages. Being a physiological agent, *i.e.*, an agent if used in health, promotes the latter, its judicious application is as potent as that of air, food, and rest. Its injudicious application is as injurious as that of the latter agents. For example the wrapping of a typhoid patient in a cold, wet sheet, and sprinkling it with ice water until the temperature is reduced—a method actually used by eminent practitioners—is as injurious to the patient as the exposure to draughts of cold air, or the administration of a mixed diet would be. In the one case it would still be bathing, in the other it would still be ventilating and feeding. In all it would be an injudicious, senseless application of useful, remedial agents.

The judicious application of ventilation and diet are pretty well understood by the profession, the judicious application of water is unfortunately still a *terra incognita* to the large majority. It is true nearly all utilize water in some form. Cold sponging is quite commonly adopted in fever, and yet the feeble refreshment obtained from it may be compared to the ventilation obtained by the opening of a window an inch. Injudicious application

may assume both extremes of directions, doing too much or too little.

The Brand bath has proved the most successful method of treating typhoid fever. The more nearly we approximate it, the more surely may we depend upon obtaining its grand therapeutic results. This has been acknowledged by Juergensen and others, and it is the personal experience of many, myself included.

In a letter received a few days ago from the venerable author of the Brand method, he writes: "Who reads what we write? Who acts upon it? No one. My typhoid treatment has proved this sufficiently now, after thirty years' labor, debate, discussion, and polemics, only a few know, the multitude knows not, what the aim of the Brand method is; they still confound it with the symptomatic method." These words from the man who has revolutionized typhoid treatment are indeed a sad commentary. They truthfully depict the present state of knowledge on this subject. In this city there are only three hospitals in which the Brand method is correctly applied; in others it is modified to suit personal predilections, irrespective of the fact that its results cannot be any more fairly judged by such modification than the rules of antisepsis in surgery can be judged if some essential of cleanliness be omitted.

The rationale of the bath is so simple that it appeals to our best judgment at once. We have an overwhelming of the nerve-centres by the products of infection. The shock and subsequent stimulus to the cutaneous surfaces are conveyed to the nerve-centres, and thence reflected to the heart, lungs, and other organs. Observation at the bedside at once renders these effects patent. The first effect is a refreshment, an enlivenment of the cerebrum. The eyes are opened; the face loses its apathetic stare; consciousness returns after one or more baths: the inspiration is deepened; expectoration is facilitated: the widening of the peripheral vessels and the stimulation of their coats relieve the heart; blood-pressure is increased; and the laboring organ becomes as quiet as does a sea-tossed ship in the hands of a skilled mariner. The secreting glands are aroused to activity. Moreover the temperature is reduced, not so violently as by medicinal agents, but more definitely, more in accord with normal tendencies. In brief, all the manifestations of the disease are favorably influenced because the normal standard is slowly but steadily and lastingly approximated under the influence of repeated judicious bathing. Even the exacting demands of the most recent ideas are met by this treatment. Mentchnikoff has shown, by his interesting studies, that inflammation is the phagocytic reaction of the organism to an irritant." Cells are phagocytes, hungry to devour any toxine or microbe that may find entrance into the blood. We may successfully aid the system in this "reaction against toxines" by endowing its main vitalizing agent, the nerve-centres, with vigor, by furthering elimination from the skin and kidneys, by removing hyperæmia of the organs, and facilitating the passage of phagocytes into the tissues: but more especially by rendering the blood more alkaline, and thus more favorable to the phagocytes.

All these are accomplished, according to well-established experiments, by the cold bath treatment. It has been recently shown by Thayer, in the Johns Hopkins laboratory, that the leucocytes are more than doubled after a Brand bath. On the other hand, the destructive effect of medicinal antipyretics on the leucocytes, their inhibition of excretion of products of tissue-change, and their effect on the heart have been again and again demonstrated.

Here we have an obvious illustration of the action of medicinal remedies and physiological remedies in a very common acute disease. The same observation may be made in all acute diseases, while in those of short duration and characterized by absence of serious depreciating tendencies, medicinal agents are more useful chiefly because more agreeable and practicable than baths, the latter are far superior in all those acute maladies which endanger life. Baths, though unpleasant to the patient and friends absolutely give sustenance to the crippled organs which are struggling to maintain life, while medicinal agents, though agreeable to patient and friends, serve only to enfeeble the heart, cripple the kidneys, and thus aid the disease rather than the patient.

In chronic diseases the difference in effect of medicinal and physiological remedies is no less striking. If such diseases are attacked ere serious organic degeneration has ensued, the most threatening and subsequently incurable diseases become amenable to treatment. Even when these are advanced, good results may be expected. I can affirm, from personal observation, the statement of the great Neapolitan clinician, Semmola, who says: "The methodical, internal, and external application of water, modified in temperature as required. together with climate, an appropriate diet, muscular exercise, etc., are aids by which hydrotherapy excites cutaneous activity and, with it, all functions of tissue changes and organic purification, so that by these means often real marvels of restoration in severe and desperate cases may be accomplished." The reports of the Montefiore Home for Incurables, and my papers read before the State and County Medical Societies, contain clinical proofs of the correctness of this apparently enthusiastic view. Cases of intractable anæmia, dyspepsia, angina pectoris, Bright's disease, diabetes, phthisis, and epilepsy are recorded, which have been under observation by Drs. Gaillard Thomas, Janeway, A. H. Smith, Jacoby, and others, the results of which justify Professor Semmola's claim.

It is not my purpose, however, so much to dwell upon these results as to afford illustrations of the superiority of these hygienic or physiological measures over the medicinal agents. Let us take as an example, for this purpose, chlorosis. I have chosen this chronic affection because it is as well or perhaps as poorly understood as any other, but more especially because, in its treatment, one medicinal agent, iron, has long been regarded as almost a specific. Chronic diseases do not, like the acute forms, tend to spontaneous recovery. Chiefly because patients affected by them are not, as they are in acute diseases, forced to be removed from their etiological agencies, and they are not, as in acute disease, usually subjected to physiological remedies A patient suffering from typhoid fever or scarlatina is withdrawn from the source of his infection; he is placed at rest and secluded—good air, proper diet, etc., are usually afforded him as a matter of course. A young woman suffering from anæmia usually remains within the sphere of the etiological factor of her disease: while the doctor attempts, by iron, food, etc., to reconstruct the blood, which is unhappily regarded as the chief point of attack.

There can be no doubt in the mind of any practical observer, that the same care that is given (perforce) in typhoid fever to the removal of the patient from his unfavorable environment would, if afforded the chlorotic girl, conduce far more to her recovery than the faithful dosing with iron in any of its more or less vaunted forms. Who has not seen a pallid school-girl, who had been for months dosed in vain with Blaud pills, regain her ruddy color, spirits, and appetite so soon as she was removed to the country, where she had access to unpolluted air, water, and food; where she was allowed untrammelled movement of muscle and lung and heart? Hygienic remedies are as potent for good here as they are in typhoid fever. Many of the latter recover under the expectant or medicinal treatment, more recover under a rational application of physiological remedies; many cases of chlorosis recover at home, even under unfavorable conditions and unphysiological treatment, more recover under the judicious use of exercise (rest, which is just as important), proper (not necessarily so-called strengthening) food, etc. Despite these patent facts, physicians continue to ply these unhappy patients with drugs whose reputation rests upon a purely empirical basis. The abuse of iron in anæmia is a crying shame, when it is considered that the quan-

tity in the entire human body amounts to about fifteen to forty-five grains, and that the greatest loss ever found in an anæmic patient was three to four grains, which one quarter pound of good beef would readily furnish. How much more rational is the removal of the patient into pure air, where the hunger of the oxygen-carrying hæmoglobin may be appeased. How much more rational than iron administration is the placing of an anæmic seamstress (?) into a well-aired hospital ward, where good food, rest for her treadle-wearied limbs, baths, etc., could be methodically applied.

Allow me to urge a more methodical application of non-medicinal remedies. If there is any point upon which we are derelict as a class, it is the lack of precision in our prescription of remedial measures, especially those valuable non-medicinal agencies which, as Nothnagel and more recently Osler have shown, are coming to the front as chief remedies. While there is no lack of insistence upon the systematic administration of medicines, while the regulation teaspoonful doses three times daily, or powder every three hours, is swallowed with the utmost punctuality, the patient suffering from a chronic malady is allowed to drift along as best he may, taking his exercise, his diet, his rest, his bath, as pleases his sweet will or suits his personal convenience.

In this connection I cannot refrain from again referring to the neglect of the chief hygienic remedy in chronic disease—water. Its value in acute diseases is so recognized by some of the best teachers in this city and country that I may well leave its fate to the good seed annually sown by these earnest men. In chronic diseases, however, which are the bane of our lives and the opprobria of medicine, much missionary work is required to arouse a just appreciation of the great value of water as an auxiliary to other physiological remedies. Abroad this is no longer the case. The most prominent teachers and consultants constantly dwell upon and prescribe it. In this country a few men like Draper and Peterson have written upon it. The clinical results obtained by it abroad and at home surely entitle it to a more careful investigation. While electricity, whose clinical results are far inferior, is taught in our schools, there is not a single chair from which the principles of hydrotherapy are explained or its technique demonstrated. If one tithe of the interest manifested in new drugs, which in most instances benefit only the manufacturer and leave physician and patient deluded and disappointed, were devoted to the study and practice of hydrotherapy, our knowledge of this subject would be enriched and suffering humanity would rise up and call us blessed.

If I have referred more freely to the application of water in this connection, my reason lies in the fact that it is the most powerful agent among physiological remedies, both for evil and for good, and the least understood and appreciated by the profession. The extract from Dr. Brand's letter given above and the rare application of hydrotherapy in chronic diseases testify to the truth of this proposition.

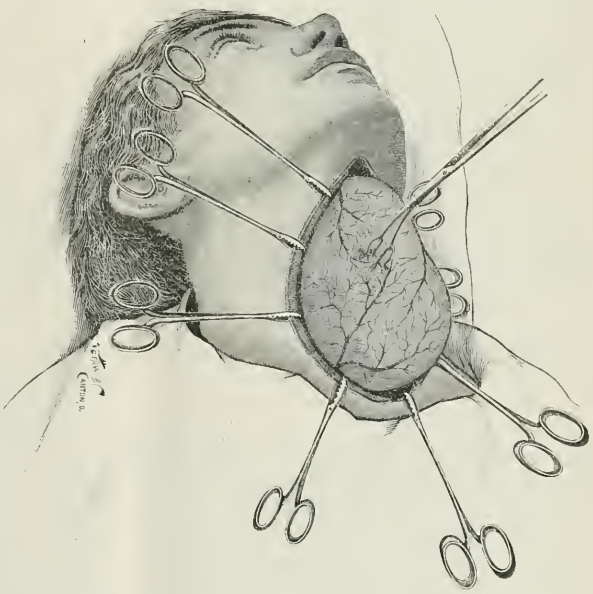
Though the modern physician claims to have emancipated himself from dogma and the schools, he is enslaved by the drug-prescribing habit. Drugs are to-day presented in alluring forms and rapid succession; they come to us not with the sounding of trumpets but with the insidious claims of a few clinical tests of Professor So-and-so and Private Docent So-and-so. Often we are not even vouchsafed information as to their method of manufacture. If their composition is given, it is in the new chemical nomenclature, which to most of us is absurdly incomprehensible. For instance, agathin, a new remedy extolled for neuralgia, is said to be the salicyl-alpha-methyl-phenyl-hydrazone; it is obtained by the interaction of salicylic-aldehyde and alpha methyl-phenyl-hydrazone.

I plead to night, not for the abolition of drugs, some of which I value as highly as anyone, but for a more methodical application of remedies like rest, exercise, diet, water, and proper environment—remedies which boast of greater antiquity than any medicinal agent, remedies which have demonstrated their value in all epochs of medical history and which to-day challenge the most searching investigation.

AN OPERATION UPON AN INTERESTING CASE OF CYSTIC DEGENERATION OF THE THYROID GLANDS, WITH A REPORT.

By J. S. PYLE, M.D.,
CANTON, O.

Clement N——, aged twenty-one, consulted me, about August 10th, as to the propriety of removing a large growth of eight years' standing from the anterior part of the neck. The patient's condition at this time was becoming rapidly dangerous, the breathing was labored and the voice markedly husky. Severe dyspnœa was excited upon the least exertion. Examination of the source of the trouble revealed the presence of an enormous new-



formation extending from the hyoid body above and disappearing into the thorax below. Its lateral boundaries corresponded to those of the neck. The growth was pressing heavily upon the trachea, which occasioned the labored breathing. The sternum in front prevented a forward expansion, and hence the cause of the pressure upon the trachea. The urgency of the symptoms made it necessary to decide upon its removal. The patient entered my private hospital September 1st, and was operated upon the same day. The thyroid origin of the growth was easily made out, but its real nature was not determined until after the beginning of the operation, which was found to be cystic, the degenerative changes apparently commencing in the isthmus and extending to both glands. As far as it was possible to make out, no glandular substance remained. The growth was surrounded by a dense capsule, which was opened and the contents shelled out without in any way rupturing the

walls of the cyst. The appearance of the tumor is shown in the accompanying illustration after it was released from behind the sternum and before the capsule was opened. The lower third of the growth was fully concealed by the thorax and rested in approximation to the arch of the aorta and apices of the lungs. The excision was commenced by a vertical incision in the medium line of the neck, cutting through the integument and deep fascia, and following the interval between the sternohyoid muscles until the covering of the growth was reached. At this time the patient's breathing became very difficult, and it was found necessary to release the tumor from its thoracic environments, which was done with the index-finger, and with complete relief to the patient. The capsule was now opened and the cyst stripped of its envelope. This occupied but a few minutes and was attended with but little hemorrhage. The operation could not be said to be difficult, but a thorough knowledge of all the important anatomical structures and great self-possession are the prerequisites of success. Oozing of blood continued for several hours, and the wound for this reason was not closed until hemorrhage had almost ceased. Owing to the deep pocket formed behind the sternum by the removal of the growth, a strip of gauze, soaked in carbolic solution, was placed in it and allowed to protrude through the lower angle of the wound, to empty the space of blood that would otherwise accumulate. With the drainage arranged in this manner the incised borders were approximated with silk sutures. Healing was immediate, and the case was discharged in two weeks entirely recovered. The points of interest in this case are of physiological significance. No glandular substance could be found, and yet the patient showed no sign of abnormal nutritive changes, which is so characteristic of other cases that have been reported. His body appeared well nourished, but the color of the skin was strikingly sallow. The gland had undoubtedly not been functionating for a long time. The question which arises is whether the capsule in any way compensated for the loss of the glandular substance, or does the age in this case have anything to do with the delay of the characteristic symptoms?

68 West Tuscarawas Street, September 25, 1893.

REPORT OF A CASE OF SYMPHYSEOTOMY.

By J. S. BROWN, M.D.,

MONTCLAIR, N. J.

ATTENDING SURGEON TO MOUNTAINSIDE HOSPITAL, MONTCLAIR, N. J.

Probably never before, in the history of operative obstetrics, has an operation been proposed which in the same period of time (about eighteen months) has attracted such general attention than has the revival of symphyseotomy. The reason is plain. Fœtal destruction is distasteful to all, and the thought of having destroyed human life, whether by craniotomy or by unusual traction made by forceps or version, leaves an impression of cruel and unscientific work. The following case is reported, not only because of the happy result and the aiding of statistics, but also because it well represents a class of cases, whose pelvic diameters have always been considered too great to admit of Cæsarean section, yet whose delivery by either forceps or version must surely prove disastrous to the child.

On the morning of September 8th, I was asked by Dr. L. W. Halsey to see in consultation Mrs. O——, aged twenty-five, white, United States; four feet ten and one-half inches in height, and of an average weight of one hundred and ten pounds. She had been pregnant on one previous occasion, and was delivered at term on April 2, 1892, of a dead child, weighing seven pounds, after a forceps delivery which amounted to a craniotomy, the head being crushed to such an extent that the eyes were pushed from their orbits. The present labor had been in progress about twenty hours—a midwife being in attendance. Dr. Halsey had been called about an hour before my arrival. The woman's general condition was pitiable—fully exhausted. Her face and eyes were œdematous from straining. The vulvæ were enormously swollen. The os œdematous, dark, and protruding. The latter condition caused by the pounding of the child's head against the lower uterine segment and pelvis. The membranes had ruptured. The head presented R. O. A. The pelvis was a generally contracted flat pelvis, with an antero-posterior diameter of three and one-quarter inches. I applied an Elliott forceps, and retracted os; but after repeated trials to make the head engage, I became satisfied that delivery with a living child by this means, or by version, was quite impossible, there being such a disproportion between head and pelvis. The child was still alive, the fœtal heart-sounds being distinctly heard. Symphyseotomy was decided upon as offering the best chances to both mother and child. The sacro-iliac joints were movable. The method of technique has been so often described that it is sufficient to state that the operation was done cleanly and the method of Morisani used. The subpubic ligament was left intact. It is worthy of mention, however, that the incision was made with one stroke of the knife, no dissection being used, and the fibres of the pyramidalis were but slightly separated. The forceps had been left upon the child's head, and a sterilized towel wrapped around the handles. This latter procedure would seem to be an advantage when one was cramped for help, as then no time is lost in their application. The pelvis was now supported by Dr. Halsey, and much to my gratification, the head at once engaged and with good but gentle traction was delivered. Some little trouble was experienced in extracting the shoulders, the child being large and weighing immediately after birth ten pounds. The child was somewhat asphyxiated, but soon revived and cried lustily. The placenta was easily expressed. The parts were well cleansed, and tears of the vaginal wall due to over-distention looked for. One was found commencing in the vestibule to the left of the urethra, and running one inch inside of vagina, communicating above with the incision over symphysis. A suture passed just back of the rent, pulled the vaginal wall forward, and the rent was closed with a continuous suture of sterilized five-day gut. The incision over symphysis was closed by a layer of buried gut uniting all subcutaneous tissues down to bone, fine iron-dyed silk being used to unite the skin. The method of bandaging, while perhaps not new, was eminently satisfactory. An assistant grasping the trochanters and raising the patient from the bed, a strip of three-inch rubber plaster was run from one anterior-superior spine of ilium, around body over opposite trochanter. A similar piece was placed opposite, thus crossing over incision and holding the gauze dressing firmly in place. Over the rubber plaster, and in a similar manner, were run several layers of plaster-of-Paris bandage. The result being to place the pelvis in a case not easily soiled, and one that could be depended upon to keep the bones in apposition. A catheter was tied in the bladder and the parts disturbed as little as possible for the first three days. The nurse had no trouble in keeping the patient clean, being able to raise her without injury. The case did nicely, the temperature reaching its highest point on the evening of the third day, 100⅘° F., then falling to normal and remaining there. The stitches were removed from the incision over symphysis on the seventh day. Primary union was secured throughout. The vaginal tear was also examined at this time, and found completely closed. The patient sat up on the twenty-first day, and walked on the twenty-sixth. Strange to say, the patient showed few signs of weakness from her long confinement in bed. There was no so-called waddling gait. The symphysis seems firmly united. The child continues to thrive, and is a well-nourished baby-boy.

In an interesting and instructive article in the *Medical News* of August 5th, Dr. Robert P. Harris reports twenty-five similar operations in the United States. I

have been able to find reported since, one. Four mothers have died, and seven children have been lost. Four, stillborn. The other three have died from one to seventeen hours after birth. One from long head-pressure, one from meningeal hemorrhage, and one from injuries received during attempts to deliver. The cases which have proved fatal to mothers have been of such a desperate character when the operations were performed, that, judging from the reported histories, one would expect two to die, no matter how treated, while the third and fourth might have recovered, had sepsis not occurred in the symphysis of the third, and a double pneumonia from exposure in the fourth. The operation, taking all cases reported throughout the civilized world, gives a mortality far greater than does conservative Cæsarean section under antisepsis, as managed in the best maternities of Europe. Statistics are deceptive at their best, but to calculate the mortality in our own country on twenty-seven cases, would seem misleading, especially so when one considers that the best results have been obtained from operations performed early, before the patients were greatly exhausted. Unfortunately, most of the operations in the United States have been upon cases which have been seen late. This latter statement is true of my own case, and if a woman who has been thoroughly infected by a dirty midwife and allowed to remain in agony for many hours, till nature rebels, does not develop a septic metritis, it is because God is good.

October 9, 1893.

TREATMENT OF FRACTURES INVOLVING THE ELBOW-JOINT.[1]

By JAMES E. MOORE, M.D.,

MINNEAPOLIS, MINN.

So many bad results have followed these fractures in the past, that surgeons the world over have been somewhat inclined to accept of the situation and conclude that a very large percentage of bad results was unavoidable. The experience of our best surgeons of the present day, however, demonstrates that a good result is the rule, and that a poor result is the exception; and the exceptions are growing beautifully less from year to year.

The poor results are deformity and anchylosis. The fact that better results are being obtained now than formerly, goes to show that a large percentage of bad results was not a necessity, but was due to bad surgery. If foreign surgeons follow the instructions laid down in their books they must expect bad results. American surgeons, in this as in every other branch of mechanical surgery, have taken the lead.

The deformity in fractures involving the elbow is usually due to loss of the "carrying function," and this loss is due to a failure upon the part of the surgeon to place the arm in the proper position.

The laity, and unfortunately many doctors, do not seem to understand that a normal arm is crooked at the elbow when in extension. I have been consulted many times by persons who had accidentally discovered that they had crooked arms, and who seemed greatly surprised when informed that the Almighty makes arms that way. Writers upon anatomy and surgery have laid too little stress upon this "carrying function." It is best demonstrated by bringing the arms close to the trunk with the forearms extended and supinated. This wise provision of nature, which enables us to carry a heavy weight in each hand without interfering with locomotion, would seem to be a strong argument against our ever having walked upon "all fours." This function differs very much in different individuals, and many times there is a marked difference between the two arms of one individual. The angle is usually greatest in muscular persons, and least in women and children; although I have seen it very marked in women who had very large hips.

The indications for treatment in this class of fractures are just the same as in any other: viz., to place the fragments in proper position and hold them there. Much depends upon the first dressing. It is rarely necessary or advisable to make local applications to reduce the swelling or inflammation; in fact, much harm has resulted from delay in order that useless liniments and poultices might be applied. The fragments should be placed in proper position at the very earliest time possible. If reduction cannot be readily accomplished without an anæsthetic, one should be administered. In the vast majority of cases reduction can be readily accomplished by straightening the arm, and gently pushing the fragments into place with the fingers. Occasionally, in fractures of the lower end of the humerus, the fragments are so misplaced that they cannot be reduced by manipulation. In such cases they should be cut down upon, under proper aseptic precautions, and reduced through open wound. Having made an open wound to reduce the fragments, they should be wired. After reduction the arm should be compared with its fellow. The apices of the outer and inner condyle, and of the olecranon process, should form a straight line across the back of the arm when the forearm is extended. The distance between the point of the external condyle and the tip of the olecranon should be greater than between the last-mentioned point and the apex of the inner condyle.

The forearm should be extended and extension kept up by an assistant while the dressings are being applied; and just before the dressings are applied the arm should be compared with its fellow, in order to estimate the size of the angle between the arm and the forearm, or, in other words, to see that the "carrying function" is properly preserved. The dressings should be applied ordinarily with the forearm extended. There are exceptional cases, however, where the fragments can be controlled better with the elbow flexed. Within the past year I treated a case for Dr. Beard, in which I could not keep the inner condyle in position with the elbow extended.

I advise the straight position because I believe that in the majority of cases the fragments can be controlled best in this position, and because the "carrying function" can be preserved. The most unsightly deformities following these fractures are due to the loss of the "carrying function," and these cases have usually been treated in the flexed position. When the arm is flexed it is very difficult to tell whether this function is preserved or not. The majority of fractures involving the elbow-joint have been treated in the flexed position, not because the fragments could be held better or because deformity could be prevented, but for the sole reason that the surgeon feared anchylosis, he very properly claiming that if anchylosis should follow it would be better to have it in a flexed position. With good treatment anchylosis will very rarely follow, and even if it should occur with the arm straight, it is a comparatively simple matter to put a crook in it.

The parts having been properly placed and the dressings applied, the arm should be kept at rest for four or five weeks, or until union is complete. In other words, the passive motion should not be employed until union is complete and all dressings removed. I have followed this plan for years, and find that passive motion is rarely called for even after the dressings are removed, because motion is quite free and the natural use of the arm is the very best kind of motion for it.

This "anchylophobia," that has prevailed in the profession for so long, is responsible for much bad surgery. It is not only responsible for the treatment of elbow fractures in the flexed position, causing deformities that might otherwise have been prevented, but it is responsible for much meddlesome surgery called passive motion, which in its turn has many times caused arthritis, and consequent anchylosis. As a rule, it is not the fracture *per se* that causes anchylosis, but the amount of inflammation following the injury. Now, if there is any one thing well-established among orthopedists and those having large experience in the treatment of inflamed joints, it is that absolute rest is the best treatment. Rest

[1] Read before the Hennepin County Medical Society, October 2, 1893.

never causes anchylosis. I have very often kept healthy joints at rest for months, and have never seen anchylosis follow. I have kept inflamed joints at rest for years and seen them get well with some motion. Of the many anchylosed joints coming to me following fractures, I believe that most of them have been due to ill-advised passive motion rather than to the injury. These cases almost invariably give the history of prolonged torture from passive motion. As a means of overcoming existing anchylosis, passive motion is very valuable, but as a means of prevention, I am very sure it has done more harm than good.

While I emphatically denounce unnecessary interference with a joint fracture, I am just as emphatic in asserting that it is necessary to change the dressings from time to time owing to circumstances, particularly during the first two weeks. Whether there is much swelling or not, the size of the arm will vary, so that a dressing which fits nicely and holds the fragments perfectly when first applied, may be a bad fit and fail to hold the fragments after a few days. Any material that will hold the parts properly may be used as a splint.

My preference is for plaster-of-Paris, because it meets the indications so beautifully; because it stays where you put it, and because a restless patient or meddlesome friends cannot misplace it.

After union is complete, if I find free motion, even if limited, I do not employ passive motion, but advise the patient to begin using the arm at once. When motion is not free, or when it is very limited in extent, I employ passive motion for a few times, until a certain amount of free motion is present, which is gradually increasing, after which I am content to depend upon the use of the arm to restore the joint to its normal condition.

I wish to mention fracture of the olecranon very briefly, just to demonstrate the inconsistency of the advocates of passive motion. We all agree that extension is the only position in which this fracture should be treated, because it is the only one in which the fragments can be approximated. Passive motion is seldom attempted here, even by its most enthusiastic advocates, because of the danger of interference with union; or if it is advised, it is not until union is quite well advanced, when the joint has so far recovered from the injury that motion does not injure it. We do not expect, nor do we get, anchylosis after this fracture, and one very important reason why we do not get it is that, instead of fearing anchylosis, we fear non-union, and are therefore content to work a cure without interference.

Allow me to ask in conclusion if it would not be better for our patients and for ourselves, if we had some such wholesome fear concerning other fractures of the elbow?

The best article I have read upon this subject was written by John B. Roberts, and appeared in the *Annals of Surgery*, May, 1892.

Thyroid Therapy for Psoriasis.—Struck by the remarkable improvement observed in the condition of the skin in cases of myxœdema treated by the administration of thyroid extract, Dr. Byron Bramwell, of Edinburgh, was led to try the same agent in the treatment of some chronic and obstinate cases of psoriasis, with results that were at once surprising and gratifying, as detailed at the recent meeting of the British Medical Association. A preparation of thyroid gland was the only medicament given, so that the possibility of doubt was practically eliminated. In some cases the subjective improvement was immediate, and was soon followed by objective evidence of improvement. The inflammatory redness of the diseased areas diminished, and there was considerable desquamation. One patient was made worse; in two the treatment was followed by no benefit; and in one case a slight relapse took place. The question at once suggests itself that if this method of treatment prove ultimately successful in psoriasis, why should it not be applicable to other diseases of the skin as well.

INFLAMMATION OF UPPER AIR-PASSAGES AND EARS CAUSED BY INHALATION OF PERSIAN INSECT POWDER.

By WILLIAM PHILIP SPRATLING, M.D.,
NEW YORK.

My attention was recently called to a family of three persons suffering from marked nasal catarrh and sore throat. In one case the trouble, which had commenced in the nose and throat, had extended along the Eustachian tubes and caused painful swelling, that involved, first the left and subsequently the right, internal and middle ears. The trouble in all three cases began immediately after exposure to the fine dust of Persian insect powder that had been freely used about the premises for the purpose of destroying water-bugs and roaches. The first symptoms noticed were a feeling of roughness and discomfort in the throat, a constant irritation that provoked cough, and a sensation of fulness about the nose. One of the persons, a young girl of seventeen, who suffered from asthma in a mild form, suffered most from the immediate effects. Her asthmatic breathing, never so loud that it could be heard across a small room, became so greatly exaggerated as to be heard from any part of the house. In one of the other cases the trouble extended along the Eustachian tube and set up a violent inflammation that involved the left internal and middle ear, and later on the parts above the ear. The side of the face became swollen and tender to touch. Three days after the trouble had reached its height in the left ear, the right began to pass through the same process. This person had been troubled for some years with double chronic otitis media. The third person, immediately after inhaling the powder, experienced considerable irritation about the throat, and later on nasal catarrh, ringing in the ears, and considerable deafness. These symptoms lasted three days, when improvement began, and shortly ended in complete recovery. In the case in which the ears were inflamed, no improvement was manifest before the end of a week. Intense pain was constantly present, and nothing would in any degree relieve it, except morphia hypodermatically. Swelling occluded both auditory canals. I report these cases for the reason that the cause of the trouble is unique. Persian insect powder is made from a plant that grows in Europe and resembles the large white American daisy. The insect powder made from it is essentially a pollen; and it would seem a wise thing to caution such persons as those who are subject to hay fever, especially, against being in the immediate locality when it is being used.

70 WEST EIGHTY-EIGHTH STREET.

COMPLETE BURIAL OF A RING BENEATH THE SKIN OF THE FINGER.

By JAMES J. CONCANON, M.D.,
NEW YORK.

THIS curious case presented itself in my class at the Northwestern Dispensary, October 10th.

While treating a child, I observed that one of the fingers of her grandmother's right hand was considerably swollen around the first phalanx, a small point of granulation-tissue protruding about an inch from the knuckle.

Examination showed a narrow cicatrix extending around the finger, while a hard mass, suggestive of annular productive ostitis, could be felt beneath the skin. The uniform size and shape of the mass, as well as its very slight mobility, soon suggested what it was—an imbedded ring.

The woman (Mrs. K——, aged sixty) stated that it was a chased gold ring of the band pattern. She had put it on about nine months ago. When worn for a month, the surrounding tissues became swollen and sore. The ring was not removed, but at the end of another month

was completely imbedded and covered over by healthy skin, so that only a slight scar marked its site.

Apart from the slight œdema the finger is in good condition, there being no pain or impairment of joints. The case proved an interesting diagnostic study for the staff. The woman refuses to have the ring removed, as it gives her no trouble.

CEREBELLAR SYPHILOMA.

By CHARLES E. NAMMACK, M.D.,

NEW YORK.

ATTENDING PHYSICIAN NEW YORK HOSPITAL, OUT-PATIENT DEPARTMENT; VISITING PHYSICIAN GOUVERNEUR HOSPITAL.

SYPHILOMATA are rarely met with in the cerebellum, according to Gowers (vol. ii., p. 493). The following case may therefore be worthy of record, especially as the localizing was unusually clear, and as the results of treatment seem to establish the nature of the lesion.

Daniel M——, forty-four years of age, cabinetmaker, came to my office on September 1st, complaining of dizziness, occasional vomiting, unsteadiness in walking, double vision, and bilateral occipital headache. He also stated that he had "machinery" noises in the left ear, and thought that his left-hand grasp had become weaker. These symptoms had existed about a month, and were progressive.

His previous history was that of a sober, temperate man. He had "muscular rheumatism" at times, but never had acute articular attacks. He absolutely denied ever having had syphilis, but cross-examination disclosed the fact that fourteen years ago he had an "ulcerated" throat, and was informed that he needed medicine to "drive the disease out." When an eruption subsequently appeared upon his body, he assumed that the disease had come out, and discontinued treatment. He has never had a convulsion.

On examination, the scalp was not found to be sensitive to tapping or pressure. The watch could not be heard on contact with left ear. Both drumheads appeared to be normal. Tuning-fork heard best on unaffected side. Diplopia is manifest in the left eye, one image being below and to the left of the other, and nystagmus is evident. Dr. Leroy Pope Walker examined with the ophthalmoscope and found absolutely no sign of optic neuritis, blood-vessels normal in size, no tortuosity, no swelling of disks, outlines clear and distinct. Dr. Walker's further report is as follows: O. D., hyperopia = 1.50 D. with 0.75 D. vertical astigmatism. Vision uncorrected = $\frac{2}{10}$; with proper correction, V. = $\frac{20}{20}$ +. O. S., hyperopia = 2.50 D. with 0.75 D. vertical astigmatism. Vision uncorrected = $\frac{2}{200}$ +; with proper glasses, V. = $\frac{20}{30}$ +. Fields and color perception normal.

In standing, the patient keeps the feet widely separated, and has a tendency to fall toward the right side. On walking, he presents the characteristic titubating gait, and his reputation for sobriety has suffered thereby. There is no inco-ordination in the upper extremities, nor in the lower extremities when patient lies supine. The knee-jerks are exaggerated.

The diagnosis is therefore syphilitic neoplasm in left cerebellar hemisphere, with pressure on abducens and auditory nerves. The treatment ordered was iodide of potassium, grs. x. t.i.d., to be increased five grains every third day until grs. lx. t.i.d. had been taken. Five weeks later, patient reports that his dizziness, headache, and double sight have disappeared. He has resumed work and discarded his canes. There is still ataxia, nystagmus, and exaggerated knee-jerks. Dr. M. Allen Starr very kindly examined the patient for me to-day and confirmed the diagnosis.

29 EAST TWENTY-FOURTH STREET.

Gelsemium for Lumbago —Ten drops of gelsemium every four hours will relieve the pains of lumbago.

Progress of Medical Science.

Insanity following Infectious Disease. — An abstract of the report made by Regis and Chevalier-Lavaure, presented to the *Congrès des médicins aliénistes des pays de langue française*, is to be found in the *Mercredi médical*, August 9, 1893. Insanity following infectious disease is a consequence, direct or indirect, of some special intoxication. In form it is a primary mental confusion, or a confusional insanity. Seglas sums up the concensus of contemporary opinion in the following: "Primary mental confusion is an expression of nervous prostration, and appears to have an individual etiology. Without absolutely rejecting predisposition, this factor often exists in a minimum degree, the exciting cause being in general the most powerful influence. The most frequent exciting causes of confusional insanity are trauma, moral or physical, accidental or surgical; infectious diseases, as puerperal fever, typhoid fever, cholera, grip, etc.; and disorders of nutrition." Infection or auto infection is in many cases the only possible assignable cause for the mental state, though at present its exact influence is unknown. On general principles, gastro-intestinal antisepsis, the regulation of different bodily functions, improvement of nutrition, and appropriate therapeutic measures, constitutes rational treatment, however diverse the mental troubles to which primary confusion may seem closely allied.

In confusional insanity there is a premonitory stage that may last several hours or several months. There is change in character, irritability, loss of sleep, and great anxiety. The onset is generally abrupt, accompanied by extreme excitement that suggests acute mania with complete unconsciousness of surroundings. Sometimes the onset is gradual, resembling in character a condition of subacute alcoholism. There may be a marked degree of stupor, with or without cataleptiform phenomena. The course of the disease may be continuous, remittent, or paroxysmal; but usually there is a mixture of excitement, calm, stupidity, and stupor, that varies in duration and often presents intervals of relative lucidity. Its duration varies, ranging from a few days to several months, and possibly several years. Thus it will be perceived that there are acute, subacute, and chronic cases. The termination of the disease is as follows: Recovery, preceded by a long or short stage of more or less psychic exhaustion, with complete loss of memory concerning the time and duration of the disease; recovery, with slight impairment of the mental faculties; chronic state of dementia, with periods of excitement and of stupor; death, following an acute or chronic course of the disease, and usually due to pneumonia, marasmus, or acute delirium. The pathological changes are states of anæmia, cerebral œdema, and meningeal abnormity, which prompts Willi to consider mental confusion a form of psychic disturbance that holds a middle ground between purely functional insanities, like mania, melancholia, and paranœa, and the insanities of organic changes. Meynert gives a long description of characteristic psychic manifestations. Attention, perception, apperception are weakened, resulting in loss of consciousness for time, place, and personalities. Language is often totally incomprehensible, and may or may not have reference to the patient's thoughts. Emotion is enfeebled, and follows the course of the disease. Ideas present themselves as in a dream, and may or may not be accompanied by hallucinations and delusions that do or do not influence conduct. Confusional insanity is more serious as regards prognosis than mania or melancholia. It is about as frequent as these two conditions. Heredity plays a less important part than in other mental diseases. Rachitis and all abnormal states that weaken the nervous system or the organism in general during the period of development, are factors of moment in the history of mental confusion. Meynert considers a powerful influence in its production

to arise from a defect of parallelism in the development of the nervous system and the development of the circulatory system.

Ununited Fracture in Children.—Dr. Power says ununited fractures of the long bones in children are rather uncommon. Of 150 cases of fracture reported by Norris, only 1 was found; of 484 cases reported by Gurit only 14 were found; of 685 cases reported by Agnew, only 28 were found. The author divides all cases of ununited fracture into three classes: 1, those fractures produced in utero or immediately after birth; 2, those produced by slight traumatism; 3, those resulting from osteotomies. Spontaneous fracture is very uncommon in children. An analysis of 72 cases showed there were 6 of the clavicle, 7 of the arm, 12 of the thigh, and 45 of the leg. In 21 cases there was subsequent consolidation; 4 were improved, and 45 remained ununited.

Anuria for Eleven Days, with Recovery.—Dr. Düring has reported a case of a man, sixty years of age, who had suffered for a number of years from gout and renal colic, the urine at times containing small calculi. On one occasion the man was seized with severe pain in the left loin and in the course of the left ureter. The testicle of the same side was retracted. A few drops of urine were passed from time to time at long intervals. There was also vomiting. From this time no urine was passed, despite the efforts of the patient. The bladder was found to be empty. Warm baths, douches, massage, and diuretics were employed, but without avail. On the third day uremic symptoms appeared: vomiting, eructations, somnolence, depression, restlessness, thirst, anorexia. In a short time copious diarrhœa set in. On the eighth day the man's condition became alarming, the uremic symptoms becoming more pronounced. This condition continued until the eleventh day, when, while straining at stool, a large amount of bloody urine was passed by the urethra. The urine was not preserved and a possible calculus could not be looked for. During the first ten or eleven hours between twelve and fifteen quarts of urine were passed. The threatening symptoms at once subsided, and in the course of forty-eight hours the patient felt as well as usual.—*Medical News.*

On the Treatment of Bronchiectasis.—Stewart says that while the generally accepted theory is, that bronchial dilatations are produced by the contraction of fibrous tissue in the lungs, that process does not explain many, and, indeed, the most typical examples of the disease. For bronchiectasis is often present when there is no cirrhosis, and in not a few cases the fibroid change follows upon it as a secondary consequence. Further observations have confirmed the views which he expressed twenty-six years ago, that an atrophic process in the walls of the bronchial tubes affords the real explanation, and that, given such an atrophy, the pressure of the air in the respiratory tract leads to dilatation of the tubes, while the consequent accumulation and decomposition of the mucus produce further changes characteristic of the disease. He has therefore endeavored to adopt treatment which would meet these conditions. Very little, however, can be done to prevent the occurrence of atrophy, nor, except by keeping down cough so far as that was warrantable, to interfere with the pressure of conditions which tend to dilate the weakened walls. The constant aim has been, therefore, to prevent the decomposition of the sputum and its consequences. Turpentine, creasote, carbolic acid, salol, and other antiseptics by the stomach, as well as sprays and vapors of various kinds, have all been sedulously tried with, on the whole, a very limited and temporary advantage. In one case during the past winter he had used an intratracheal injection of menthol (10 parts), guaiacol (2 parts), and olive-oil (88 parts), a drachm being injected into the trachea twice daily. The injections were given regularly for about a month, and then gradually less frequently, with the result that in a week the fetor of the breath and sputum had entirely gone. The temperature speedily fell to normal, the general symptoms disappeared, the weight increased, the appetite returned, and the digestive process became established, while the pulmonary signs had been favorably modified. Had this treatment failed Stewart proposed to try operative interference, and gives details of a case under his care several years ago in which such treatment was adopted with good result.—*British Medical Journal.*

Granular Lids.—In the *Archives d'Ophthalmologie*, April, 1893, Dr. A. Trousseau reviews the subject of surgical and mechanical treatment of granulations of the conjunctiva. Several questions are asked and answered concerning the methods of Davies and Abadie. Is the treatment dangerous? No; though serious accidents may follow. Is the treatment inconvenient? Certainly; its sequences last from four to six weeks, and the patient always does well to remain in the hospital for a month. Does treatment radically cure the granulations? Not in the most serious forms; in average cases, yes. Caustics and mechanical procedures must supplement this treatment in severe cases. Surgical treatment alone can secure recovery. It relieves the granulations, but does not cure at once. Without supplementary treatment relapses always occur. For average cases two methods are recommended: rubbing with pumice-stone dipped in sublimate, and rubbing with cotton dipped in the same solution. These may be alternated with the sulphate-of-copper treatment.

Sodium Bicarbonate in Large Doses.—In the *Revue générale de Clinique et de Thérapeutique*, March, 1893, is given some observations on what Huchard calls heroic alkaline treatment. This consists in the administration of two drachms to ten drachms daily of sodium bicarbonate, in successive doses, in conditions of hyperacidity of the stomach sometimes present in diabetes, in the gastric crises of tabes, in cardiac disease with acidity of the stomach, in diseases of the liver, and sometimes when gall-stones have formed. A case is recorded of incipient diabetic coma warded off by ten drachms daily of bicarbonate of soda.

Movable Kidney with Hydronephrosis.—In the *International Medical Magazine*, August, 1893, Dr. D. W. Graham gives the following conclusions as results of observation concerning this condition: Intermittent hydronephrosis is a frequent sequel of movable kidney. Mental disquietude may be the only symptom of a movable kidney or hydronephrosis. On the other hand, there may be functional disturbance of every neighboring organ. Disturbance of the function of the kidney may be less marked than that of the other organs. Hydronephrosis is a progressively destructive condition. Nephorrhaphy is indicated as a preventive measure even when not called for by the severity of the symptoms *per se*. Hydronephrosis once developed is most effectually and safely treated by lumbar nephrotomy and drainage. Nephrectomy is not warranted unless the kidney substance is completely destroyed or the ureter is impervious.

Growing Pains.—Karewski, of Berlin, has recently made a study of so-called growing pains, and finds that usually they have nothing whatever to do with growth. As a rule they are not seated in the bones, but about the muscles, and are similar to the pains of slight apyretic attacks of rheumatism. Such cases should be referred to their proper cause. Sometimes, however, in other cases there is a mild increase of temperature and more or less dull aching pain about the long bones. These occur in children who have been growing tall with undue rapidity. Karewski thinks that possibly active bodily exercise at this period has in some way irritated the epiphyseal lines of the long bones, and that this irritation has resulted in rapid proliferation and growth. When this condition is extreme, there is mild inflammatory action, with pain and abnormally rapid growth. Hence the natural inference that children have pain and fever not because they are growing too fast, but because they are really ill.

Extension of Gonorrhœal Infection in Women.—Dr. F. B. Robinson states that the course of the spread of gonorrhœa in women is mainly along the cylindrical epithelium. First, the gonococcus infects the urethra and the vulvo-vaginal glands; then the endometrium suffers, as it is cylindrical epithelium; next, the cylindrical epithelium of the endo-salpinx is involved; fourth, the germinal epithelium (cylindrical) of the ovary becomes affected; and, fifth, the gonorrhœal infection spreads into the membrane granulosa (cylindrical epithelium) and ovarian cystic degeneration occurs. It may require years to produce pus in an ovary from gonorrhœa. When the tubes are inflamed from gonorrhœa the patient gets better, but she does not entirely recover. There are recurrences of the inflammation, and the diseased tubes are best removed. Keating, who has an abstract of Robinson's paper in the *International Medical Magazine*, July, 1893, calls to mind the interesting fact that many cases of latent gonorrhœa in married women are rendered more acute and productive of future trouble by the pregnant state, thus accounting, probably, for cases of post-partum tubal disease.

Syphilis as an Infectious Disease.—The following views on syphilis, Dr. H. J. Klotz gives in the *Journal of Cutaneous and Genito-urinary Diseases*, August, 1893. Syphilis is caused by a micro-organism similar to those of the acute exanthemata. Primary and secondary local manifestations are due to the direct influence of this parasite. Its presence in these lesions is proved by their contagiousness. The general symptoms accompanying the stages and immunity are the result of the actions of toxines. The micro-organisms, under the influence of their own chemical products or under the influence of treatment, or in consequence of their own innate character, are either eliminated, or become extinct, or undergo some modification, or produce a new kind or species of micro-organism. This secondary parasite, which is similar to the bacillus of tuberculosis, can indefinitely remain in the organism, in a dormant condition, until called into activity by some accidental irritation. Accidental irritation produces the tertiary (gummatous) manifestations; but not the visceral affections, like tabes, general paralysis, etc., which are the result of intoxication with the toxines of the primary parasite. The secondary micro-organism is inoculable, like the bacillus tuberculosis, and produces lesions identical with the tertiary syphilis, but not primary syphilis. Tertiary syphilitic manifestations may, therefore, be due to direct inoculation without the necessity of a primary or a secondary stage.

Jaundice from Mental Emotion.—The existence of jaundice from mental perturbation was recognized by the older pathologists. Budd, in 1844, referred it to arrest of the secretion and retention of the bile in the blood. The theory of arrested secretion was abandoned when more correct notions of the physiology of the bile were acquired, and subsequently jaundice by nervous influence was ascribed to spasm of the bile-ducts; this, it was affirmed, might produce complete obstruction to the passage of the bile and consequent reabsorption. Frerichs, later on, recognized the occasional occurrence of this form of jaundice, which may appear very suddenly or in the course of a few hours after a violent mental emotion, as vexation, anger, fright, and he thinks that it may come about in two ways: 1. By interruptions to the circulation of the blood through the liver, arising from the influence exerted by the nerves over the calibre of the branches of the portal vein. 2. By interruptions to the heart's action, the respiratory movements, and the renal secretion.

Talamon, in a recent number of the *Médicine Moderne* (August 23, 1893), takes up the subject in connection with a remarkable case which had lately come under his observation, where a healthy woman, aged twenty-four, having had a severe fright, became intensely jaundiced after five hours. The icterus lasted twenty-four days. Talamon, in discussing the pathogeny of emotional jaundice, thinks that there are two objections to the current notion that it is due to spasm of the bile-ducts: 1, the suddenness of its production; and, 2, its persistence. With regard to the suddenness, there are cases on record where the jaundice has come on almost instantaneously. Villermé mentions a case where two young persons quarrelled and drew their swords; one of them suddenly became yellow, and the other, terrified at the change of color, dropped his weapon. The same writer relates another case of an abbé who suddenly became yellow on a mad dog rushing against him. Although statements of this nature may appear doubtful, still there are numerous observations which prove that under such circumstances as those alluded to, jaundice may be developed in a much shorter space of time than is wont to happen after the application of a ligature to the common bile-duct. The experiments of Tiedmann and Gmelin show that bile-pigment does not appear in the urine till forty eight hours after the ligation of the choledochus; those of Audigé, that resorption of bile is not effected under thirty-six hours. As to the persistence, it does not seem likely that a spasm of the bile-ducts can continue eight, ten, or fifteen days without relaxation. In Talamon's patient the urine was loaded with bile-pigment on the fifteenth day.

The theory of polycholia (Grisolle) does not alone explain the jaundice that follows mental perturbation, for the resorption is still to be accounted for. Talamon thinks that the principal element in the pathogeny of this form of jaundice is the disturbance through nervous shock of the hepatic cell whose secretory function is augmented, while at the same time it loses its property of retaining the bile which is formed, whence the immediate diffusion in the blood of the excess of bile secreted. This is, in fact, Liebermeister's explanation, who calls this emotional icterus a *cachectic* jaundice. In the normal state, he says, the liver-cells retain in their protoplasm the formed bile, a property which they lose in certain morbid conditions, leaving their product of secretion to diffuse itself through the blood as lymph. There is at the same time augmentation of the absorbent surface by reason of sudden paralytic dilatation of the hepatic capillaries. This, however, only in part explains the retention of the bile, and here Talamon assumes the existence of disordered contractions of the bile-ducts extending to the choledochus. This only partially interrupts the passage of bile into the intestine, for the spasm is not continuous, and there are periods when the bile passes freely, as when the stools are deeply colored. In the case which he reports, this fact is strikingly apparent in the clinical record; the stools were clay-colored one day, and bilious the next, etc. This is in accordance with the observations of Labadie-Lagrave, who has recently published a very complete treatise on "Diseases of the Liver." This kind of jaundice is clearly differentiated from most of the other varieties by the fact that the stools are not invariably and continuously decolorized. In a recent case of emotional icterus observed by Chauffard, the patient, after intense excitement, became jaundiced in the space of an hour; during the first five days the choledochus remained permeable, and the stools were colored and soft; the decolorization did not appear till subsequently. Labadie-Lagrave rejects the theory of spasm for these reasons, and also because histological investigation proves that the bile-ducts are very poorly provided with unstriped muscular fibres; faradization cannot efface the calibre of these ducts through their muscular fibres. He believes, with Chauffard, that if in this kind of jaundice there is any obstruction of the choledochus, this results from thickening of the bile, or from epithelial desquamation, as in simple catarrhal jaundice. It must be admitted that the mechanism of emotional icterus is not yet completely elucidated.—*The Boston Medical and Surgical Journal.*

The Operative Treatment of Peritoneal Tuberculosis.—The value of operation in the treatment of peritoneal tuberculosis in children has been much disputed, and even yet is by no means generally allowed. The nume-

rous cases benefited by laparotomy have been challenged as to correctness of diagnosis and the indications which predict a favorable result not thoroughly understood. The report by Conitzer of seven cases operated upon for tuberculosis of the peritoneum throws some light upon the points in dispute. The children varied from two and a quarter to nine years of age. Four cases were of the exudative form, in which there was a diffuse superficial inflammation of the peritoneum, with numerous very small tubercles upon the parietal and visceral membrane, and free serous fluid in the abdominal cavity. In all of these cases there was but slight disturbance of the general health. Some anorexia and heaviness and disinclination to move about were the chief symptoms. Some of the patients, too, had gray-colored stools, though not otherwise icteric. The other three cases were of the dry adhesive form, in which there was more general disturbance and often pain, and a considerable degree of matting together of the intestines and omentum. The operation consisted only of an incision into the abdomen, and, after allowing the free fluid to escape, closing up of the wound. No washing or manipulation of the cavity was done in any case. The four exudative cases all made a lasting recovery. In each microscopic examination of the tissue showed characteristic tubercular structure, giant-cells, and in two cases the presence of bacilli. The three other cases all showed caseous tubercular nodules with bacilli. One case recovered from the operation, and after four and a half months was still relieved from much of the pain and discomfort, though not at all well. The other two cases died with little or no relief.

After discussing these cases in detail he draws the following conclusions: 1. Peritoneal tuberculosis is spontaneously curable: the dry form in very few, the exudative form in a very large number of cases. 2. All forms may be cured or at least relieved by laparotomy, even when other treatment, including puncture, has failed. 3. The results of the operation depend upon (*a*) the form of the disease, the best results being obtained in the cases of effusion; (*b*) the duration of illness; (*c*) eventual complication. 4. The operation is contra-indicated in advanced cases or those with marked tuberculosis of other organs. 5. No explanation can be given of the reason or manner of the curative effect.—*Boston Medical and Surgical Journal.*

A British View of Germs.—According to the *Medical Press*, it seems that nothing less thorough than total abstention from food and drink can protect us from the imbibition of disease germs, inasmuch as there is not an article of daily consumption which will not harbor and propagate the bacilli in greater or less number. We cannot even eat a cabbage or other vegetable in the comfortable assurance that we are safe from infection, for it has recently been shown by Lominsky that the specific organizers of anthrax and typhoid and the staphyloccus pyogenes can exist for more than eighty days and multiply in plant tissues. After all, is not the germ craze getting rather wearisome? Is it worth while to trouble ourselves about 100 or 1,000 bacilli in a cabbage, when we know that we live from morning to night in a more or less thick fog of germs of all sorts?

Dangers Following Total Extirpation of the Uterus per Vaginam.—Dr. Jessett has pointed out the dangers following total extirpation of the uterus by the vaginal method. 1. Intestinal obstruction has occurred in several instances after vaginal hysterectomy, the result of adhesions of a loop of intestine to the edges of the wound through which the removal of the uterus was accomplished, causing distention and bending of the gut above the point of adhesion. All of the cases reported have proved fatal; in each, death appeared to be due primarily to exhaustion. 2. A second source of danger is met with chiefly in those cases in which the disease has extended somewhat laterally, from the risk of either dividing the ureters, or including them in the ligature, or forceps applied to the broad ligament to arrest hemorrhage. Several such cases are recorded. 3. Vesico-vaginal, or recto-vaginal, fistulæ are by no means so rare as might be supposed, after total extirpation of the uterus. Vesico-vaginal fistulæ are especially liable to occur in those cases in which the disease is somewhat extensive and the pelvis contracted, necessitating considerable force to enucleate the uterus. Often the opening is so high up that it is difficult to locate the exact seat of the urinary fistula, and in these cases the hope of closing the fistula must be very small. 4. Another source of danger is peritonitis, especially in those cases in which the parts are of necessity much dragged and torn. 5. Sepsis is answerable for many of the fatal cases. 6. Lastly, severe and even alarming hemorrhage often takes place.

Surgical Treatment of Fioroid Tumors.— Martin (*American Gynecological Journal*, May, 1893) groups the surgical procedures for the relief of fibroid tumors of the uterus under the following heads: 1. Removal of the ovaries to establish an early menopause. 2. Removal of the tumor per vaginam. 3. Removal of the tumor through an abdominal incision; (*a*) removal of the tumor without the uterus; (*b*) removal of the tumor with the uterus. The first method is adapted to that class of medium or small tumors where the growth is slow and the tumor is hard and symmetrical, and there is menorrhagia without metrorrhagia. Removal through the vagina can only be done when the tumor is not larger than a hen's egg. Unless the tumors are small and pedunculated, the operation is as liable to prove fatal as removal of the uterus; and if the tumors are large and more or less incorporated with the uterine walls, their removal leaves the uterus in an abnormal and mutilated condition, and should a portion of tumor be left it would continue to grow. As regards removal through abdominal incision, only occasionally is a tumor so situated that it can be removed separate from the uterus. The great majority of the cases require removal of the uterus together with the fibroid mass. Martin prefers in favorable cases to retain the cervix and treat the stump intra-peritoneally, because a stronger pelvic floor results, and the vagina is left in a better condition than if the cervix had been removed. Fixation of the stump in the abdominal wound is objectionable, as free dilatation of the bladder is thus interfered with and convalescence is prolonged. The author does not favor Byford's method.

Coma after Operation for Epilepsy.—The following case is related by Dr. Tiling. A youth aged seventeen had an epileptic attack eight days after an accident in which the lower part of his thigh was injured by a gunshot wound. After that there was a daily recurrence of the fits. Two operations were done. The first on the wound and the second for an abscess in the cicatrix. After the first operation the fits ceased for a brief period, and after the second operation for a year; but the fits returned, being accompanied by pain in the cicatrix, and a third operation was performed. This consisted in extirpation of the scar and excision of a piece of the thickened small saphenous nerve, and stretching of the sciatic and anterior cervical nerves. The curious thing about the case is that the patient did not awake from the narcosis, but remained comatose, being able to swallow, but unable to pass urine, which was drawn off. For twenty-four days he remained in this state, and five days later he was quite himself again, and the attacks have not recurred. A considerable difference of opinion was expressed in the discussion on the case, which was communicated to a medical society in St. Petersburg. It was regarded by some as a case of meningitis, while others argued the absence of signs of irritation and of paralysis as tending to disprove such a view.—*Neurologisches Centralblatt.*

The Diagnosis of Cholera.—Dr. G. Sherman Bigg, formerly Staff Surgeon, Allahabad, India, writes to the *Lancet* as follows: "The recognition of the fact that the presence or detection of the cholera bacillus is not a constant factor, reduces the diagnosis of cholera to that of an

ordinary disease. This result is a practical advantage, for bacteriological investigation, except as an aid in doubtful diagnosis, could not be relied upon to verify a disease in times of an epidemic. Furthermore, the diagnosis of cholera is exceedingly simple, for if there is one disease more than another in which the symptoms are characteristic of the complaint, that disease is essentially cholera. The very expression of the face invariably suffices to declare the true nature of the illness; but, coupled with the whispering voice, the violent cramps, the absence (not suppression) of urine, and the agonizing appeal for a long drink, a mistaken diagnosis is highly improbable. Cholera, when once seen, can never be forgotten (Dr. Fenwick), and if, instead of surrounding the disease with a halo of mystery, the simple method of relying for a diagnosis on the appreciation of the collective symptoms were adopted, an error of judgment would be rare, and medical men who have not had the opportunity of seeing a case of cholera would be ready to recognize the complaint with facility."

The Treatment of Obstruction of the Large Intestine by Temporary Typhlotomy.—Dr. Harrison Cripps remarks that unless the obstruction can be felt in the rectum, or some definite tumor be discovered in the abdomen, its exact site in the large gut cannot be determined. He advises in the first instance careful injections, with the view of possibly washing away an obstructing plug. If these fail to give relief, abdominal section is the last resort, the author recommending that in the first instance the incision should be made in the left inguinal region, between the umbilicus and the anterior superior spine. He related to the Harveian Society of London two cases in detail, in which he had found, after making the abdominal incision on the left side, that the sigmoid and descending colon were empty and collapsed. In each of these cases he closed the wound and opened the abdominal cavity on the right side over the cæcum. The parietal peritoneum was carefully stitched to the portion of the bowel in such a way that only a circular portion of the cæcum, no bigger than a dime, was exposed; through this an opening was made which gave immediate relief to a large quantity of air and liquid fæces. In both cases, after nine and thirteen days respectively, the stools appeared in the natural way, and in both the cæcal fistula was subsequently closed. The author advocates temporary typhlotomy in all cases where the obstruction proves to be above the descending colon, and, moreover, advises that the opening in the cæcum in the first instance be quite small, so that it may be easily closed should the obstruction subsequently give way and the stools pass through the normal channel.—*Annals of Surgery*.

Observations on Trional and Tetronal.—Drs. Rarmindi and Marioffini have been making some investigations upon trional and tetronal as hypnotics. Trional is chemically diethylsulphomethylethylmethane. It is a crystalline powder, fusing at 76° C., is soluble in cold water, but is more soluble in hot water and alcohol; it has a slightly bitter taste. Tetronal is diethylsulphodimethylmethane; it crystallizes in white flakes and is fusible at 86° C. It is soluble in water at the ordinary temperature, but it is more soluble in hot water and alcohol; it has a very bitter taste and an odor somewhat like camphor. As regards the clinical action of these bodies the investigators came to the following conclusions (*The Lancet*): 1. Trional and tetronal are hypnotics with an action similar to that of sulphonal; they act on the cortex of the brain. 2. One half or two thirds of a dose of trional or tetronal, respectively, produces the same hypnotic effect as a full dose of sulphonal. Both of the drugs were found to be successful after sulphonal had failed, but trional acted better than tetronal. 3. The general action of the ethyl group in producing hypnosis could be easily recognized, but at the same time an increase was noticed in the toxic action of these bodies in the following order: firstly, sulphonal; secondly, trional; thirdly, tetronal—in the proportions of 1, 1, and 3, respectively. 4. In small doses, neither trional nor tetronal produced any diaphoresis, nor did they have any effect on the temperature of the patient; sleep and respiration appeared to be normal. 5. As with morphia, a certain tolerance of the drug was soon established, and it was found to be necessary to gradually increase the dose of the drug in order to maintain its hypnotic effects. 6. There was a slight accumulative action, and toxic phenomena occasionally occurred. 7. The secondary symptoms of intoxication were the same as those of sulphonal—namely, prolonged somnolence, headache, a sensation of tension in the head, and in the early stages of inco-ordination of movement and ataxic debility. These phenomena were especially noticed after the prolonged use of tetronal in rather large doses. They ceased soon after the drug had been discontinued. 8. The ordinary therapeutic dose is from ten to thirty grains. When the use of the hypnotic requires to be prolonged—as, for instance, in the case of the insane—it is better not to employ tetronal, but trional or sulphonal. 9. The quantity of trional for a single dose varies from ten to forty-five grains, according to the age, sex, etc., of the patient. If a prompt effect is desired, it is advisable to administer the dose suspended in mucilage or milk, and to have the mixture warmed. Both trional and tetronal should be given at bedtime, and not some hours before, as is necessary with sulphonal.

Olive Oil for Lead Colic.—The *Gazette Médicale de Paris*, September 23, 1893, contains Combemale's report of cases of lead-poisoning treated medically by large doses of olive oil. For attacks of colic, oil was given by the tumblerful with most gratifying results. Sixty grammes of olive oil a day were administered in chronic lead-poisoning, with a resulting diminution in the tremor, in the difficulty of standing and walking, and all the nervous symptoms. The observer states that it is impossible to say just how olive-oil acts upon lead. The fact remains that doses of two hundred grammes will cure lead colic, and daily doses of sixty grammes will relieve many of the most distressing manifestations of plumbism.

The Joints in Osteo-arthritis.—The changes in the joints in osteo arthritis are described in the "American Text-book of Surgery." The articular cartilages are first affected. There occurs a fibrillary degeneration of the intercellular substance, with abundant new-growth of cartilage cells, and soon a breaking down and a disappearance of both, leaving the surface eroded and velvety; or, less often, smoothed and thinned. By pressure of the adjoining bone marked central thinning is produced. Later there is complete disappearance of the cartilage and exposure of the bone. This in turn wastes away, with resulting changes in its shape. While the central part of the articular surface is gradually wearing away, the peripheral portion is increasing in thickness, and grows into lips hanging over the edge. This increase of substance partly or wholly ossifies. The synovial fringes enlarge, new ones form, and outgrowths are developed. The original cartilage cells of the membrane proliferate greatly. Adhesions of the adjacent sides of the fringes take place. The capsule and ligaments, at first only congested and œdematous, after a time usually undergo degeneration, adhesions and contractions forming later. Occasionally, instead of becoming harder, they soften and permit undue movement of the joint. The irritated periosteum over the end of the affected bone throws out new bone, the osteophites at times being numerous and of considerable length. The interior of the joint is generally dry; it may, however, contain fluid in large quantity. Muscular atrophy occurs early. The tendons passing over the joint may harden and contract, may ossify, or become detached from the bone, or soften and disappear. As results of these various processes, deformity and restriction of movement follow in due time, though it

may take years for the arthritic changes to develop to this degree. Suppuration does not take place either in or about the joint, except in rare instances. In osteo-arthritis is found the one great exception to the rule of securing rest to a diseased joint. Immobilization is not indicated. Except in an acute attack, when pain is constantly present, active and passive movements of the joints must be kept as long and freely as possible. An inactive life, with its absence of fresh air and exercise, is the worst possible condition for anyone suffering from osteo arthritis. Want of exercise intensifies all the symptoms. Much sunlight is needed to keep the patient in relative health, and the best climate is one that is dry, equable, and warm.

Gout and Calomel.—In the *Journal de Médecine de Paris*, June 11, 1893, an account is given of F. Grimm's method of treating acute attacks of gout, and irregular and subacute gouty conditions with calomel in broken doses, until slight colic indicates the imminent purgative influence of the drug. When this slight colic begins, there is a sudden quieting of all the gouty symptoms. Pain is lessened, swelling, tenderness, and redness rapidly diminish, and in two or three days the patient is able to walk about. Sometimes good results are not so rapid. The same improvement follows, however, even if more slowly. Especially when constipation is a feature of the gouty condition is calomel valuable in breaking up the attack.

The Influence of Chloroform upon the Course of Normal Labor, as Shown by the Tachadynamometer.—Dr. Donhoff administered chloroform in various degrees to five cases of normal labor, and noticed its influence upon the expulsive force of the uterus and abdominal muscles, as shown by a carefully constructed physiological apparatus. The conclusions reached are in substance the following: 1. The administration of chloroform, even in diminutive doses, exercises a retarding influence upon the progress of labor. The muscular pressure sinks to one-half of the amount of that present before the administration of the anæsthetic. In eight observations the average figures were 1,837. 2. The expulsive force of the uterine contractions steadily diminishes during the exhibition of chloroform. 3. The labor pains, besides being weaker, are also more irregular during a slight anæsthesia. During deep anæsthesia the intervals between the pains are longer and all the pains are diminished in strength. 4. The pains increase immediately after discontinuing the anæsthetic. 5. The labor pains generally continue diminished in power for some time after discontinuing the chloroform. In one case they had resumed their normal intensity in ten minutes, while in two other cases two hours had expired. 6. If the action of the abdominal muscles is only slight, this action is checked entirely by a superficial anæsthesia, but soon reappears after the stopping of the chloroform. 7. The action of the abdominal muscles continues, but in diminished force, during superficial anæsthesia, if before the exhibition of the chloroform it was vigorous in character. 8. Deep anæsthesia abolishes entirely the action of the voluntary muscles. 9. The intervals between the pains become longer immediately after chloroform is administered, and the labor pains, besides being less intense, decrease in numbers about twenty-five per cent. These carefully conducted experiments show that chloroform, no matter in what degree it is administered, exercises a retarding influence upon the progress of labor. The expulsive forces are lessened, and there is no corresponding diminution of the resistance—*Medical Review.*

Treatment of Syphilis by Simple Application of Mercurial Ointment.—Dr. Welander finds simple application of gray salve to be as efficacious in the treatment of syphilis as inunction. In thirty cases where it was tried the various symptoms disappeared fully as quickly as with a carefully carried out treatment by inunction. Among these were four pregnant women with pronounced symptoms of secondary syphilis, and all these went on to labor at full term—a good proof of the efficacy of this method. Examination of the urine demonstrated that mercury was excreted by the kidneys. The procedure is very simple. Each evening on going to bed one and a half drachm of the ointment are spread on a portion of the body by means of a knife or spatula, and covered with a piece of linen. The patient keeps himself warmly covered in bed, yet not too warm, for profuse perspiration would rather hinder than favor absorption. The next morning the salve is washed off and a warm bath of ten to fifteen minutes' duration is taken. In this way the treatment is continued every evening, another portion of the body being chosen, as in inunctions. Of course requisite care of the mouth must be observed. This method is much simpler than inunctions, and does not irritate the skin. He thinks that the salve containing more mercury could be employed, as, for example, Ziemssen's, which consists of two parts of mercury and one of pure fat.—*The Cincinnati Lancet-Clinic.*

Opium and Bromide for Epilepsy.—Opium associated with bromide is advocated by Flechsig in the *Neurologisches Centralblat*, No. 7, 1893, as superior to bromide alone. Pills of powdered opium are given two or three times a day, the strength of the dose being gradually increased during a period of six weeks, when the drug is abruptly dropped and replaced by large doses of bromide of potassium. The large doses of potassium are continued for two months. Then they are gradually reduced to a daily portion of two grammes. The opium has a preparatory effect, facilitating and strengthening the action of the bromide. During the opium period of treatment the only amelioration is a temporary suspension of the attacks, or a decrease in their frequency. Two cases are recorded of complete cure by this method, when all other known remedies had failed.

Affections of the Testicle in Hereditary Syphilis.—Dr. Carpenter passes in review much that has been written upon this interesting subject, and relates many interesting cases, which will aid future investigators in the solution of the difficulties surrounding it. In summing up the present state of knowledge it would appear that, 1. The testicles may be affected so slightly in congenital syphilis that it needs the microscope to detect the malady. 2. In a certain small percentage of cases of congenital syphilis the lesions of the testicle are such that they can be detected by physical examination. These lesions may be present at birth, arise soon after, or make their appearance some months or years afterward. The general rule, however, seems to be from birth up to two or three years, not often much after this time, and very rarely indeed at puberty. Fournier's case of twenty-four years seems to be the present extreme limit. Syphilitic orchitis may, as has been before remarked, arise when the patient is apparently thoroughly under the influence of mercury, but in this latter respect it does not differ from other syphilitic manifestations. 3. The globe is, more often than not, alone affected, but, not infrequently the globe and epididymis suffer together, and quite exceptionally the epididymis is attacked singly. It appears from Bumstead and Taylor, that the cord may suffer, and in one of Obédénaro's cases it was as thick as a child's thumb. The vas, vesiculæ seminales, and prostate are not attacked: at least so far there has been no record of such a complication. 4. The disease is very frequently, but not invariably, bilateral in its distribution, though one side may be more advanced in pathological changes than the other. 5. Hydrocele of the tunica vaginalis is not such an infrequent accompaniment of the malady as some writers would have us believe, and it may be, in young infants, the earliest indication that there is something wrong with the testicles. In all probability, as time goes on, the fluid is reabsorbed, and then the condition of the gland itself becomes more marked. 6. There is just a possibility that hydrocele of the cord may, in some instances, owe its origin to congenital syphilis. 7. The

swelling of the testicle is a painless one, it feels like scirrhus; it may, or may not, be nodular, the latter for the most part, and a fungus testis is sometimes seen. 8. The enlargement of the affected organ is usually not great, and in fact there may be none at all, it being a very rare occurrence indeed to find in infants and children a testicle the size of an egg. 9. In the large majority of instances the microscopical appearance is that of the simple inflammatory form, passing on to the development of fibrous tissue with consequent destruction of the gland, leading possibly, if not attacked in time by suitable remedies, to impotence and sterility. Certain atrophied organs may be accounted for in this manner. A scrotum, of natural or almost natural dimensions, containing an atrophied organ, the vas, seminal vesicles, and prostate being free, with marks of congenital syphilis on the person, in the shape of scars on the buttocks, fissures round the mouth, characteristic teeth and physiognomy, specific eye troubles, or what not, would suggest such a causation. The inflammatory form is akin to that observed in the liver. Gummata, on the other hand, are rare manifestations.—*Journal of Cutaneous and Genito-urinary Diseases.*

Renal Tuberculosis.—Dr. Tuffier points out that in addition to hydronephrosis of tuberculous origin, there is also a variety of renal tuberculosis characterized by paroxysmal pain indistinguishable from that of nephritic colic, without detectable enlargement of the kidney and without pyuria or hæmaturia, although it may be possible to find tubercle bacilli in the urine. Besides this form of renal tuberculosis there is another, characterized by the occurrence of hæmaturia, and corresponding to the form of pulmonary tuberculosis attended with hæmoptysis. A case is reported in a woman, forty-two years of age, of good family and personal history, who in September, 1888, after a long walk, not especially attended with fatigue, was suddenly seized with hæmaturia. There was no pain, but a sense of burning referred to the bladder. The urine soon resumed its normal appearance. Thereafter, the hæmaturia was repeated from time to time, after intervals of varying duration in which the urine appeared quite normal. The woman became extremely anæmic, almost cachectic in appearance, and weakness became marked. The urine examined in an interval between two attacks presented no abnormality. The physical examination was facilitated by the marked emaciation, but it was not possible to detect any enlargement or lesion of kidney, ureter, or bladder. The manipulation was unattended with pain. The patient at this time would not submit to a cystoscopic examination. Examination of heart, lungs, and other viscera failed to disclose the existence of organic disease. Upon the strength of the evidence it was concluded that there must be a neoplasm of the kidney or of the bladder, the character of the hæmaturia pointing to the bladder. Accordingly the bladder was opened through a hypogastric incision and explored, but no lesion was found. The wound of operation closed readily and without untoward event; but after the lapse of two months there developed in the course of the cicatrix a small spot of fungous ulceration, of the tuberculous nature of which there was no doubt. Shortly afterward hæmaturia recurred, and now a diagnosis of renal tuberculosis was ventured. The right kidney appeared to be a little the larger, but the left was slightly painful. Cystoscopic examination yielded a negative result; for the patient was greatly agitated and, perhaps as a result of spasm, not a drop of blood escaped from either ureter during a period of ten minutes. A second examination, however, showed clearly that the blood came through the left ureter, while the secretion of the right kidney appeared to be normal. In view of the gravity of the situation it was determined to operate at once, and incise and scrape the kidney or excise it, according to the conditions found. No change was found in the tissues surrounding the kidney. The organ itself was not enlarged, but within its parenchyma several fluctuating areas of softening were found. No enlargement of adjacent lymphatic glands was detected. The organ was removed. There was no surgical complication, and five weeks after the operation the patient appeared to be perfectly well. Tubercle bacilli were found in the contents of the abscesses. There was, however, no communication with pelvis or ureter.—*The American Journal of the Medical Sciences.*

The Knee-jerk.—Dr. Sherrington has contributed to the proceedings of the Royal Society a paper in reference to this much-discussed phenomenon. The same observer recently pointed out that the muscular part of the mechanism consists of the vastus internus and part of the crureus division of the quadriceps extensor of the thigh. In the Rhesus monkey the spinal centre was found to lie in the fifth and fourth lumbar segments of the cord, corresponding to the fourth and third in man (*The Lancet*). The efferent path was found to lie in the fifth and fourth lumbar nerves, and was traceable in the anterior crural nerve to the muscles in question, while the afferent path was found to lie in the posterior root of the fifth lumbar, and possibly to a small extent also in the fourth lumbar root. This fifth posterior root runs in fibres from the obturator nerve, the anterior crural, the external and internal popliteal nerves, and also from the branch of the sciatic nerve distributed to the hamstring muscles, conveniently named the "hamstring nerve;" but of all these fibres only those from the anterior crural nerve from the afferent path on which the jerk depends, and in the anterior crural nerve only those fibres which issue from the vastus internus and the crureus muscles. Various methods were resorted to in order to test the conductivity of this root, *e.g.*, severance, partial or complete, and cooling by the indirect application of ice and salt, by carbonic acid vapor and the application of cocaine; and by lowering the conductivity of the posterior root by such means, it was found that the knee-jerk could be abolished, even if conductivity was not impaired, to such an extent as to make the transmission of skin impulses impossible. Thus, merely lifting the posterior root by a thread will often suffice to prevent the jerk from being obtained, while the afferents of tactile sense are not obviously impaired in their function. Dr. Sherrington also found that excitation of the central end of the divided hamstring nerve at once abolished or greatly reduced the briskness of the jerk. In the paper already alluded to he had pointed out that the jerk could be rendered brisk by section of afferent or efferent spinal roots, immediately below those on which the jerk itself depended. The explanation then offered was that it depended on the fact that the tone of the hamstring muscles was abolished by section of the afferent roots belonging to them. By a series of ingenious experiments this explanation is confirmed and expanded. The fact was pointed out by Tschiriew that severance of the great sciatic nerve produces increased briskness of the jerk, and this Dr. Sherrington finds to depend upon the section of that part of the sciatic nerve which he has called the hamstring nerve; from the experiments already alluded to he thinks it clear that this exaggeration is not the result simply of muscular relaxation, leaving the joint mechanically free to move, but of an interruption of a stream of centripetal impulses passing up from the hamstring muscles and exerting a depressing or restraining influence upon the jerk. He also finds that a stream of impulses, similarly efficient, can be set up by stimulation of the central ends of the divided nerves of the hamstring muscles, or by simply stretching or kneading the muscles when they are released from one of their fixed points, or, finally, by throwing the muscles into contraction by excitation of motor roots supplying them, so long as the sensory roots remain intact.

Chorea Cured by Cerebrin.—A case of chorea associated with rheumatism is reported by Montagnon, in the *Lyon Médical*, September 17, 1893, as cured within thirty days by injections of cerebrin. A twenty per cent. solution was used at first, and then a ten per cent. solution.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, November 4, 1893.

PUBLIC HEALTH BILL OF THE ACADEMY OF MEDICINE.

THE Quarantine Committee of the Academy of Medicine has completed its draft of a Public Health Bill, and in our columns of this week we give the full text. It is the outcome of an exhaustive examination of all of the health bills heretofore introduced into Congress, of the laws at present in existence, and of the health laws of other countries. We may add that, as the Committee extensively circulated tentative drafts of the bill and invited criticisms and suggestions from the ablest sanitarians in this country, large numbers of whom responded, the bill embodies the best thought and experience of the practical laborers in the field of preventive medicine.

In referring to the more important features of the bill, we may premise that it is quite impossible for any committee to draft a measure, susceptible of so many modifications in details, which will meet universal assent. It was in this view that the Committee very wisely determined to submit a first draft to public criticism and thus obtain every diverse opinion possible, in the hope that in the final draft it could harmonize conflicting ideas, and concentrate on one measure the united support of every person and organization interested in the proposed legislation.

The provisions of the bill which are most susceptible of criticism we shall briefly notice.

1. The bill creates a Bureau of Public Health in the Treasury Department, instead of an independent Department of Public Health. To those familiar with the history of the public service of the General Government there is a manifest necessity of organizing a new branch within a department most likely to aid it in the performance of its special duties. It is quite impossible to create a new and full-fledged Department. There must first be a demonstration of the value and necessity of the special service undertaken before any consideration will be given by Congress to a proposition to make a new Department The Treasury Department has, from the origin of our government, been intimately associated with quarantine and the health of sailors through its Custom House officers and the Marine Hospital Service. It is thereby especially adapted to foster that branch of a public-health service devoted to the regulation and supervision of a maritime quarantine. The relation of the Treasury Department to interstate commerce equally adapts it to aid in the development and practical enforcement of a permanent system of sanitary regulations which will prevent the spread of contagious and infectious diseases from one State to another.

2. The Bureau is placed under the control of a commission instead of a single officer. The importance of this feature of the bill will appear if we consider the nature of the duties that devolve upon the Bureau. These duties are legislative, executive, and judicial. It must make the rules and regulations which shall hereafter govern maritime and interstate travel and commerce; and those rules and regulations, when approved by the Secretary of the Treasury, will have the force of law. It must execute largely its own rules and regulations at foreign seaports, on the sea, and at our own seaports and throughout the United States. Finally, it must interpret its own acts judicially, and sit in judgment upon the acts of other health officers. These are duties which cannot safely be intrusted to a single individual, however great his abilities or enlarged his experience.

3. In providing a suitable commission, the Committee has happily conformed to the genius of our Government, and made it a representative body. The members represent, not States, but sanitary districts, which have been very judiciously grouped so that the public health interests of every section are properly represented. The Committee seem to us to have devised far the best method of creating a central health authority yet proposed. Representation by States, sometimes suggested, would have involved a large and unwieldy body. And even this end is attained, as far as it may be desirable, by the power given to invite the State Boards of Health to send representatives to meet the commission in conference as often as the interests of the service may require.

4. The provision for an executive committee, which by the location of its members will practically be in continuous session, is an important feature of the bill. As in the case of the head of the Bureau, a commission is far preferable to a single officer, so an executive committee is preferable to a single executive officer, when the members of that committee are experienced men and can meet at a few moments' notice. Most of the questions which the executive committee are called upon to decide should not be left to the judgment of one person, but require for their proper determination the careful consideration of a council of experts.

5. The composition of the commission is eminently judicious. The representatives from the sanitary districts are to be medical sanitarians, and as they are to be nine in number they form the majority of the commission, and hence are the foundation on which it rests. The terms of service of these members are so classified that one-third retire annually, thus giving continuity to the service. The two members appointed at large are not necessarily medical men, and their terms of service are lengthened to six years, but one retires every three years. As one of these members must be the president of the commission, the arrangement seems well adapted to preserve the organization and work of the commission from any sudden or radical changes.

We need not discuss the details of the bill. Its more important provisions are already the law under which the Treasury Department performs its health functions. The new sections are chiefly derived from bills which have already been before Congress, and are essential to the perfection of the measure.

Whatever may be the final result of the labors of the Committee, the Academy of Medicine is certainly entitled to the highest commendation for its effort to secure an adequate public health administration in the General Government. How far the Academy will succeed in this undertaking time alone will determine, but it is to be hoped that not only all factious opposition will be withheld, but that the Committee, which is acting with full power, will receive the prompt and cordial support of medical societies, State and municipal health authorities and boards of trade, in its further efforts to obtain the enactment of this measure by Congress.

MORE MILLIONS FOR OUR HOSPITALS.

To them that have it shall be given. Neither the New York Hospital nor the Presbyterian are in distressing need of money, yet by the will of the late Charles B. Beck, each will receive about $900,000. New York's reputation for being the city of magnificent and many-millioned hospitals, is not likely to decline. Yet how much more really urgent is the need in this community of money for our medical educational institutions. Our undergraduate colleges are still behind Philadelphia, Boston, and Baltimore in the standard set for medical students, though this will, we trust, not long be the case. The two hospitals which have just been so handsomely remembered do not contribute much to our educational work, not being attached to any colleges.

HOMICIDAL CRANKS.

The recent shocking murder of Mayor Harrison calls attention again to the danger to which society is subjected by the half-mad. We cannot pretend to give a complete list of the assassinations and attempted assassinations of public men in this country and Europe during the past ten or twelve years. But our readers will recall the murder of Garfield, by Guiteau, the attempted murder of Frick, by a Jewish anarchist, the dynamiting of Russell Sage by Norcross, and the attempted shooting of the Rev. Dr. Hall. All these crimes were done by men of a somewhat similar character, and all suffered from a somewhat similar form of mental and moral perversion. The name which science gives to their malady is paranoia persecutoria. It is not, however, so much a real disease as it is an inherent defect in the structure of the brain.

This defect exists in many, but it is overcome and controlled by education and training. In the homicidal paranoiac natural defects and natural bad propensities are increased by bad habits of life and thought. For example, by the over-indulgence in alcohol, tobacco, and excitable haranguing, a man who has simply exaggerated political views becomes a political criminal or a murderer.

The question naturally arises whether the homicidal paranoiac has come with us to stay and to increase in numbers and activity. Already it is necessary for public men to exercise care in admitting people to audience, and the life of the American millionaire, or high political functionary, is perhaps already quite as uneasy as that of the Czar of Russia.

We see no immediate prospect of relief from this condition of things. Certainly lynching will do no good, though so strongly recommended by many. Whether such people should be hanged is a question to be decided in each individual case. In some instances it is surely necessary and helpful, even if from our stand-point it seems cruel. But cranks and paranoiacs will not be suppressed by hanging, because they often love notoriety more than they fear death, or are impelled to their act by a morbid instinct which no prospect of future punishment can suppress.

The paranoiac is the result of bad breeding, and he will flourish as long as neurotic people intermarry and give birth to children whose morbid tendencies are allowed to develop. To prevent the increase of the paranoiacs we need good fathers and mothers.

ENGLISH AND AMERICAN DOCTORS.

The bright English journal called *The Hospital*, devoted to science, medicine, nursing, and philanthropy, publishes, in the issue of July 15, 1893, a view of English and American doctors. Its little preachment has for text the late meeting in congress of the editors and conductors of about four hundred American medical journals. The bare announcement that there are four hundred medical journals in America almost takes the breath away, so says *The Hospital*. How many are there in England? Four dozen? More than four or five that a physiologist would declare to be living and in normal health? The population of Great Britain is more than half the population of the whole of the United States. It is evident that different conditions obtain in America, where the most striking characteristics of modern medicine are courage and freedom. The American's boldness and the Englishman's caution both possess merit. But caution can be too cautious, and then it becomes a limitation. Better crude experiments than to make no experiments at all. England assigns experimentation to a handful and freedom to a class. The bold man claims freedom, and it is granted because he had the courage to take it. The timid is forbidden to open his lips, except by permission. Independence of mind is the true and open secret of American progress. The day is dawning when a like independence will be universal in Great Britain. The men from Oxford, Cambridge, and other ancient universities, who are going all over the country, will submit to no dictation. Freedom of thought, of tongue, of pen, freedom the largest and most absolute, is the inheritance of every medical man as of every Englishman.

A little enthusiasm, a little fearlessness, would put life into the somewhat rusty and creaking machine of English general medicine. Too much dread of the English critic, the terrible man with the pen who writes reviews for the medical journals, prevails in England. But good work well done pays small attention to the irresponsible judgments of the unlearned in large and philosophical medicine. Modern medicine is not a thing of unmeaning traditions and senseless etiquette. It is a living science, a noble art. All its ethics worthy of the name come under the golden rule. And with this rule as a guiding star, medical men in England, like their brethren in America, may claim and use that bold, unshackled freedom which is the first essential of progress and true intellectual greatness.

LAVAGE OF THE WHOLE INTESTINAL TRACT.

It has no doubt often occurred to physicians that a washing out and scrubbing down of the entire intestinal tract would be a most desirable thing to accomplish. We have already succeeded in washing out the stomach satisfactorily, also the large intestine. But there are some twenty odd feet of small intestine which have heretofore defied laundry therapeutics.

In a recent issue of the *Progrès Médical*, Dr. Antoine de Genersch, a Hungarian physician, describes some experiences of his in antiseptic irrigation of the whole digestive tube. This has brought out Dr. Jules Dauriac (*Progrès Médical*, September 30th), who gives his experiments together with some definite conclusions regarding the same subject. Working in the service of Dr. Bourneville, the writer states that he gave total intestinal lavage to eleven infants, who were suffering from obstinate fetid diarrhœas. In all instances the disease was checked. The fluid used was a weak solution of lactic acid, which was forced in through the rectum until evidence of its reaching the stomach was obtained. In five other cases a weak solution of creoline was employed. One case of typhoid fever was treated in the same way with good results. Every day about five litres of the solution was introduced, at a pressure not exceeding sixty centimetres. The treatment was also employed in catarrhal jaundice.

Dr. Dauriac thinks it proved that a partial or complete lavage of the whole intestinal tract can be given safely. He believes that the procedure will have a great utility in the future, when the technique has been perfected.

THE ABANDONMENT OF LITHOTOMY.

Hyderabad is a country which to most of us appears very far away from the great centres of scientific progress, yet it shows itself to be an extremely active surgical focus. The Hyderabad Commission aroused the whole surgical and physiological world to a renewed discussion of anæsthesia. And now Dr. J. Forbes Keith, of the same place, comes forward advocating the entire abandonment of the cutting operation for stone. (The *Lancet*, September 30, 1893.) The advantages of this abandonment ought to be stated first, and they are shown in a statistical table compiled by Dr. Keith. During four years of lithotomy by this surgeon the mortality among 367 cases was 7.8 per cent., while in five years the mortality from lithotrity was, among 1,158 cases, 2.5 and 1.9 per cent. The mortality among 408 cases during the year 1893, when all cases were treated by lithotrity, was only 0.5 per cent. This is surely a brilliant showing, and if Hyderabad surgical conditions are similar to those of other countries, the new methods of Dr. Keith ought to be adopted.

Dr. Keith adapts lithotrity to all kinds and sizes of stones, by two means: first he cuts open the membranous urethra, introduces through its prostatic portion an extra-large lithotrite, and then crushes the stone by striking the male screw with a hammer; next, in very hard stones he introduces first a lithotome by which he cuts the stones into pieces. The description of his plan of work deserves insertion here. He says:

"We have now, in male and female alike, advanced lithotrity to limits circumscribed by the largest instruments available. The largest lithotrite in Bigelow's case locks on stones a little over one inch and a half in diameter; but many cases of stone are admitted into hospital with diameters which are much larger than this instrument can embrace. Seeing the ease with which the largest lithotrites traversed the urethra of the female and the prostatic portion of the male after slitting up of the membranous part, and being thoroughly convinced in my own mind that lithotrites of much larger size could be readily introduced into the bladder of both sexes, and that thus much larger stones could be brought within the sphere of lithotrity, causing a corresponding abandonment of the cutting operations for removing calculi entire from the bladder, I sent a description of the new kind of instrument I wanted to Messrs. Coxeter & Son, and afterward found that this new lithotrite answered my purpose in every way. It was a bold, massive, compact, and highly-finished instrument, the peculiarities of which were its length of male screw (embracing calculi of two inches and a half in diameter) and its long and massive jaws. I had not long to wait before its merits were put to the test, and to my great satisfaction I found that it was as sensitive and easily handled as any of my smaller lithotrites. For breaking up calculi in the first instance this lithotrite is a complete success; and I find that by its use I can remove large calculi with almost as much safety to the patient as I can do smaller stones, with this difference, that the patient is much longer under the influence of chloroform. The small wound in the perineum is of little consequence, as will be seen in the sequel."

The description of the lithotome and its method of use is too detailed for insertion here. Dr. Keith says, however, that he has used it now successfully in five cases.

News of the Week.

Sir Andrew Clark, of London, Seriously Ill.—On October 19th he saw a number of patients in the morning and seemed in his usual health, but soon after noon his butler found him in a state of unconsciousness on the floor of his room. The help of his medical neighbors was at once procured, and it was evident he had been suddenly seized with paraplegia. He partially recovered consciousness the next day and appeared to recognize those in attendance, but had lost the power of speech and the use of the left arm. On Saturday, when the mail left, he was reported to be a little better, but his medical attendants and family were in a state of anxiety, and his numerous friends looked with apprehension to the consequences.—*Our London Correspondent.*

Tobacco for the Insane.—The State Commission in Lunacy of New York having denied the requisition for tobacco for the patients of the Hudson River State Hospital at Poughkeepsie, on the flimsy pretence that there was danger of fire by pipe-smoking, the Board of Managers, through its Committee, has made the following protest:

"To the State Commission in Lunacy. The managers of the Hudson River State Hospital for the Insane, in session at a regular meeting held at Poughkeepsie on October 28, 1893, desire to respectfully protest against the passage or enforcement of any rules or regulations of your Commission prohibiting the use of tobacco by the patients in said hospital. In many in-

stances it is the principal solace and comfort appreciable by them in their unfortunate condition, and to be deprived of its use after being habituated thereto for long periods, often nearly an ordinary life-time, would result in genuine distress and hardship. It is also believed that in many cases deprivation from the use of tobacco would be attended with both mental and physical injury to the patients. In the interest, therefore, of humanity as well as from a medical standpoint, the managers urge that no action be taken by your body looking to the passage or enforcement of the rule or regulation in question."

The Yellow Fever continues at Brunswick, Ga., there still being about twelve new cases daily. The epidemic is declining, however, and all fear of its extension has disappeared. The local quarantine has been raised.

A Tooth-making Boy.—Dr. O. Hildebrand, of Göttingen, reports the case of a boy of fourteen, who since the age of twelve years had had from a hundred and fifty to two hundred teeth of various sizes removed. A year and a half later seventeen more were removed, with evidences of others coming. The boy's jaws seemed to be a perennial fountain of teeth.

Cures for Inebriety.—It is interesting to learn that the action for libel brought by Dr. Leslie E. Keeley, of "gold cure" notoriety, against the editors of *The Lancet*, has been discontinued by him, and that he will have to pay the taxed costs of the action.

The Philadelphia County Medical Society and Nostrums.—At a meeting of the Philadelphia County Medical Society, held October 18, 1893, the following resolution was unanimously adopted:

"Whereas, Dr. James E. Reeves, of Chattanooga, having denounced the so-called 'Amick Cure' for consumption as a quack nostrum, and stated that its proprietor was not a physician in good and regular standing, was accused of criminal libel; and

"Whereas, The grand jury has ignored the indictment brought against him; be it

"*Resolved*, That the Philadelphia County Medical Society congratulates Dr. Reeves on his bravery, a bravery unfortunately too rare at the present day, and tenders him sympathy in the persecution to which he has been subjected.

"*Resolved*, That no person who makes, deals in, or advertises as a cure a quack nostrum, that is to say, a preparation the composition of which is kept secret, can be termed a physician in good and regular standing, because such action is *ipso facto* sufficient to cause forfeiture of membership in this or any other County Medical Society governed by the laws of the American Medical Association.

"*Resolved*, That a copy of these resolutions, duly attested with the signature of the President and Secretary, and with the seal of the Society, be forwarded to Dr. Reeves, and that they be handed to the press for publication."

As a fitting supplement, it may be stated that Dr. Reeves has won his case in court.

New Medical College.—The trustees of the Kansas Medical College met at Topeka, October 9th, and voted to erect a new college building. Francis Storrs, M.D., was elected Instructor in Latin, and G. L. Beers, A.M., M.D., Professor of Materia Medica and Therapeutics.

New Hospital at San Francisco.—The new hospital annex of the Cooper Medical College of San Francisco, will be opened some time next summer. The building will cost somewhere in the neighborhood of $150,000, and will have a capacity of one hundred beds.

Dr. George W. Jarman has been elected attending gynecologist to the New York Cancer Hospital

A Tribute to the Late Dr. Peters.—A correspondent of the *Evening Post* writes: "Sir: I notice the death of Dr. John C. Peters, and would like to put on record, in your columns, a little testimony as to his patriotism. In 1862 I was a lieutenant in a New York regiment, and participated in the Chickahominy campaign against Richmond. When the army had effected its change of base and reached the James River, I was among the number stricken with 'Chickahominy fever,' and was sent to my home in this city for treatment. Dr. John C. Peters was called in, and most faithfully did he care for me, calling two and three times a day while the fever was at its worst. When finally I was ready for duty, I called for his bill, whereupon he said: 'I am, like many others in my profession, debarred from going to the front, where my sympathies lie, for I have responsibilities at home that prevent. But my heart is wholly with our soldiers, and as I cannot share their perils, the next best thing I can do is to take care of them professionally when they fall into my hands. I make no charge for services rendered our sick soldiers, and I have no bill against you.' There are other old soldiers who can bear witness to similar kindnesses received at his hands, and now that he has gone to his reward I am sure they will be remembered to his credit."

The Empress of Russia's Physician when in attendance upon his imperial patient receives a fee of $350 a day (700 rubles).

Legacy to Philadelphia Hospitals.—The Ingersoll estate was partially divided, October 11th, by which the Episcopal Hospital, the Children's Hospital, and the Consumptives' Home, all of Philadelphia, each received one third of $476,574.67, the residue on hand at the date of the distribution.

A Centenarian.—A man, named Pedro Erello, is said to have died on July 12th, at Tarimors, in Mexico, at the patriarchal age of one hundred and thirty-three, leaving four hundred living descendants. The funeral, which was largely attended by his family, was, for obvious reasons, held in a church.

Antiseptic Hairdressing.—The Government of the Republic of Colombia has, in view of the possibility of contagious diseases such as ringworm, favus, and syphilis, being transmitted by combs, brushes, etc., passed an enactment making it compulsory for all barbers and hairdressers to keep the instruments of their art clean, and to disinfect them every time they have been used. A notice to this effect is to be posted up in all tonsorial establishments.

Hypnotism in Russia.—The practice of hypnotism, which has hitherto been forbidden in Russia, has recently been legalized, subject to the restrictions indicated by the Minister of the Interior as follows: "Physicians

must strictly observe the provisions of Art. 115 of the Medical Code; they must inform the administrative authorities of their intervention in each case, mentioning the name of the physician present at the sitting. All advertisement of treatment is forbidden."

St. Luke's Hospital.—Dr. Van Horne Norris has been made an Attending Physician.

Hospital Graduates' Club.—The following officers are elected for the ensuing year: *President*, Dr. N. H. Henry; *Vice-President*, Dr. T. T. Janeway; *Secretary*, Dr. F. A. Manning; *Executive Committee*, Drs. W. R. Townsend and C. A. Powers.

Death of Dr. A. W. Heise, of Joliet, Ill.—Adolphus W. Heise, M.D., aged seventy years, died of sclerosis of the brain in Joliet, Ill., October 22, 1893. Born in Bramsche, Germany, he was graduated from Heidelberg in 1842, and from Goettingen in 1846. Taking part in the revolution in 1848 he was compelled to leave the country and come to America. In 1849 he located in Du Page Co., Ill., and practised there until 1856, when he went to New York, was house surgeon in the Marine Hospital on Ward's Island in 1857, and then came to Joliet. Was surgeon of the Eleventh Regiment, Illinois Volunteer Infantry, three months service, and then of the One-hundreth Regiment. After the battle of Murphreesboro was promoted to Brigade Surgeon and Operator of the Brigade, which position he held until compelled to resign in 1864 on account of ill health.

Alfred Ludlow Carroll, M.D., died October 30th at his residence, 30 West Fifty-ninth street, after a short illness. Dr. Carroll was born here on August 4, 1833. He was a son of the late Anthony Carroll. In 1855 he was graduated from the medical department of the University. He was a student under and assistant to Dr. Valentine Mott. Dr. Carroll practised medicine in this city until 1871, when he removed to Staten Island. He organized the Board of Health on Staten Island, and was its first President. While living at Staten Island he was appointed Secretary of the State Board of Health. In 1889 he resumed his practice in New York City. Dr. Carroll was one of the originators of the New York State Medical Association, and was also a member of the British Medical Association. He was instrumental in organizing the Society of Letters, Arts, and Sciences. He is survived by two sons.

To the profession the deceased was well known as an indefatigable worker, a citizen of exceptionable public spirit, a graceful writer, and fluent debater. In disposition amiable, he won many friends, who yielded homage to his great abilities while they regretted the extreme modesty which tended to obscure them. All in all, he was a most admirable gentleman, and much that he offered will abide with us. His remains were interred in the family vault in old St. Mark's Churchyard.

New York State Association of Railway Surgeons.—The third Annual Meeting is to be held in the Academy of Medicine, 17 West Forty-third Street, New York City, Wednesday, November 15, 1893.

Russian Physicians.—There are 12,000 male physicians in Russia, of whom 2,500 are in the army, and 400 female physicians. There is one doctor to every 12,000 people.

Reviews and Notices of Books.

A Manual for Boards of Health and Health Officers. By Lewis Balch, M.D., Ph.D., Secretary of the Board of Health, State of New York. Albany and New York: Banks & Brothers.

The Legislature of this State passed the Health Law some years ago, organizing a State Board which should be a central body having authority, and creating local boards in towns, counties, and villages, which should all ultimately form a part of one system. "Ultimately," because the local health officers were to learn as the months went by the duties of their office, and the local boards were to be taught how and when they should act in the interests of the public health, either in their own municipalities or away from them. The work of teaching them was under the law placed on the Secretary of the State Board, because he, as the Executive officer, found himself obliged to answer the ceaseless inquiries from the local boards as to the meaning of the law itself, or of the various resolutions passed by the State Board. The efficiency of the boards of health of the State of New York, their power of united action, and the sureness with which they will handle any disease dangerous to the public health, is the result of the never-ending work of the Secretaries of the State Board.

Dr. Lewis Balch, the present secretary, has been longer in his office than any of his predecessors. During his time the work of the State Board has grown in most amazing fashion, and the local boards have become more efficient than ever. The reason of this growth, the letters which he has had to answer, is the origin of this book which he has just published. No one could have written this Manual who had not before him the innumerable questions which many men of many minds have asked. In no other way could the difficulties which the law presents to those unfamiliar with it, have been known, and it is but justice to Dr. Balch to say that he solves these difficulties to the full.

The book is the most practical of Manuals on the Public Health Law of New York. It explains the relations between the State and local boards, the duties of each, the powers of the latter in their municipalities, the procedure necessary to make their work legal, the measures which should be taken to preserve the health of the people, as well as those which should follow the outbreak of contagious disease. Each subject is treated fully and clearly. Blank forms of Vital Statistic returns are filled up, and the Health Law is bound up with the Manual, which explains it. It is one of the most practical works that we have seen, and will be of value to all interested in the public health.

Transactions of American Pediatric Society. Fourth Session, Held at Boston. Edited by William Perry Watson, A.M., M.D. Vol. IV. Bailey & Fairchild. 8vo, pp. 276. 1893.

This volume contains several interesting papers on Diphtheria, Typhoid Fever, and Chorea, with a scholarly address on Specialism, by the retiring President, Professor William Osler, of Philadelphia.

Lessons in Physical Diagnosis. By Alfred L. Loomis, M.D., LL.D., Professor of Practice of Medicine and Pathology, University of the City of New York. Tenth Edition. 8vo, pp. 278. New York: William Wood & Co. 1893.

This work long ago won for itself a leading position in its line. In the present edition the section on the physiological action of the heart, and the lesson on examination of the urine, have been entirely rewritten, while a new lesson on clinical microscopy has been added. At present it may be considered to be as complete a guide within its compass as can be obtained in any language.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 5, 1893.

D. B. St. John Roosa, M.D., President, in the Chair.

Report of the Statistical Secretary.—Dr. A. B. Judson, Statistical Secretary, reported the deaths of members since the meeting in June. The number had been unusually large.

Accessions to the Library.—Dr. Edward S. Peck, Executive Librarian, reported that since the last meeting the library had received 77 volumes, 533 pamphlets, and 8,359 numbers of medical journals.

Dr. M. Allen Starr, Corresponding Secretary, said he had received an official announcement of the death of Dr. Charcot, which the Council had duly acknowledged.

Memorial of Charles Carroll Lee, M.D.—Dr. H. T. Hanks read a touching memorial of the late Dr. Lee, former Vice-President of the Academy, and at the time of his death President of the County Medical Society. The address referred to Dr. Lee as possessing in the highest degree the qualities of respect for his fellow-man, earnestness of purpose, attention to duty, affability, dignity, and friendship. His success was due more to persistence than to flights of genius. He was very popular with the medical profession, was loved and respected by his patients, and his family life was a model in every respect.

A Club for Medical Men.—The President stated that the buffet would be open by the next meeting, when the members of the Academy could obtain refreshments and cultivate the social amenities. He hoped the club life of the Academy would prove as successful as had the scientific work.

Some Therapeutic Reflections.—Dr. Simon Baruch presented the paper in the spirit of the prudent merchant who found it desirable from time to time to take an account of stock. Lessons should be drawn from our own and our forefathers' experience. Many remedies much lauded at one time came to be cast aside either as harmful, valueless, or inferior to others. Among these was venesection. The opium treatment of peritonitis had given place to salines. The examples of change, presumably for the better, could be multiplied many times. How often could we conscientiously say that we had accomplished by a given medicinal agent the cure or removal of a disease? With the exception of quinine, perhaps mercury and the iodides, there was scarcely a single agent which could be considered as actually curative. Yet we constantly met with physicians who acted on the contrary view. The faith of some physicians in drugs rivalled that of the laity. The temperature could readily be reduced by drugs from 105° to 100° F., and, as in a certain case of pneumonia treated by veratrum viride, we might have the satisfaction of seeing our patient die with almost a normal temperature. There was too much strife for symptom remedies. As pathologists it was our work to discover disease in the organs, but as physicians we must act before. To guard against the development of altered or interrupted function into organic disease was the duty of the true physician. He must learn that medicinal agents played an unimportant rôle. We must consider the mode of living—the breathing, eating, exercise, recreation, etc. Attention to these facts would give a surer basis for effecting a cure and in preventing disease than all medicinal agents from ancient gentian to modern quinine. A correct early diagnosis was important for a favorable issue. Anodynes often left the physician with a sense of false security. Example: In cases of appendicitis our remedies were often a burden to the kidneys and skin, which should be channels of vicarious action. In acute conditions rest was indicated; in chronic conditions, rest judiciously alternated with activity of organs. The superiority of physiological or hygienic methods over medicinal, as a rule, was illustrated by the action of water upon typhoid patients. In spite of the improved statistics shown by the Brandt method, in only three hospitals of the city had it come to be the chief treatment of typhoid fever. Chlorosis was treated almost universally by iron, yet how much superior would be a change to mountainous regions with out-of-door exercise and wholesome food. If one-third the attention given by the profession to new drugs were given to the study and application of hydrotherapy the race would soon rise and call us blessed. The modern physician was enslaved by the drug-prescribing habit.

The author concluded by saying that while not denouncing drugs, he wished to reimpress the importance of rest, exercise, diet, water, hygiene, remedies which had withstood the test of time and which challenged the most searching investigation.

Common Sense in Treatment.—Dr. Alfred L. Loomis was requested by the President to open the discussion, Dr. Draper, who was to open the discussion, not being present. He said it seemed to him that the paper was an argument for the use of common-sense in the treatment of disease. While it was being read he recalled a paper which had been presented before the American Climatological Association at its meeting in Boston three or four years ago. In it was given the mortality-rate of pneumonia as it had occurred in the Massachusetts General Hospital during a period of seventy-five years under various plans of treatment. The author of the paper took into consideration the age of the patients, habits of life and surroundings prior to admission, and, as far as possible, all those conditions which would be likely to influence the results of treatment. At one time during the seventy-five years the antimony treatment of pneumonia prevailed, at another the blood-letting, at another the calomel, at another the let-alone plan, at another the antipyretic, and finally the antiseptic treatment prevailed, presenting the results in the form of a chart during the different decades when these several plans of treatment were in vogue. The chart, arranged on a similar plan to a temperature chart, showed, instead of a zigzag line, which one might expect, almost a straight line for the entire seventy-five years. This result had seemed to Dr. Loomis the strongest proof that a certain proportion of patients with pneumonia would recover, whatever kind of treatment they might be subjected to, while a certain proportion would die. In other words, there was a certain proportion of cases in which the death-blow took place at the beginning, and the result would not be modified in those cases, at least by treatment; between these two classes of cases there were a limited number where life might be saved by judicious management. He believed that every good physician, every careful observer, every intelligent man, as he grew older, became less and less attached to drugs. The more he saw of disease and the more he treated it, the more did he become convinced that the most reliable therapeutic agents were proper food, fresh air, exercise, rest, and water. The speaker was sometimes astonished, on carrying a patient safely through typhoid fever or some other form of acute disease, at the few medicines he had prescribed. About three years ago he read a paper before the State Medical Society in which he thought he had shown conclusively that ordinary use of antipyretics did harm rather than good. It seemed to him that when we studied the condition of our patient, the causes of his disease, and their immediate and ultimate effects, we would treat him rather than the disease, using, for the most part, such physiological remedies as the author had referred to. "I have sometimes thought that Dr. Baruch has gone a little 'crazy' on the use of water in his treatment of disease. Perhaps I am a little off on fresh air, climate, change of surroundings, and all that these imply. If we are enthusiasts the tendency is to favor one line of therapeutics more than another, however good or bad it may be; but the statements contained in the paper in regard to the treatment of disease by drugs I most heartily endorse."

Not Ready to Discard Drugs.—Dr. A. Jacobi said that Dr. Loomis was correct in the statement that he had been preparing what he should say, for he had been preparing himself the last half hour and had prepared himself so much indeed that he now had really nothing to say. He had taken notes but had said to himself, "Yes, that is well understood and everybody knows it; if not, everybody ought to know it, and may know it in the future." On the other hand, he had noted several things with which he could not agree, and while he admitted the former he would also defend the latter.

No sensible person would say to day that the whole of medical science or therapeutics consisted in prescription-writing, any more than that forty or fifty years ago the whole of medical science in certain parts of Europe consisted in diagnosis. While there might be a disposition on the part of some doctors, or doctors in some localities, at certain periods, to give too much attention to one branch of medical science, yet they must admit that diagnosis, pathology, prescription-writing, and the various other departments of medicine were necessary to make up the whole

It should also be remembered that as individual physicians we had to deal with individual cases of disease, although the tendency of that disease in the generality of patients was to get well. If the cases were left alone, the patient was kept in bed, supplied with fresh air, such diet as was appropriate, and given such hygienic surroundings as were desirable, it was true that unnecessary medicines could then only prove disturbing. However, now and then a medicine would certainly be required, if it were only for the purpose of, for instance, correcting the gastric secretions in fever. For such a reason hydrochloric acid, or even an antipyretic, might be indicated and prove useful. Each individual case must be treated according to its merits. It was all very well to bring statistics of, for instance, a thousand cases of pneumonia, which had been treated in different ways, but he did not believe we could learn by this means how to deal with individual cases of pneumonia.

He had understood that the author condemned venesection *in toto* in the treatment of pneumonia. He could not take this view even of this therapeutic procedure, for although it was seldom called for, yet there were now and then cases in which it alone would save the life of the patient. When the state of the circulation demanded venesection he then regarded this procedure just as much a physiological remedy as were diet, climate, water, etc.

He fully agreed with the author as to the impropriety of overdosing in the treatment of high temperature, but here again he must say that there were individual cases in which it was necessary to resort to the use of antipyretics. For instance, when the temperature was at 105° or 107° F., the stomach might refuse to absorb any nourishment whatever until that temperature had been reduced, as it could readily be by the use of certain drugs. He also agreed with Dr. Loomis that the older we get the more we were inclined to reduce the number of our medicines. The example of the German Pharmacopœia was worthy of our imitation in this regard. The number of remedies which that had included had gradually dwindled down to hundreds, where it had been thousands some years ago, yet he hoped that he would not become so old that he would drop all medicines. He wanted, for instance, his salicylic acid, to which the author had referred; his quinine, and a great many other excellent remedies in certain cases. He did not wish to be reduced simply to cold water, fresh air, climate, and diet, in the treatment, for instance, of diphtheria.

Unnecessary prescription-writing was bad, so was excessive eating, sitting in a draught, excessive bathing, etc.

Dr. George L. Peabody said that he agreed with the general drift of the communication, but in certain details he found himself somewhat at variance with it. There could be no doubt, he thought, that it was far better to resort to some such rational therapeutics as the paper had indicated than to symptomatic therapeutics which it had condemned in rather a wholesale way. Symptomatic therapeutics was simply no therapeutics in a large majority of cases. It was, in his opinion, a misnomer. Yet occasionally symptoms arose which were so urgent that they had to be treated merely as symptoms.

When it came to the author's proposition to treat all chronic diseases by, for instance, sending the patient to the mountains, this might be very well where the circumstances would permit; but how about the pale-faced anæmic or chlorotic maiden without means, and living in unfavorable environments? We were compelled to do what we could by prescribing medicines. He must also admit that personally he felt that iron was of considerable value in chlorosis, even where the circumstances would permit of carrying out hygienic rules.

He was also somewhat a believer in the efficacy of intestinal antisepsis. Not that he expected them to ferret out all the bacteria in typhoid fever and annihilate them at a blow, but they seemed to check intestinal fermentation and the development of gas, and promote digestion

As to discarding blood letting altogether, as he understood Dr. Baruch did, he was in agreement with D. Jacobi that there was certain cases of pneumonia, for instance, in which it was of benefit. Of course the old custom of bleeding in nearly every case, and even to the extent of producing syncope, should never be revived. Especially had he found that blood-letting was a life-saving agent in some cases of coal-gas poisoning.

He had already put himself on record as to the value of the full bath, or Brandt method of treatment of typhoid fever, and it was unnecessary for him to say that he disapproved of any modification or substitute; yet it was here like in the case of the pale-faced, chlorotic maiden who could not go to the mountains. Poverty sometimes made it impossible to apply the treatment in the most perfect way. Under these circumstances he had found the bed-bath a good substitute, though far inferior to the tub-bath.

Regarding the evil of symptomatic treatment or the abuse of prescription-writing, he regarded it as due largely to the ignorance of partially educated physicians, and believed it would not cease until the public demanded a higher grade of education on the part of the medical adviser, and showed its willingness to pay for the better service.

Dr. Baruch said, in conclusion, that the reason why he had written this paper was to be found in the statement of two of the speakers, namely, that as we grow older we resort less and less to drugs. Some thirty years ago this fact had been alluded to by a physician whom he had occasion to meet in consultation, and who told him that when he should have attained to riper experience he would not be so positive as to the exact action of certain medicinal agents. Dr. Baruch had warmly disputed this statement, but time had proven the correctness of the old physician's assertion. It was especially desirable that young men should be taught not to place too much reliance upon drugs.

He said that if he was "crazy" as to the use of water, there were a good many lunatics abroad in Germany and France, and some in this city, one of whom had spoken quite rationally while discussing the paper.

Regarding venesection, he said that he had only given the general opinion of the profession on the subject. There were some rare cases where he thought himself it was of benefit.

A Doctor with Experience Wanted.—One day, while mending the roof of his house, Chodja lost his balance and, falling to the ground, broke a rib. A friend of his went hurriedly for a Hakim (doctor). "Hakim, have you ever fallen from a roof and broken a rib?" was the first question Chodja asked the doctor. "Thank God, no," replied the Hakim. "Then go away at once, please," cried Chodja; "I want a doctor who has fallen from a roof and knows what it is."

The Bill of the National Quarantine Committee of the New York Academy of Medicine.

THE following is the final draft of the bill of the Committee on Quarantine of the New York Academy of Medicine, which is to be presented to Congress during its coming session :

A Bill to establish within the Treasury Department a Bureau of Public Health.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled :

Creating Sanitary Districts.

SECTION 1. That for the purposes of this Act the States and Territories of the United States be, and are hereby, grouped into districts, to be known as "The Sanitary Districts of the United States," as follows :

The Northern Sanitary District shall include the States of Illinois, Indiana, Iowa, Michigan, Minnesota, Ohio, Wisconsin.

The Northeastern Sanitary District shall include the States of Connecticut, Massachusetts, Maine, New Hampshire, New York, Rhode Island, Vermont.

The Northwestern Sanitary District shall include the States of Idaho, Montana, North Dakota, Oregon, Washington, and the Territory of Alaska.

The Eastern Sanitary District shall include the States of Delaware, Maryland, New Jersey, Pennsylvania, Virginia, West Virginia, and the District of Columbia.

The Western Sanitary District shall include the States of California, Nevada, and the Territories of Arizona and Utah.

The Southern Sanitary District shall include the States of Arkansas, Alabama, Kentucky, Louisiana, Missouri, Mississippi, Tennessee.

The Southeastern Sanitary District shall include the States of Florida, Georgia, North Carolina, South Carolina.

The Southwestern Sanitary District shall include the State of Texas and the Territories of Indian Territory, New Mexico, Oklahoma.

The Central Sanitary District shall include the States of Colorado, Kansas, Nebraska, South Dakota, Wyoming.

SEC. 2.. That there shall be established in the Treasury Department, under the direction and supervision of the Secretary thereof, a Bureau of Public Health, to consist of a commission of fifteen, of whom eleven shall be appointed by the President, by and with the advice and consent of the Senate, as follows, viz. : One Medical Commissioner from each of the "Sanitary Districts of the United States," provided in section one of this Act, and two commissioners at large ; the compensation of the appointed commissioners, when actually engaged in the performance of their duties under this Act, shall be ten dollars per diem and reasonable expenses. The other four members of the Commission shall be the Surgeon-General of the Army, the Surgeon-General of the Navy, and the Supervising Surgeon-General of the Marine Hospital Service, and an officer, learned in the law, detailed by the Attorney-General from the Department of Justice ; these four members shall receive no compensation.

SEC. 3. That the members of the Commission shall meet at such time and place as may be designated by the Secretary of the Treasury, and organize by the election, from their own number, of a president who shall be one of the members at large, and who shall receive five dollars per diem, in addition to the ten dollars per diem provided in the last section, when actually engaged in the performance of his duties under this Act. The other member-at-large shall be Vice-President of the Commission who shall perform the duties of President when the latter is unable to do so. The Commission may appoint a Secretary not one of its number, and fix his salary at a sum not exceeding three thousand dollars annually. The Commission shall thereafter meet annually, at Washington, on the first Tuesday of October, and at such other times and places as the President of the Commission, with the approval of the Secretary of the Treasury, may designate. At the first meeting of the Commission, the members appointed from sanitary districts shall be divided into three classes of three members each, and they shall determine by lot to which class each member shall belong ; the first class shall serve for one year, the second class for two years, and the third class for three years ; the two members at large shall serve, one for three years, and the other for six years and they shall determine by lot their respective terms of service ; thereafter the terms of service of each member appointed from a sanitary district shall be for three years, and each member appointed at large shall be for six years ; all appointments to fill vacancies shall be for the unexpired term.

SEC. 4. That there shall be an Executive Committee of the Commission, consisting of its President, the Surgeon-General of the Army, the Surgeon-General of the Navy, and the Supervising Surgeon-General of the Marine Hospital Service, and the officer detailed by the Attorney-General. The Commission shall from time to time prescribe the duties of the Executive Committee, and may make all needful rules and regulations for its own control and for the guidance and discipline of all its officers and employees, and shall establish all rules and regulations for the government of national sanitation in all of its foreign and interstate relations, and special departments in the enforcement of the provisions of this Act.

SEC. 5. That when, in the opinion of the President of the Commission, the interest of the public health would be promoted by a conference of the Commission with the State Boards of Health of the several States, or of any sanitary district or districts, he is hereby authorized to invite, with the approval of the Secretary of the Treasury, said State Boards of Health, or such number thereof as he may designate, each to delegate one of its members to meet the Commission in conference at such time and place as he may appoint ; the President of the Commission shall be the President, and the Secretary of the Commission shall be the Secretary of any such conference ; the delegate in attendance upon the conference from each State Board of Health shall be entitled to receive reasonable compensation for expenses for a session not exceeding three days, to be paid on vouchers provided by the Secretary of the Treasury.

SEC. 6. That the duties of the Bureau of Public Health shall be to collect and diffuse information upon all matters affecting the public health : to advise the several departments of the Government, the executives of the several States, and all health authorities on all questions submitted to it, or whenever in the opinion of the Bureau such advice may tend to the preservation and improvement of the public health ; to secure the best sanitary condition of vessels from foreign ports ; to prevent the introduction of contagious and infectious diseases into the United States, and their spread from one State into another ; to co operate with and aid State and municipal health authorities in the execution and enforcement of rules and regulations to suppress contagious and infectious diseases ; and, in general, to be the medium through which the General Government shall adopt such measures and take such action as will most effectually protect and promote the health of the people of the United States.

SEC. 7. That the Bureau of Public Health may, with the approval of the Secretary of the Treasury, make investigations, both in the United States and, if necessary, in foreign countries, into the nature, origin, and prevention of contagious, epidemic, and other diseases, as well as the causes and conditions of particular outbreaks of disease in the United States, and may employ such experts and for such time and in such manner as the exigencies of the service may require. When requested by

the Bureau of Public Health, and when the same can be done without prejudice to the public service, the President may detail officers from the several Departments of the Government for temporary duty to act under the direction of said Bureau, to carry out the provisions of this act; and such officers shall receive no additional compensation except for actual and necessary expenses incurred in the performance of such duties.

SEC. 8. That as soon as practicable after this act shall take effect the Commissioners appointed from the Sanitary Districts shall each in his respective District examine all the means and measures employed by State, municipal, and other health authorities to prevent the introduction of contagious and infectious diseases into the United States, and their spread from one State or Territory into another, and report the fact to the Bureau of Public Health, and the Commission shall embody these facts in a report to the Secretary of the Treasury, who shall transmit the same to Congress with such recommendations as he may deem important. Thereafter each Commissioner shall annually, on or before October 1st, report upon the measures employed, with the result, in his Sanitary District to prevent the introduction, origin, and spread of contagious and infectious diseases, and the Commission shall embody the facts in its annual report to the Secretary of the Treasury.

SEC. 9. That it shall also be the duty of the Bureau of Public Health to obtain information of the sanitary condition of foreign ports and places from which contagious and infectious diseases are or may be imported into the United States, and to this end the consular officers of the United States at such ports and places as shall be designated by the Bureau of Public Health shall make to said Bureau weekly reports of the sanitary condition of the ports and places at which they are respectively stationed, according to such forms as said Bureau may prescribe; and the Bureau of Public Health shall also obtain, through all sources accessible, including State and municipal sanitary authorities throughout the United States, weekly reports of the sanitary condition of ports and places within the United States; and shall also, as far as it may be able, by means of the voluntary co operation of State and municipal authorities, of public associations, and private persons, procure information relating to the climatic and other conditions affecting the public health, and the existence of epidemic, endemic, and other diseases; also statistics relating to marriages, births, and deaths.

SEC. 10. That the Commission shall prepare, publish, and transmit to the medical officers of the Army, Navy, and the Marine Hospital Service, to collectors of customs, and to State and municipal health officers and authorities, weekly abstracts of the consular sanitary reports and other pertinent information received by the Bureau of Public Health.

SEC. 11. That whenever any department of Government or the Executive of any State or Territory, or the authorities of the District of Columbia, or the health authorities of any State or municipality, shall request information from the Bureau of Public Health in regard to any matter pertaining to the protection or promotion of the public health, said Bureau shall promptly furnish such information as it may have on record, together with any necessary or pertinent advice; and whenever information shall be received by the Bureau which the interests of the public health require should be promptly communicated to any department of the Government, or to any State or municipal officer, such information shall be forthwith furnished to the respective department or officer.

SEC. 12. That the Commission shall take such action by correspondence or conference as will tend most effectually to secure the co-operation of State, municipal, and local boards of health in establishing and maintaining an efficient and accurate system of notification of the existence and progress of contagious and infectious diseases in the United States, and said Commission shall also by co-operation with the proper health authorities of foreign nationalities and municipalities endeavor to extend to the United States a reliable system of international notification of the existence and progress of such diseases as cholera, yellow fever, typhus fever, and small-pox.

SEC. 13. That the Bureau of Public Health shall make such rules and regulations, with the approval of the Secretary of the Treasury, as are necessary to be observed by vessels at the port of departure and on the voyage, where such vessels sail from any foreign port or place, to secure the best sanitary condition of such vessel, her cargo, passengers, and crew, which shall be published and communicated to and enforced by the consular officers of the United States. None of the penalties herein imposed shall attach to any vessel, or owner or officer thereof, until a copy of this act, with the rules and regulations made in pursuance thereof, has been posted up in the office of the consul or other consular officer of the United States for ten days, in the port from which said vessel sailed; and the certificate of such consul or consular officer over his official signature shall be competent evidence of such posting in any court of the United States.

SEC. 14. That the Bureau of Public Health shall, with the approval of the Secretary of the Treasury, from time to time issue to the consular officers of the United States, and to the medical officers serving at any foreign port, and otherwise make publicly known, the rules and regulations made by it, and approved by the Secretary of the Treasury, to be used and complied with by vessels in foreign ports for securing the best sanitary condition of such vessels, their cargoes, passengers, and crew, before their departure for any port in the United States, and in the course of the voyage, and all such other rules and regulations as shall be observed in the inspection of the same on the arrival thereof at any quarantine station at the port of destination, and for the disinfection and isolation of the same, and the treatment of cargo and persons on board, so as to prevent the introduction of cholera, yellow fever, or other contagious or infectious diseases.

SEC. 15. That it shall be unlawful for any merchantship or other vessel from any foreign port or place to enter any port of the United States except in accordance with the provisions of this act, and with such rules and regulations of State and municipal health authorities as may be made in pursuance of, or consistent with, this act; and any such vessel which shall enter, or attempt to enter, a port of the United States in violation thereof shall forfeit to the United States a sum, to be awarded at the discretion of the court, not exceeding $5,000, which shall be a lien upon said vessel, to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States district attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

SEC. 16. That any vessels at any foreign port clearing for any port or place in the United States shall be required to obtain from the consul, vice-consul, or other consular officer of the United States at port of departure, or from the medical officer where such officer has been detailed for that purpose, a bill of health, in duplicate, in the form prescribed by the Secretary of the Treasury, setting forth the sanitary history and condition of said vessel, and that it has in all respects complied with the rules and regulations in such cases prescribed for securing the best sanitary condition of the said vessel, its cargo, passengers, and crew; and said consular or medical officer is required, before granting such duplicate bill of health, to be satisfied that the matters and things stated therein are true; and for his services in that behalf he shall be entitled to demand and receive such fees as shall by lawful regulation be allowed, to be accounted for as required in other cases.

The President, in his discretion, is authorized to detail any medical officer of the Government to serve in

the office of the consul at any foreign port for the purpose of furnishing information and making the inspection and giving the bills of health hereinbefore mentioned. Any vessel clearing and sailing from any such port without such bill of health, and entering any port of the United States, shall forfeit to the United States not more than $5,000, the amount to be determined by the court, which shall be a lien on the same, to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States district attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

Sec. 17. That it shall not be lawful for any vessel to enter any port of the United States to discharge its cargo, or land its passengers, except upon a certificate of the health officer at such quarantine station certifying that said rules and regulations have in all respects been observed and complied with, as well on his part as on the part of the said vessel and its master, in respect to the same and to its cargo, passengers and crew; and the master of every such vessel shall produce and deliver to the collector of customs at said port of entry, together with the other papers of the vessel, the said bills of health required to be obtained at the port of departure, and the certificate herein required to be obtained from the health officer at the port of entry; and that the bills of health herein prescribed shall be considered as part of the ship's papers, and when duly certified to by the proper consular or other officer of the United States, over his official signature and seal, shall be accepted as evidence of the statements therein contained in any court of the United States.

Sec. 18. That the Commission, with the approval of the Secretary of the Treasury, shall have authority to forbid entry of vessels from ports known or suspected to be infected with cholera, yellow fever, small-pox, or other declared quarantinable disease into all minor approaches to a port of entry or into any inlet or place within the jurisdiction of the United States not provided with a complete quarantine plant, in order to compel such vessels to be subjected to maritime sanitation at the quarantine station equipped for that purpose and commanding the scope of region in question.

Sec. 19. That on the arrival of an infected vessel at any port not provided with proper facilities for treatment of the same, the Commission may remand said vessel, at its own expense, to the nearest national or other quarantine station where accommodations and appliances are provided for the necessary disinfection and treatment of the vessel, passengers, and cargo; and after treatment of any infected vessel at a national quarantine station, and after certificate shall have been given by the United States quarantine officer at said station that the vessel, cargo, and passengers are each and all free from infectious disease, or danger of conveying the same, said vessel shall be admitted to entry to any port of the United States named within the certificate. But at any ports where sufficient quarantine provision has been made by State or local authorities, the Commission may direct vessels bound for said ports to undergo quarantine at said State or local station.

Sec. 20. That when cholera or yellow fever shall be ascertained by the Bureau to exist in any port or place within any one of the United States or Territories, or the District of Columbia, in such form as threatens its spread to other ports and places within other States, or Territories or the District of Columbia, by means of vessels and vehicles engaged in the transportation of goods or passengers between two or more States, or States and Territories, and the District of Columbia, whether by land or water, the Commission is authorized to adopt such rules and regulation with the approval of the Secretary of the Treasury, as, in its judgment, may be necessary in order to prevent the spread thereof from one State or Territory to another or to the District of Columbia, and to employ such inspectors and other persons as may be necessary for the purpose aforesaid; the Commission may select suitable localities for establishing stations on rivers and other lines of inter State commerce and travel by railroads, and may cause to be erected necessary temporary buildings for the disinfection of passengers, baggage, cargoes, vessels, and vehicles, and may enforce such rules and regulations relating thereto as may have been prescribed therefor; it shall be lawful for the Commission to confer upon any local health officer or health board within or near the locality where his or its authority is exercised, power also to enforce the provisions of this act and any rules and regulations made in pursuance thereof; and any person who shall knowingly disobey or violate any order, rule, or regulation made pursuant to the authority herein conferred shall be deemed guilty of a misdemeanor, punishable by a fine of not less than five hundred dollars, and by imprisonment for a period of not less than one year.

Sec. 21. That the Commission shall, under the direction of the Secretary of the Treasury, co-operate with and aid State and municipal health authorities in the execution and enforcement of the rules and regulations of such authorities, and in the execution and enforcement of the rules and regulations made by the Commission and approved by the Secretary of the Treasury to prevent the introduction of contagious or infectious diseases into the United States from foreign countries, and into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia; and all rules and regulations made by the Commission and approved by the Secretary of the Treasury shall operate uniformly and in no manner discriminate against any port or place; and at such ports and places within the United States as have no quarantine regulations under State or municipal authority, where such regulations are, in the opinion of the Commission, necessary to prevent the introduction of contagious or infectious diseases into the United States from foreign countries, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, and at such ports and places within the United States where quarantine regulations exist under the authority of the State or municipality which, in the opinion of the Commission, are not sufficient to prevent the introduction of such diseases into the United States, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, the Commission shall, if in its judgment it is necessary and proper, make such additional rules and regulations as are necessary to prevent the introduction of such diseases into the United States from foreign countries, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, and when said rules and regulations have been made they shall be promulgated by the Commission and enforced by the sanitary authorities of the States and municipalities, where the State or municipal health authorities will undertake to execute and enforce them; but if the State or municipal authorities shall fail or refuse to enforce said rules and regulations, the President shall execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and may detail or appoint officers for that purpose.

Sec. 22. That whenever the proper authorities of a State shall surrender to the United States the use of the buildings and disinfecting apparatus at a State quarantine station, the Commission shall cause an examination thereof to be made by its own members or by a competent person, or persons, and if the said station, buildings, and disinfecting apparatus be found adapted to the purposes of a quarantine, and the Commission approve of their use as such, the Secretary of the Treasury shall be authorized to receive them, and to pay a reasonable compensation to the State for their use.

SEC. 23. That all orders, rules, and regulations of the Bureau of Public Health relating to Sanitation in any branch of the Public Service, or to prevent the introduction of contagious and infectious diseases into the United States, and their spread from one State or Territory into another State or Territory, or the District of Columbia, through or by means of any branch of the Public Service, the medical officers of such Service shall execute such orders, rules, and regulations, and to this end the Surgeon-General of the Army shall perform all such duties in respect to the Army, the Surgeon-General of the Navy shall perform all such duties in respect to the Navy, and the Surgeon-General of the Marine Hospital Service shall perform all such duties in respect to quarantine and quarantine regulations which are provided by this act.

SEC. 24. That whenever the Commission shall certify to the President, and it shall appear to his satisfaction that, by reason of the existence of cholera or other infectious or contagious diseases in a foreign country, there is serious danger of the introduction of the same into the United States, and that notwithstanding the quarantine defence this danger is so increased by the introduction of persons or property from such country that a suspension of the right to introduce the same is demanded in the interest of the public health, the President shall have power to prohibit, in whole or in part, the introduction of persons and property from such countries or places as he shall designate, and for such period of time as he may deem necessary.

SEC. 25. That the Bureau of Public Health shall make an annual report of its operations to the Secretary of the Treasury, who shall transmit the same to Congress, with such recommendations as he may deem important to the public interests; and said report, if ordered to be printed by Congress, shall be done under the direction of the Board; and that all mail matter of whatever class relative to the Bureau of Public Health and its duties, and addressed to its secretary and indorsed "Official Business, Bureau of Public Health," shall be transported free of postage; and if any person shall make use of any such indorsement to avoid the payment of postage on his private letter, package, or other matter in the mail, the person so offending shall be guilty of a misdemeanor, and be subject to a fine of five hundred dollars, to be prosecuted in any Court of competent jurisdiction.

SEC. 26. That there shall be, and hereby is, appropriated, out of any moneys in the Treasury not otherwise appropriated, the sum of one million dollars, to be expended, or so much of the same as may be necessary from time to time, under the direction of the President and according to his discretion, to meet emergencies arising in the execution of the provisions of this act.

SEC. 27. Repealing Section.

Victims to Duty.—*The Lancet* says: "One more name has to be added to the roll of those young members of our profession who have perished on the threshold of a promising career, while actually engaged in the attempt to save the lives of others. We regret to learn that Mr. W. F. Lucas, casualty medical officer to the Middlesex Hospital, died in that institution on Monday last from diphtheria contracted in the discharge of his duties." *The Boston Medical and Surgical Journal* adds this: "Every physician knows many instances where his professional comrades have fallen by his side, struck down by infectious fevers or septic absorption received at the bedside of a patient. Notable instances have recently brought this peril afresh to our minds. A contemporary journal, in the last issue, records the death of a practising physician who caught the infection of yellow fever from a patient whom he was attending, and also the death of a promising young doctor to whom the infection of typhoid fever was communicated from a child patient at the New York Hospital. Last week it was our melancholy duty to report the death of a brilliant young physician of unusual qualities of mind and heart, who caught diphtheria from a patient at the Boston City Hospital."

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE PATHOLOGICAL SOCIETY—DR. PAVY'S ADDRESS—HE REJECTS THE GLYCOGENIC THEORY OF DIABETES—EXHIBITION OF SPECIMENS — THE CLINICAL SOCIETY — MR. HULKE'S ADDRESS—SURGERY OF THE ALIMENTARY CANAL —MR. ROBSON'S CASES OF ADHESIONS RELIEVED BY OPERATION — DISCUSSION ON THESE CASES — MALIGNANT TUMORS OF LARGE INTESTINE—FELLOW OF THE COLLEGE OF SURGEONS—KEELEY'S LAW PROCEEDINGS—CHOLERAIC DIARRHŒA.

LONDON, October 14, 1893.

THE session of the Pathological Society was opened on Tuesday evening, when Dr. Pavy, the new president, delivered an address in which he urged the importance of chemical pathology and assured those who would take up research into this department of an abundant harvest. The three fundamental properties of protoplasm, he said, were: *a*, It started from previously existing matter; *b*, under suitable conditions it was endowed with power to shape itself into some determinate form; *c*, it would bring about chemical changes in matter in its neighborhood. Modifications of the surroundings of protoplasm could give rise to deviations which are within the province of pathology. He then dealt with the case of diabetes as an instance, for here we have elimination of sugar in a manner that should not occur. In normal conditions carbohydrates taken into the system are lost sight of, but in diabetes pass off in the urine in proportion to the amount ingested. The common belief in the conveyance of sugar to the capillaries for destruction, Dr. Pavy declared, leads into darkness, and the accepted physiology, he said, is untenable. Study and experiment convinced him that the glycogenic doctrine is wrong. The liver is not charged with sugar, holds no more than other parts—not so much as some. Blood coming from the liver contains no more than that going to it; in fact, after food, the portal blood is richer in sugar than that in the hepatic vein. The normal constitutional blood contains 0.6 to 1.0 per 1,000 of sugar; while we often find 5 per 1,000 or more in the portal blood. To the cells of the villi and of the liver he attributed a "protoplasmic power" (whatever that may be) by the exercise of which carbohydrates are converted into proteids and through them into fat, and the failure of such conversion results in diabetes.

After the address specimens were exhibited and commented on of congenital deformity of the lip; pyonephrosis of the kidney with double ureter; congenital interruption of the duodenum with dilatation; a similar interruption at the termination of the jejunum, which was greatly distended; a congenital deficiency in the middle of the œsophagus, in which the pharynx ended blindly.

Mr. Hulke, as president, opened the session of the Clinical Society on the 13th inst. with a brief address in which he glanced at the progress made in the several departments of medicine. Referring to the early volumes of the "Transactions" and his own early experience, he pointed out how imperfectly asepsis was then understood by a few and how completely ignored by the majority, in proof of which he gave a realistic description of the state of one of the great hospitals at that time. He then urged that the strictest attention to method, and the most scrupulous observance of detail were nearly if not quite as important as the choice of an agent. He then directed attention to the last few volumes of the "Transactions" as containing a number of cases of surgical measures for treating diseases and injuries of the alimentary canal. He thought the serious mortality of some of these operations was often due to the late period to which they were postponed, and this particularly in cases of gradual but progressive narrowing of the tube. As to excision of the

vermiform appendix, he held that in many instances it was better to freely open, empty, and drain the abscess than to attempt a methodical removal of the appendix. The address, which was listened to with the attention due to Mr. Hulke's position and experience, was a very appropriate prelude to the papers brought forward after its conclusion.

Mr. Mayo Robson then gave an account of two cases of dilatation of the stomach dependent on pyloric adhesions. One case seemed to have arisen from gall-stones, the other from gastric ulcer. He brought forward these cases because it is not generally recognized that dilatation of the stomach may be cured by separating such adhesions, though it is well known that serious symptoms may be produced by them. He laid special stress on severe abdominal pain and visceral disability being produced by adhesions and cured by their separation, and was disposed, when medical treatment had been fully tried without benefit, to open the abdomen and then proceed as might be found desirable. He thought many cases called neuroses are due to such conditions as distorted or tied appendix, displaced ovaries or tubes, or both, omental adhesions in great variety, producing visceral distortion, all cases which may be cured or relieved by laparotomy without any mutilation of viscera.

The President congratulated Mr. Robson on his success, but thought that adhesions might be easy to separate, but that it would be difficult to prevent their recurrence, and when they had been caused by ulceration they might be the only barrier to perforation and so their separation would be perilous.

Dr. F. Roberts attached much importance to adhesions, both in the chest and abdomen. His students regard it as one of his fads. He had not seen them treated by surgery. He had met with cases, however, cured by laparotomy when the supposed cause was not found, and mentioned one he had diagnosed as gall-stones, in which the surgeon who operated found nothing, but the patient was cured.

Dr. H. White mentioned an autopsy he had performed on a case supposed to be malignant, but which was due to a gall-stone ulcerating through the pylorus, and would probably have been saved by an operation at an earlier period. He also mentioned a case of typhlitis which recovered under ordinary treatment, but some months later ovarian symptoms led to a suspicion that the appendix was adherent to the ovary. Exploration showed the suspicion to be correct. Appendix and ovary were removed and all symptoms disappeared.

Mr. P. Gould enquired how the author made out that there was no narrowing of the pylorus, and remarked that as cases were cured by operation when no adhesions were found, it was clear the symptoms did not always depend on their existence. Moreover sometimes it is desirable to cause rather than prevent adhesions—as for instance in movable kidney.

Mr. Robson in reply said there was severe peritonitis in both his cases; he grasped the pylorus to ascertain if it was enlarged and rolled it between his fingers to feel the internal surfaces glide over each other and this fairly indicated the state of the passage; if thickened and hard the pylorus might resemble malignant growth; to prevent recurrence of adhesions he placed the parts at some distance from each other when practicable, carefully stopped bleeding and wiped them dry after applying antiseptics, and so reduced the risk as far as possible. In operating for gall-stones he thought the separation of adhesions often had more to do with relief than removing the stone. Impacted gall-stone is sure to set up local peritonitis, and if he found none he scarcely ever found the stone. He had seen cases recover in which only a little ascitic fluid was let out, but offered no explanation, though he expected these curious cases would some day be explained.

Mr. W. Edmunds then read two cases of excision of malignant tumor from the large intestine in men of fifty and fifty-four respectively. Both remain well, one fifteen months the other four years after the operation. Halsted's method was preferred to Senn's, and seemed to find favor with the other surgeons present. The liquid state of the fæces in right colotomies was commented on, and Mr. Edmunds remarked that the function of the large intestine was perhaps to convert liquid into solid fæces. In support of this Mr. Robson said in a case in which he found a malignant tumor in the ascending colon which he was unable to remove, he brought up the distended ileum and opened it after twelve hours. The escape of liquid fæces was such a trial to the patient that a month afterward the abdomen was again opened and the ileum fixed to the sigmoid flexure, and the patient has remained in such good health as to decline further interference.

Some of the Fellows of the Royal College of Surgeons are elated at the triumph they think the Association of Fellows have obtained over the obstructives of the Council. The council have at length appointed a committee to consider the desirability of convening meetings of Fellows apart from members, and if deemed desirable to formulate a scheme. The Fellows are but a small body while the members number thousands. The Association of Fellows need scarcely be feared—it consists for the most part of Fellows who subscribe their guinea, but leave all work to their committee. One of them confessed to me that at a late meeting only one non-official Fellow was present.

You may be interested to hear that Dr. Keeley has withdrawn from the actions for libel he commenced against the medical journals here, on account of their criticisms of his alleged cure for the drink crave.

There has been an outbreak of choleraic diarrhœa at Greenwich workhouse which at first caused some anxiety, as comma bacilli were found, but cultivations of these failed and so bacteriologists tell us the disease was not true cholera. Clinicians would tell us as much because rice-water evacuations and other symptoms of cholera were absent and the mortality was very low.

OUR BERLIN LETTER.

THE NATURAL SCIENTISTS' MEETING—PROFESSOR HIS REGARDING THE MANNER OF BUILDING UP OF THE NERVOUS SYSTEM—PROFESSOR STRÜMPELL ON ALCOHOLISM—PROFESSOR HÜPPE ON THE CAUSES OF FERMENTATION AND INFECTIOUS DISEASES.

BERLIN, October 1, 1893.

THE sixty-fifth anniversary of German Scientists and Physicians has just taken place at Nürnberg. Last year the meeting was postponed owing to the prevalence of cholera, and the holding of this meeting looked also rather doubtful, owing to the existing cholera epidemic. It has taken place, however, and some of our greatest scientists met and discussed the most important problems of the day. It was so arranged that among the twenty different sections each and every branch of medicine and science was amply discussed. The enormous amount of literature prevents me from giving you what I consider the most important items. I shall promise, however, to give you all forthcoming important points when officially printed.

The first paper was by Professor His (Leipsic) on the "Construction of our Nervous System."

He said every nerve-fibre emanating from a central organ comes as a continued axis from a nerve-cell. The end coming from the cell runs as a rule free, and is surrounded by a bundle of branching nerve ends or nerve-fibres. The majority of the nerve-cells, besides sending out the never-fibre, which is a direct continuation of this nerve-cell, gives out a so-called protoplasma-continuations, or "dandriten," which terminates singly. The sensory fibres do not shoot from cells in the brain or spinal cord, but are bound together with the so-called spinal ganglion, with which they appear to be allied laterally.

The central portion of the sensory fibre (nerve) divides

on entering the marrow into two, and later into more fibres, which, so far as they can be followed, continue singly; and in the same way the periphery of the sensory fibre ends in free fibres. Accordingly the nervous system is composed of numerous fibres, divided, separated, and ending in cells of so called neuronen.

In the gray matter of the brain and spinal cord these endless branches unite to form a thick felt, but no network. The continual relationship of all the nerve elements within the gray substance, which has hitherto always been accepted, does not exist. The coaptation is in reality not marked, as each single fibre proves itself distinct and independent of the others.

This tends to prove that within the gray substance of the marrow the transmission of the current is brought about from one system to the other through intermediate transmitters.

At the same time there exist certain anatomical peculiarities which tend to regulate currents transmitted.

We find that several end fibres seem to be interwoven, and seem to act in some way on the one hand, while we find that the end-fibres of another bundle of nerves seem to me united basket-like on the other hand. But the nerve-cell seems to be the point of union of all currents transmitted. The further propagation of the current seems to be in the direction of the nerve-fibre emanating from the nerve-cell.

This we find in the motor centres of spinal cord and the pyramidal cells of the brain. Opposed to these latter appear the dandoide cells, which are like a collection of roots, and seem to gather currents from all directions, and then transmit them to the nerve-cell.

Of great importance appear the collateralen in which a single nerve is able to control a large area by means of diffused cell areas. It is only since we know the course of sensory fibres, which on traversing different tracts toward the brain have numerous side branches which connect with the motor and sensory centres of the spine, and thus it is that reflex action can be caused or sensation felt through one and the same nerve.

Professor Strümpell (Erlangen) read a paper on the alcohol question from a medical stand-point. He detailed the popular and legal aspects of the alcoholic question, giving the subject of crime considerable weight. He cited the ideas of the connection of both, and believed crime to be the cause of alcoholic debaucheries. Of 1,130 people sentenced for crime in 1889, in Germany, 750 were so called drinking people, and 150 habitual drunkards; the other 600 went on periodical sprees. Popularly it is believed that beer contains an enormous quantity of nutrition. Let us inquire into this by comparing the price of food with drink: If a Bavarian workman drinks 4 litres of beer daily, equivalent to 5 pints, he receives in round numbers about two hundred and forty grammes carbohydrates and 32 grammes albuminoids. If he consumes bread costing one mark, he receives 2,000 grammes carbohydrates and 250 grammes of digestible albumin. Here can be seen the fallacy of the workman in giving almost one-sixth of his wages for beer daily.

Hundreds of students consume one to one and one-half mark daily of beer, and thousands of apparently poor people would suddenly be enriched if a check to the sale of beer were suddenly given. Physicians find that next to tuberculosis—lues—chronic alcoholism is the most wide-spread disease. As in chronic lead-poisoning, there is in alcoholism a slow but constant accumulative effect until the disease suddenly appears very vigorously. In lead poisoning we find paralysis of the hands; in alcoholism cardiac paralysis, diabetes, and gout, depending on the peculiar predisposition of the individual.

But this condition does not only come when the individual is an habitual drunkard, but also when the individual would resent any reference to his being addicted to liquor. In acute alcoholic poisoning we have a weakening of the nervous system, especially manifest in the motor nerves, in the irregular gait, and the difficult articulation.

But chronic alcoholism manifests peculiar neurotic disturbances, as polyneuritis, for example, and the well-known delirium tremens. But the latter is not very common, save in large cities, among laboring classes imbibing whiskey excessively. Besides the nerves, the stomach and intestines are the next to suffer, and in consequence are unable to perform their required functions because of the irritation caused by the alcohol. Very severe complications arise when alcohol is distributed into the circulation, reaching the capillaries, causing cirrhotic conditions in the liver, heart, and kidneys.

Certain detrimental actions of whiskey have caused beer to be the substitute; but again beer can act harmfully because of the large quantities imbibed, and as an abnormal quantity of food is eaten it sometimes happens that more food enters the nutrient cells than they require, giving, instead of nutrition, a balance of fat. And this latter is the real poisoning results of alcohol. Especially is this true with the kidneys, when large quantities of fluid are imbibed.

An acute alcoholic nephritis is usually caused by chronic alcoholism, and, in other cases slow alcoholic poisoning gives rise to gout, diabetes, and fatty enlargement. Although the last-named diseases are caused by other influences, still the cases caused by alcohol are so numerous as to give cause for alarm and for action on the part of the physician. The family physician should see to it that excessive drinking be not tolerated, and he should prohibit the use of the same in children. Here the author gave numerous instances of blame on the part of parents in feeding children with alcohol.

In the last meeting Professor Hüppe (Prag) read a paper on the "Causes of Fermentation and Infectious Diseases, and their Relationship to Energy." The paper gave an outline of the older ideas of cause and effect, in which a certain something was called the cause, and the disease the effect. To day we recognize the specific causes of disease as described from a bacteriological stand-point. We have now learned that zygomenic, chromogenic, pathogenic bacteria are all widely different one from the other.

The speaker mentioned the fact that an Algerian sheep, although immune against a certain quantity of anthrax, will, however, succumb to an increased dose of same. The chicken will die after a large quantity of chicken-cholera germs are introduced, whereas the guinea pig will die after a very small inoculation, which would not affect a chicken. The dog will succumb to a large quantity of tubercle bacilli, whereas he will not react against small quantities. So we find it to be a question of quantity—not quality. Example: Ordinary milk will turn at the presence of lactic ferment, but it will require a large amount to completely sour the milk and keep up an active fermentation. From what he said he concluded with the remark that in order that infectious diseases or infections shall take place there must be some disturbances in the physiological functions in order to make room for pathogenic functions.

Whortleberry Leaves in the Treatment of Diabetes.—Dr. R. Weil (*Hospitals-Tidende*, No. 7, 1893) recommends whortleberry leaves in diabetes mellitus, as an efficacious and uninjurious remedy. They should be gathered before fruit-bearing sets in. Dr. Weil learned their use from a peasant. Two handfuls of the leaves are boiled with two quarts of water down to a quart. He now employs the extract in the form of pills, each containing 12 ctgr. (2 grs.), which corresponds to 12 gm. (3 dr.) of the leaves. First one pill three times a day is taken, after which they may be gradually increased in quantity to five pills three times a day. In the writer's patients he has observed an extraordinarily prompt and lasting action. The quantity of sugar can only be determined by polarization or fermentation, as, after using the remedy for some time, the urine contains certain reducing substances.—PRITCHARD.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending October 28, 1893.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	33	20
Scarlet fever	76	4
Cerebro-spinal meningitis	4	4
Measles	88	2
Diphtheria	187	45
Small-pox	7	2
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Hospital Accommodation on the Man of War "New York."—The *Brooklyn Eagle* very pertinently says: "Her solitary and monumental defect is in the fact of the grossly and grotesquely inadequate accommodations for the care of the wounded, the sick, or the suffering, whether from causes of war or of peace. The ship's hospital is on the third deck from the top, called the berth-deck, at the extreme bow or forward part of the ship. The dimensions are miserably small. The room is an irregular triangle, twenty feet on its longest side, and fifteen and twenty on its two other sides. In it there is space to swing only two hammocks or sick-cots, and the place is so surrounded by some of the operative machinery of the ship as will render it in action or in motion a constant centre of noise of the most intolerable kind to the sensibilities of any patient. There are two mammoth steel tubes, technically called hawse-pipes, at the end of this sick-room. Through them by machinery run the anchor chains or cables of the ship. These chains are as large in size as a man's leg and of very great length. The noise made by these chains in operation is as great as that of a boiler factory, and in volume equal to ten calliopes. Right in front of this hospital or sick-bay is the torpedo room. All the work in using torpedoes will be distinctly audible in the hospital, and the effect of such noise and distraction can be readily imagined. The hospital is the only passageway to the torpedo room from the rest of the ship. The blunder of placing the hospital where it is, and the miserably small accommodations for hospital purposes, are a blot on naval construction, a parody on medical science, and an outrage on humanity. This blot, if it is not removed, will grow from a reflection on naval construction into an indictment and a shame on naval administration. If Hilary A. Herbert, the secretary of the navy, or William McAdoo, the assistant secretary of the navy, who are sensible and humane laymen, could see this abomination just as it is, their sleep would be tormented with reproaches until they gave orders for its reform and saw that the orders were carried out. The bureau of medicine and surgery of the navy cannot possibly approve of such a condition of things. If it is aware of them, it must, from the commonest premises of science and of decency, have protested against them. If its protest has been ignored, the shame for that fact must be due to the absence of any representative of the medical department of the navy from the board whose authority in the construction of vessels of war is final."

The Work of Medical Missionaries.—"We would be untrue," says *The Lancet*, "to one of our most honorable traditions if we failed to bring under the notice of the profession the noble work achieved from time to time in the far East, in Equatorial Africa, and indeed in all the remoter haunts of retrograde humanity, by the yearly augmenting band of missionary pioneers who are also duly qualified medical men. Now it is in the interior or on the littoral of China, now in the hill country round Lake Nyassa, that we hear of the progress made by these devoted men in elevating the savage or benighted populations to the standards of the West. No sooner does one of them sink in some generous enterprise than another fills his place and carries on the work to be in turn transmitted to an equally well-inspired successor. Recent mails have been unusually rich in such examples, and a brief record of the harvest reaped by these 'husbandmen of humanity,' with some notice of the means employed and of the men themselves, claims an appropriate niche in a journal from which the due commemoration of medical merit has at no time been withheld. Dr. Daniel Jerome Macgowan, whose parents emigrated from Ulster to North America shortly after the War of Independence, and who was born in Massachusetts in 1815, was for fifty years a medical worker in the field marked out in China by the Southern Baptist Mission. In the course of his life-long exertions he did much to bring the Chinese world into more sympathetic *rapprochement* with that of the West, and in the course of the discharge of the duties connected with his special occupation he was enabled to obtain a profound knowledge of the institutions, the character, the customs and the history of the strangely gifted and perversely governed people among whom his lot was cast. His researches found frequent expression in periodical and permanent publications, and these so impressed his British fellow-workers with their thoroughness and practical usefulness that our Foreign Office gave him a responsible post at Wenchow, whence he continued till within a few months of his death to enlarge the stores of knowledge, scientific and historical, which he had already amassed. An expedition which was undertaken to North China and the Great Wall in his seventy-ninth year proved to be beyond his strength, and on his return he was so enfeebled that he passed away peacefully on July 21st. Not only China, but Siberia and Japan, were included in his explorations; whilst his papers, embodying the scientific result of these efforts, will long be remembered as being honorable alike to the cause in which he compiled them and to the branch of the profession to which he belonged. A worthy successor in his footsteps, Mr. William Pirie, of Arbroath, entered on the same career two years ago, and he was even thus early acquiring an exemplary reputation for ability, energy, and self-sacrifice, when, as an intimation which has lately been received by the Church of Scotland Foreign Mission Committee tells us, he succumbed at Tchang amidst the deep regrets of the people among whom he worked and the friends who had watched his success."

Theobromine in Dropsy (*Le Progrès Médical*, August 5, 1893).—At the sitting of the Academy of Medicine, on August 1st, at Paris, M. Germain Sée reported seven observations on cases of dropsy healed by this drug with perfect success. It is an active diuretic, and is given in pills or cachets in doses of five to seven grains. Four doses the first day, six the second, eight the third, and ten the fourth. It should be given alone, and its effect maintained by the use of digitaline when its use is discontinued. Whatever may be the form of the cardiac lesion, it will be found to be efficient *quoad* the dropsy.

Treatment of Tuberculous Peritonitis.—Nolen (*Berlin klin. Woch.*, August 21, 1893) describes a new method. He would attribute any good results obtained by laparotomy to (1) the circulatory changes produced by the evacuation of fluid, and (2) the contact of air. He does not think that light has any effect. The author has accordingly practised tapping, with subsequent insufflation of air, after satisfying himself that there was no danger in this procedure. This treatment was tried in three cases, in two of which the results were very good. In the other advanced case (combined with intestinal tuberculosis) the ascites did not reappear, but the patient died eight weeks later. An apparatus is described by which air forced through sterilized cotton-wool, and then

through a flask containing sterilized water, is injected into the abdominal cavity after the fluid has been withdrawn. The apparatus is, of course, sterilized. The insufflation causes no pain, and does not give rise to any unpleasant result.

Ethyl Iodide is a drug which is periodically brought to the attention of the profession, but is not used largely, perhaps because of its volatility and expense. Dr. S. S. Cohen (*Medical News*) says of it: "In any case in which the local effect of iodine upon the air-passages is desired, or in which it is necessary to get a constitutional iodine effect, without resort to the stomach, the inhalation of ethyl iodide offers a convenient and effective means of accomplishing the purpose. It is thus of use in syphilis, and especially in cases of syphilitic inflammation or ulceration of the nose, mouth, and throat. It is of great benefit in tuberculosis of the larynx, and in pulmonary tuberculosis, at any stage of the disease, but especially when local stimulation and disinfection are desired. In subacute and chronic nasal catarrh, in some cases of hay fever, in subacute laryngitis and subacute bronchitis, and in chronic laryngitis and chronic bronchitis, when a sedative, sorbefacient, and disinfecting agent is desired, inhalation of a mixture of equal parts of terebene and ethyl iodide gives most satisfactory results. Ethyl iodide is extremely useful in ozæna and in fetid bronchorrhœa. It has been employed with apparent benefit in asthma, and in acute croupous pneumonia and acute broncho-pneumonia of various types. In one case of whooping-cough in an adult, it was apparently of service. It may be introduced into the Eustachian tubes and middle ear by means of a Politzer bag and catheter. To get the full benefit of the drug it must be used frequently and persistently. Thus, in cases of pulmonary tuberculosis, I have had patients keep up the daily inhalation for two, three, or more years. While in cases of active disease the inhalations are sometimes practised so often as every half-hour, in convalescent cases, or in cases of tuberculosis not showing active progress of lesions, the intervals are proportionately lengthened. Two hours constitute the average interval. Three times daily are sufficient in some cases. Some patients can inhale the vapor of ethyl iodide for ten or fifteen minutes without experiencing unpleasant effects. Others feel slight vertigo after inhaling for a minute or two. Ordinarily, I tell the patient to inhale for five minutes, unless vertigo is produced.

Alleged Intra-uterine Poisoning.—At a house in the neighborhood of Londonderry some tartar emetic was one day supplied by a chemist in mistake for tartaric acid, and used to make a summer drink. Of this, on August 8th, some twelve people partook, and all were more or less ill after it; among them was a woman far advanced in pregnancy. She vomited and felt cold about half an hour after taking the drink, and was obliged to go to bed, but the next day was practically well again. On August 21st, thirteen days afterward, she gave birth to a male child at the full term; the child seemed well and strong, and vomited once on the second day. It died on the evening of August 26th, aged five days, from convulsions. It was well until the preceding midnight, when it awoke and had stiffness of its jaw, and after that it had diarrhœa, vomiting, and convulsions up to the time of its death. An inquest was ordered, and the body was exhumed six days later and the viscera submitted to Dr. Leebody, who found traces of antimony in the liver and kidneys, amounting in all to one-fifth of a grain, but none elsewhere; he considered that the presence of the antimony was due to intra-uterine absorption, and declined to express an opinion one way or the other as to its being the cause of death. Dr. Steele, the dispensary doctor, who saw the child *in articulo mortis*, and made the necropsy, was convinced that death was due to antimonial poisoning, and the jury took his view and gave a verdict to that effect. In view of the fact that the woman was practically well for twelve days after taking the poison, before her confinement, and that the infant showed no symptoms of antimonial poisoning for the first four days of its life, it is not at all certain, the *British Medical Journal* says, that its death had anything to do with the tartar emetic, although the discovery of a minute quantity in the liver and kidneys is quite consistent with its having been absorbed *in utero*, as the time required for the complete elimination is known to be considerable. The case is, however, of considerable medico-legal importance, even though it be not regarded as an instance of antimonial poisoning.

The Antirheumatic Ring.—A writer in *Science Siftings* says that two thousand years ago the Greeks believed that there was virtue in finger rings as against rheumatism. Galen, in the second century, gave heed to some of the popular fancies of that day, and recommended a ring of jasper with an intaglio of a male figure wearing about his neck a bunch of herbs. Marcellus, in the time of Marcus Aurelius, prescribed a ring of pure gold, with certain Greek letters inscribed thereon, to be worn for pain in the side; the circlet was directed to be worn on the side opposite to the pain. The decrease of the moon was propitious to the plan of cure. "And these rings," says the writer, "had quite as much medical value as those that are now being sold for the relief of rheumatism."

The Feeding of Infants.—Hauser (*Berl. klin. Woch.*, August 14, 1893) describes a new method. He first refers to the well-known objections to a wet-nurse, and the difficulties in artificial feeding. The author has used, in Henoch's clinic and elsewhere, a preparation introduced by Reith, in which, after the smaller quantities of fat and sugar in cow's milk have been corrected by the addition of cream and milk sugar, egg albumin, heated above 130° C., is made to supply the deficiency in albumin. The preparation has the same composition as woman's milk, and is called albumin milk ("Eiweissmilch"), but would be more correctly named albumose milk. The difference between this and ordinary milk, when subjected to artificial digestion, is obvious. If feeding with cow's milk properly prepared and sterilized does not suit, the author uses this preparation. Medicinal agents are not employed, and washing out the stomach is rarely necessary. There are two classes of cases, (1) those in which cow's milk properly prepared seems to suit, and yet the infants do not thrive, and (2) those with dyspepsia, etc. Some sixty infants were treated with this preparation, and the author has now used it for one year and a half. The infants take it well, vomiting ceases even in those in whom other preparations have failed, and the weight increases. It is given in small quantities, and cold in bad cases. The stools become healthy and regular, but they may be offensive, owing to the sulphur in the albumoses. Failure is rare. This preparation is also useful in acute illnesses, in rickets, and some other diseases of children. Infants with whom mother's milk does not agree take it well. Older infants also thrive on it. Cow's milk may be added to it until pure milk feeding is arrived at.

The Human Body in Pharmacy.—Human fat passed for an excellent remedy against rheumatism, and the executioners most often turned criminal skulls over to the apothecary. Listen to the words of the illustrious Pierre Pomet: "We sell human axungia that we make, and which is derived from various sources. But, as we know, at Paris it is only sold to those that have need of it, and but little is given out; nevertheless, those who buy it have it prepared with aromatic herbs, which is much better than the kind coming from the public executioners." Human oils, the salty extracts of the blood and saliva, hair, toe-nails, urine, and human excrement have also been used in medicine extensively. Moïse Charras, in his "Royal Pharmacopœia," shows how to obtain these agents, and adds: "Man's dung, to which some have given the name of *occidental civet*, on account of its aroma, when dried in the sun changes its bad odor and

has many medicinal virtues. Distilled in a retort, we obtain an oil that is particularly recommended for the cure of erysipelas and other skin diseases." Charras likewise taught his pupils how to distil the after-births of women, an admirable remedy that Lemery recommended without reserve. "It is preferable," wrote Charras, "to take that which comes after a boy is born. This after-birth must be chosen from a young, vigorous, and healthy woman; she should likewise be beautiful. This after-birth, applied to one's face, will remove moles. Dried and powdered, it is a remedy against epilepsy; it likewise hastens labor. The dose is from one-half to two scruples." Remedies of this kind were common, and one often used was the essence of the spirit of urine. "The extract of urine drawn from young persons and taken with wine; it cures apoplexy, epilepsy, convulsions, etc.; mixed with balsam it is a sovereign remedy against hysteria." Madame de Sévigné frequently used this medicine, and writing to her daughter, on June 13, 1685, she says: "My blues have led me to take eight drops of essence of urine, and, contrary to its usual manner of acting, I was prevented from sleeping. But I am happy to state the esteem in which I hold this remedy. I have not needed a dose since."—*Cincinnati Lancet and Clinic.*

The Origin of Circumcision.—*La Médicine moderne* states that at a recent session of the Paris Society of Anthropology the question of the origin of circumcision was discussed. M. Letourneau recalled the custom of the Egyptians of practising phallotomy on the vanquished. This custom still prevails in our day among the Abyssinians. Every warrior who has killed an enemy, says James Bruce, presents to the chief a bloody prepuce. The ceremony being concluded, each warrior gets back his bloody trophy, and, taking it home with him, prepares it in the same fashion the Indians employ for scalps. This custom existed among the Hebrews, and to become the son-in-law of Saul, David had to bring in the foreskins of a hundred Philistines. Ritual circumcision is thus derived, and was an act of homage to God. The usage of offering portions of the body to the gods has been and is yet very wide-spread. It is a symbol of a complete sacrifice that has become partial by the lessening rigor of morals. It is thus that blood or the fingers were offered, or the sacrifice of their hair, by the early Christians.

Ipecacuanha in Hæmatemesis.—Dr. C. Burland writes to the *Lancet:* "The use of ipecacuanha in dysentery, both acute and chronic, and in various kinds of hemorrhage occurring in other parts than the bowel, such as the lungs and uterus, has been discussed in all the modern text-books on Materia Medica, but the treatment of hæmatesis by the drug is not insisted on or mentioned. The treatment which I found to be remarkably successful in the following cases has probably not been attempted, from fear that the emetic action of ipecacuanha might seriously increase the discharge of blood. It has generally been customary to give some sedative to the stomach, such as opium, before administering the large doses which are given in cases of acute dysentery, and this has evidently been thought to be necessary to avoid or control the emetic action of ipecacuanha. In my own practice in the East, where I have treated cases of dysentery for some years, I have seldom found the previous use of sedatives to be necessary, though at times it has been imperative on account of the exhausted condition of the patient, and I have dreaded the possibility of any vomiting with accompanying syncope." Dr. Burland then reports three cases and adds these specific directions: "I have selected these three cases on account of their exceptional severity. I would emphasize the necessity of keeping the patient motionless, with the spine arched forward by means of hard pillows placed beneath the dorsal column. Nothing whatever should be given by the mouth except the ipecacuanha; this should be fresh, and a few drops of tincture of opium ought to be added to sufficient glycerine to mould a mass into bolus. Especial care should be taken that no fluid is given either by the mouth or the rectum for at least two hours after the administration of the drugs. The patient's strength should be supported by nutrient peptonized enemata, and stimulants should be taken in the same manner. Brandy given by the mouth is almost invariably rejected and keeps up the vomiting. I am persuaded that in ipecacuanha administered with the precautions I have named there exists a remedy of singular potency in the treatment of hæmatemesis." The drug was used in doses of one drachm.

Telegony.—This is a term, says *Nature*, which Professor Weismann has recently coined to designate a class of phenomena which have thus far been pretty generally accepted as of unquestionable occurrence in mammals, if not also in birds, viz., the alleged influence of a previous sire on the progeny of a subsequent one by the same mother. Students of physiology are familiar with the instance of a certain mare who was covered by a quagga, and whose subsequent offspring presented unquestionable quagga marks. Within the last twelve months another seemingly unmistakable case of telegony has occurred in the Zoölogical Gardens, the first foal being a hybrid between two species of ass, and the second by a male of the same species as the mother. Most breeders and fanciers are so persuaded of the truth of "telegony" as to deem a pedigree animal seriously deteriorated in value if she has been covered by an inferior male, and even Darwin thought "there could be no doubt" as to the fact of this influence of a previous sire being occasionally exhibited in mammals. Professor Weismann, however, challenges the facts, but Professor Romanes has vouchsafed a number of instances plus an explanation in support of the existing view. There is so much margin for mere coincidence in matters such as this that unless the influence can be shown to be tolerably constant one is at liberty to ascribe the occasional traces of the influence of a previous sire to mere accident. If real then, the influence ought to be taken into consideration in arranging for the second and subsequent marriages of widows. Fortunately, there is every reason to believe that, even if real, the influence is only exercised when the successive impregnations take place within a comparatively short time of each other.

Our Consul at Bagdad is a most worthy physician, and a man of exceptional intelligence and scientific attainments. From Bagdad there is shipped annually to the United States between five and ten million pounds of wool. According to our Government regulations this wool must be disinfected, a labor that requires some four hundred trips to the disinfecting station from the consulate, and an equivalent of two hundred or more hours of active labor in a temperature of 120° F., or higher. For this frightful drudgery, to keep us from being cholera-stricken, the entire salary or fees will be $100 or less. This we glean from a private letter from our colleague. It is outrageously shameful that such a thing should be allowed. Dr. Sundberg is in his own way doing a vast amount of medical missionary work in this wretched place, whither he has been driven by his scientific zeal. There is no salary attached to his consular office. Is it not possible to make the office a salaried one, or to do something to help a noble physician struggling under adversity and in want, in order that we may be healthy?—*Medical News.*

Phenyl Cocain is made by mixing equal parts of cocain and carbolic acid, then dissolving the mixture in oil. It is said to be an excellent analgenic.

The Toad in Therapeutics.—Dr. Lauder Brunton, in his recent address to the Pharmaceutical Society, mentioned that phrynin has an action resembling digitalis, and he also remarked: "It is quite possible that some of these days we may have an enterprising firm advertising essences of toad as being of superlative virtue for the cure of dropsy."

Tuberous Chorditis.—In the recently published supplement to "Wood's Reference Handbook of the Medical Sciences," a work by the way which reflects renewed credit on the editorial skill of its learned editor, Dr. Buck, there is an article by Dr. Clarence C. Rice on chorditis tuberosa. The article is one of especial interest, since it describes what may be considered one of the new diseases, or, at least, a disease of modern public life. Chorditis tuberosa was first described by Türck, in 1866, his description being based on four cases. Later authors, if we except Dr. Rice, have not added much to Türck's original description. Tuberous chorditis is a peculiar laryngeal disorder always associated with catarrhal inflammation of the larynx, and characterized by the formation of a small whitish nodule upon one or both of the vocal bands. It occurs almost entirely in public speakers, actors, and singers. A celebrated *diva* suggested the lay view of the pathology of the affection when its laryngoscopic appearance had been described to her, by saying: "Why, I should say I had corns on my vocal bands." The observation was hardly correct, since the corn is purely epiblastic, while, in the tubercle, there is also a connective tissue hyperplasia. The affection is caused by excessive use of the voice, and particularly by bad methods of singing. It seems to occur oftenest in women and among sopranos. Among Dr. Rice's eight cases, six were women and were soprano singers. The nodule is small, situated near the middle of the chord, and is attached near its edge. There is always some congestion of the parts, and this may render its presence difficult to detect, except with a strong illumination. A person who has one nodule is very liable in time to have a second developed symmetrically upon the other chord.

The symptoms of tuberous chorditis are hoarseness and impairment in vocalization. The singer finds it difficult to produce clear notes, and unusually severe efforts have to be made, with the result of increasing the congestion and catarrh. The treatment consists in enforcing rest, and in correcting faulty methods of singing or speaking. Attention must be paid to the general condition of the nose and throat. Finally the nodule must be removed if possible by a guillotine knife, or caustic.

Strychnine and Picrotoxin.—Keener recommends the treatment of alcoholism by subcutaneous injections of the following solution:

		Grammes.
Nitrate of strychnine	gr. ij	(0.12).
Picrotoxin	gr. j.	(0.06).
Boiling water	ʒ j.	(30.00).

In the beginning about ten drops are injected, and the dose is increased by two drops at each injection, until the time when a slight dizziness or a constriction of the throat is felt by the patient after the injection; this usually occurs after an injection of from sixteen to twenty drops. The dose is then to be diminished until the cessation of the above-mentioned symptoms; the dose thus reached being continued until symptoms of intoxication again occur, which is generally the case after from seven to ten days. The dose is then very gradually diminished until it only consists of several drops, after which the subcutaneous injections are to be entirely omitted. The following solution is also to be taken internally:

		Grammes.
Bichloride of mercury	gr. i–ij.	(0.06–0.12).
Fluid extract of kola	ʒ j.	(4.00).
Fluid extract of cactus grandiflorus	ʒ j.	(30.00).
Fluid extract of arnica	ʒ iiss.	(10.00).
Tincture of aloes	ʒ ij.	(8.00).
Tincture of India hemp	ʒ ss.	(15.00).
Distilled water, sufficient quantity to make.	ʒ iv.	(120.00).

To be taken in teaspoonful doses every two hours during the day. This is to be continued during the entire period of the injections and for several days after their cessation, after which a tonic of iron, quinine, and strychnine (in any form, perhaps combined with iodide of potassium) is to be taken for one month. Attention must be directed to having the patient's bowels move regularly, and to the fact that a sufficient quantity of urine should be secreted.—*St. Louis Medical and Surgical Journal*, June, 1893.

Figure-heads in the Programmes of Medical Congresses.—Complaints are multiplying of the reprehensible practice of announcing as contributors to a proposed medical congress all or many of the great names that it would be desirable to have read papers, regardless of the fact that such persons have not proposed to do so, have not accepted invitations, or have even positively declined to contribute. It may show "enterprise," but "enterprise" is often a euphemism for very contemptible practices.—*Medical News.*

Bagdad Pharmacy.—A correspondent of the *Pacific Medical Journal* gives the following account of the attractive pharmacy of Bagdad: The practice of medicine is in a degraded state, and patients are constantly bargaining with the physician for a cure, and refuse to pay for advice pure and simple or for an examination, no matter how much skill or time it may involve. When a wealthy person is taken ill all the doctors and magicians in the city are sent for an hour or two apart, and without each other's knowledge, and their advice is followed or not, as it suits the fancy of the women neighbors, who always try to pump the doctor by fair means and foul. If a prescription is sent to the drug-store it will probably be put up in an old, unwashed cod liver-oil bottle that has lain perhaps for months in some dirty corner, and then an old rag and some paper is made to do service as cork. This is not overdrawn. Sometimes the prescription may be put up in a cup without any cover at all. The percentage-on-prescription system has here been developed and refined as nowhere else. There are benevolent societies whose secretary receives as salary a certain amount on every prescription he has to settle for, and then he and the doctor agree that a new prescription shall be written for every dose!

The Conduct of Medical Life.—In the course of a recent lecture Dr. Weir Mitchell says: "Character is the true and sure object of a rational existence. Back of this character must be a creed. The practice of medicine is a profession, not merely a business. He who looks upon it commercially, and only thus, is apt to fail of even the mere financial form of success, because it is the peculiarity of our mode of earning a livelihood that it is not and cannot be regarded as a mere business. The more we study the lives of exceptionally successful physicians in all ages, the more clearly will we come to see that the brilliant triumphs have fallen most often to those who had the highest ideals as to what they were dutifully bound to give, rather than what they were in return to get. I am fond of saying that in our work we sell what neither we who sell nor those who buy can weigh or measure. We have no public to which we bend with abject submission, as does the lower newspaper man, most timid of the reptilea; no judge or jury listens to us; no press or public looks on to applaud or condemn. What we do, neither patient nor his friends can fully understand. One silent auditor makes up our moral accounts. That we live and are to live very largely a life of isolated self-judgment, that neither scale nor measure approves the amount and integrity of what we sell—this, I think, should make us doubly careful. I want you to go hence with unattainable ideas of what you mean to make your lives; the higher the better. At all events, have and hold distinct conceptions as to the qualities which make men great in the higher manhood of medicine, and acquire them now. The world may make strange havoc with your views when, as years go on, you are to be guided by them in the every-day work of life. But he is to be pitied who, when young, having no ideals of duty, waits for opportunity to generate a code of conduct."

RARE FORMS OF GOUT AND RHEUMATISM.[1]

BY SIR JAMES GRANT, M.D., K.C.M.G.,

OTTAWA, CANADA.

MR. PRESIDENT AND GENTLEMEN: This I consider "a red letter day" in my professional life's work, and more particularly from the very fact of having received so generous an invitation, through the secretary of your Association, to read a paper on this auspicious occasion. We Canadians, as a whole, delight in noting the advance of our American neighbors, in almost every line of thought in medical and surgical science. The assembled wisdom of this Association from the State of New York, almost a kingdom in itself, is only an index to the intellectual power to-day at work in almost every State of your prosperous republic. How gratifying it must be to con over such names as Rush, Mott, McDowell, Sims, Gross, Pancoast, Flint, Sayer, Thomas, Emmet, Da Costa, Bowditch, Godell, Pepper, Weir-Mitchell, Bull, McBurney, and a host of others equally great, but too numerous to mention, who by their skill and ability have added lustre to the name of America. To-day I propose offering some observations on rare forms of gout and rheumatism, conditions not by any means frequent, as to their occurrence.

CASE I. *Pneumonic Gout.*—The following brief notes are of a pneumonic form of gout, associated with slight hepatic complication. H. V——, seventy-eight years of age; stout habit of body, not plethoric, but generally vigorous, and accustomed to long hours of arduous official duty; cannot trace gout to his ancestors and always lived well and liberally. February 10, 1893, suddenly seized with acute pain in the right side of chest, opposite the middle lobe of lung, with general malaise and rather severe cough; no excessive flushes in the cheeks; the breathing was somewhat hurried, about thirty per minute; temperature, 101½° to 103° F., and the pulse ranged from 100 to 114. The cough after the first day was associated with the expectoration of a thick, tenacious mucus, and rusty-colored, not uniform, however, in its character, but somewhat patchy as to the distribution of the blood through the tough sputum. The left side moved more freely during the respiratory process than the right, and over and about the seat of pain in right side there was an evident area of dulness on percussion, and yet the breath-sounds were heard with a degree of almost unexpected clearness, with an occasional slight mucous râle. The posterior aspect of the right lung held its ground, kept moderately clear, and in fact the pulmonic trouble was chiefly confined to the lateral and anterior aspect, middle lobe, right lung. Throughout the sputa presented an unusually tenacious character, and up to February 21st exhibited a patchy, rusty, and most peculiar appearance, after which date it became clear, but retained the sticky, glutinous peculiarity up to February 27th, when it subsided. During the entire illness the pain in the side was not of the usual pleuritic type, but more of the burning, throbbing, aching, and piercing pain, and out of all proportion to the ordinary defined pulmonic condition. From his well-known gouty diathesis I was led to believe the attack was really one gouty in character, and informed the friends that metastasis of the lung condition to the feet was not unlikely. On February 22d both feet became very painful and swollen, a condition of system (as to his feet) he had experienced several times during the past ten years. Almost immediately the lung improved in every particular, which quite settled the point as to the gouty character of this attack in the lung tissue as a primary development. Throughout the usual course of treatment was adopted, with the free use of elixir, salicylate of lithia, and lithia water as well. During the entire attack I saw no special indications of hepatic trouble, beyond a degree of uneasiness about the liver generally. Four years ago he had a well-defined attack of jaundice, unattended by anatomical lesion to account for its development; it was of short duration and passed off quickly.

CASE II. *Perityphlitic Gout.*—The same individual whose case I have just cited, was the subject of the following data: September 10, 1892, aged seventy-seven. Almost up to the present attack had been enjoying apparently good health; retired to bed this same evening, and in the middle of the night was suddenly seized with a severe pain in and about the region of the appendix vermiformis, attended with a sensation of throbbing, together with a degree of tension in this particular region which radiated more or less over the entire abdominal walls; considerable heat of skin, with a degree of restlessness, general febrile disturbance, and a sense of uneasiness about the stomach, with occasional vomiting. Temperature, 102° F.; pulse, 116, full and regular. The pain and sensibility of the abdominal wall was chiefly over the ileo-cæcal region. The bowels were constipated and the tongue moderately coated with a moist white fur, pointing to evident gastric derangement for a few days. Knowing the gouty history of this patient for some years, although not of an hereditary type, I suspected from the character of the pain, boring and gnawing, such as I had observed more than once in his feet, that it might prove a case of gout, of which there were well-defined results, such as tissue-thickening about the tarsus and heels of both feet, owing to the deposition of gouty material during past years. The fingers in both hands showed also evidences of disturbed chemistry in the system, resulting in gouty thickening in and about various joints. The bowels, though at once relieved by an enema, still continued painful. Linseed poultices were freely applied, sprinkled with chloroform liniment, and tablets of sulphate of morphia freely administered, to relieve the intense suffering, which was so acute as to almost prohibit the most moderate bed-clothing. Salicylate of lithia and lithia water were freely given so soon as admissible, and the bowels were frequently washed out with warm water, which almost played the part of an internal poultice. The pulse and temperature continued high for fully five days, when both gradually lessened in intensity, and about the sixth day pain was complained of in both feet, particularly about the toes, but not by any means as severe as in the marked metastasis after the attack of pneumonic gout.

At this date there was a marked amelioration in the entire character of the symptoms, the abdomen became more flaccid and much less painful on pressure, and the decidedly cakey area, in the ileo-cæcal region, gradually parted with its suspicious indications. McBurney's appendix point was for days an interesting and instructive lookout, until rendered less attractive by the evident outcome of metastatic gouty action. Undoubtedly there was well-marked and circumscribed induration in the ileo-cæcal area. The precise condition or character of this induration was difficult to define, and yet the rapid

[1] Read at the meeting of the New York State Medical Association, October 11, 1893.

change consequent on metastatic action pointed to gouty deposition in or about the region of the appendix, so peculiar and transitory in its manifestations. At the end of three weeks an excellent recovery was made, and since that date there has been no recurrence of intestinal trouble.

Case III. *Rheumatic Perityphlitis.*—Miss T——, twelve years of age, vigorous and robust habit of body, conformation regular, and organs, as a whole, normal prior to present attack. Of a highly nervous temperament, but usually enjoyed excellent health and spirits. June 1, 1893, complained of pain and sense of uneasiness in her feet, with a general feeling of systemic irritability. June 3d, was suddenly seized with severe pain in the bowels, but more particularly in and about the ileo-cæcal region, where tenderness on pressure was most marked. Fully two days prior to June 1st, a sense of heat and feverishness was experienced, and prior to being under my charge. Temperature, 102½° F.; and pulse, 120. The bowels were at once washed out by a warm water enema, which afforded much relief. Hot linseed poultices applied, and placed on milk diet and an aconite mixture. From June 2d to 8th the pain experienced over the bowels was very considerable, and the tenderness so severe that coughing or stretching of the legs increased the pain in a most marked manner. Turpentine enemata also afforded considerable relief. June 4th there was a decided hardness on moderate pressure over the ileo-cæcal region, which gave one the impression that some tissue change had taken place; and the fact that rigidity in the abdominal walls was more marked on the affected side than on the other, led me to view the condition with a degree of suspicion, although the actual position of hardness was a little lower down than McBurney's point. For fully three days the temperature was over 102° F., on which account suppuration would not be an unlikely result. June 7th, the right shoulder, elbow, and wrist joints exhibited well-defined symptoms of acute articular rheumatism, these parts being painful on pressure, swollen, and moved with difficulty. Just in proportion as these almost outside rheumatic conditions developed, the abdominal symptoms actually lessened in intensity, and on the 10th the entire features of the case evidenced a marked change for the better, no relapse being experienced whatever. The question very naturally arises, What was the attack, and how developed? True, the recognition of appendicitis is not all that is needed.

In this case, almost from the first, there was a localized pain associated with tenderness over the region of the right iliac fossa and ascending colon, with well-defined swelling, and for days the pain was so severe that it was increased at once by coughing or deep inspiration, and the almost constant desire was to elevate both knees to relieve suffering. For days also there was entire inability to take nourishment, owing to attacks of vomitting. The bowels were frequently injected with warm linseed tea, which afforded a degree of nourishment as well as clearing the contents of the canal. In this case I concluded there was lodgement of undigested material in the cæcum, and most likely induced by inability to assimilate the food, owing to deflected nerve-power from over-mental strain, as is frequently the case in our schools and universities at the present day. In the ordinary avocations of life we can trace the operation of like results interfering seriously with the very principles of sanguinification and blood change.

The next question is, How is rheumatism associated with perityphlitis? True, the essential cause of rheumatism is still a doubted point. Errors in diet as an etiological factor, have much to do with the production of both gout and rheumatism, and such strengthen the metabolic theory, that rheumatism depends on a morbific material produced within the system, the result of defective processes of assimilation. True, Prout, Latham, Richardson, Mitchell, and Dr. William H. Porter, of New York, have thrown much light on the subject of rheumatism, and certainly the present case points to rheumatic complication as the outcome of defective assimilation, an important factor in its production. Thus the chemical laboratory of the human system becomes disturbed, resulting in false products, enabling us to establish a connecting link between even perityphlitis and rheumatism. In the structure of the intestinal walls there is undoubtedly a large amount of fibrous tissue, just as in the fascia and tendons of the joints, and it is reasonable to suppose that these structures should be influenced in the same manner; and assuming that the case under consideration was even quasi-rheumatic in its character, it affords one more illustration as to the importance of giving due consideration to the line of action embraced, in medical or surgical treatment, under like circumstances.

In a recent paper by A. Haig, M.A., M.D., Metropolitan Hospital, London, on gout of the intestines, he states, "that his chemical and experimental experience has led him to believe that a very large number of cases of colic, enteralgia, and enteritis, and cases which are clinically indistinguishable from typhlitis, are neither more nor less than a gout of the walls of the intestinal tube, or a rheumatism," as has just been defined. In Canada, as a whole, gout is almost an unknown quantity, except in occasional cases of an hereditary type. Our people, in the midst of life's pursuits, live in a moderate way, which contributes greatly to the promotion of health. On the other hand, rheumatism is of frequent occurrence. The coldness of our winter climate, the occasional absence of flannel, and excessive exposure, contribute to develop rheumatism. After noting the life-history of many thousands of our "lumbermen," I have been amazed at the few attacked by rheumatism. Bread, pork, and strong tea constitute their chief articles of diet, and the general experience is, that the tea enables them to digest the pork with remarkable comfort; and certainly, after a hard winter's work, they return home well nourished and healthy in every particular.

These facts point to simplicity as to diet. Our progenitors frequently attained the age of "threescore and ten," nourished by grain ground between two stones. As a rule, the people of the present generation live too fast, resulting in mental strain and the absence of simplicity. With greater attention to diet, simple in its character, in conformity with the normal functions of the alimentary canal, and the avoidance of alcoholic beverages as a whole, I feel confident perityphlitic and appendix troubles, even unconnected with gout and rheumatism, would become less troublesome factors in the line of disease. To avert various irregularities in the alimentary canal, which, if neglected, will undoubtedly lead to trouble in time, is as important as subsequent treatment, when the stage is passed in which the efforts of nature are powerless to afford relief. What active agent in the system is more frequently tampered with than gastric juice, which requires a normal temperature to perform its part in the economy? Ice-water at the commencement, and ice-cream at the end of a meal, may be fashionable, but certainly not life-preserving. Unassimilated food makes its way to parts not designed by nature, to transform and absorb. As the result, how frequently, on percussion, we find extensive portions of bowel ballooned by abnormal efforts to accomplish the digestive process. Such conditions result from irregularities in living. No portion of the alimentary canal is more liable to diseased manifestations than in and about the appendix, which is a species of Loop Line to the digestive tract.

Insurance associations cannot note too carefully the probabilities of life in this connection. There is still much to be accomplished, and let our medical education be so directed as to bring about simplicity in living, as near as possible, to the normal functions of our organs, and our generation will be greatly benefited.

The Physician gets on without learning if he has address; if he has learning without address, let him be a bishop.

ALBUMINURIA WITHOUT MANIFEST ORGANIC RENAL LESION.[1]

By WALDRON B. VANDERPOEL, M.D.,
NEW YORK.

The topic I propose to present for your consideration will appeal strongly to that individual for whose benefit so much medical literature has of late years been written, the general practitioner, as on his correct diagnosis and proper treatment will here, in an unusual degree, depend whether the patient will enjoy many years of full or comparative health or the reverse; to the examiner for life insurance it presents one of his most difficult problems, and on his clear reading of the case will depend large financial interests as well as his professional reputation, and the popular estimate of the exactness of medical science.

Clinicians have long been familiar with a class of cases in which the only abnormal symptom has been the passage, constantly, or from time to time, of small or even large amounts of albumin in the urine, and this extending over a period of months or years. To these cases have been applied the names of functional, physiological, paroxysmal, intermittent, cyclic, or chronic albuminuria by different writers, according to the standpoint from which they viewed them.

To Dr. Bright, of England, we owe our first clear idea of the clinical importance of albuminuria, as portrayed in his "Reports of Medical Cases," 1827 and 1831, and the subsequent elaboration of the same is largely due to the investigations of Christison, Rayer, Frerichs, Traube, and others. For a long time it was considered sufficient to ascertain the presence of proteid matter to pronounce the case a renal affection, in all probability a nephritis, and the worst prognosis was accordingly drawn. It is now well known that we may find in the urine several other proteid bodies besides albumin, each bearing its own significance, and the presence of many depending on causes widely remote from the kidneys. In point of time we find that Sir Robert Christison,[2] in 1839, pointed out that certain articles of diet sometimes caused a temporary albuminuria. Jaccoud,[3] in 1864, laid down the proposition that there are cases of persistent albuminuria in persons in otherwise good health. Moxon,[4] in 1878, published a paper on "Chronic Intermittent Albuminuria." Professor George Johnson,[5] of England, in 1879, announced his observations on the occurrence of albumin in the urine of persons otherwise apparently healthy. Later we have many writers, notably Pavy,[6] who designated these cases as "cyclic" or "physiological;" Grainger Stewart, Sir William Roberts, Professor Fraser, Mahomed, Finlayson, Saundby, Tyson, Pye-Smith, Goodhart, Ralfe, and others in England; Senator, Jaksch, Virchow, and others in Germany; Capitan, Chateaubourg, C. Finot, Dieulafoy, and others in France; Millard, W. H. Porter, Munn, Washburn, W. B. Davis, Da Costa, and others in our own country.

The opinions held as to the frequency of the occurrence of albuminuria in otherwise healthy persons differ widely. Some, notably Posner[7] and Senator,[8] claim that their observations warrant the belief that repeated examinations, over long periods and at different hours of the day, will eventually show albumin in every healthy person, and that we may regard an albuminuria as physiological, just as we recognize a physiological glycosuria, oxaluria, or indicanuria. Washburn[9] reports he has confirmed these results with picric acid and other delicate tests in fifty persons, finding albumin in all. Sir William Roberts[1] says that concentrated urines from persons of undoubted health are comparatively rarely free from traces of albumin detectable by direct testing. In ordinary processes of testing these traces are naturally overlooked, but certainly exist very frequently, and their existence shows how nearly on the verge of a sensible albuminuria healthy persons are. Others report varying percentages, viz.: Chateaubourg,[2] 592 in 701 persons examined = 84 per cent.; Capitan,[2] 44 in 98 soldiers = 44.9 per cent.; Van Noorden, 3 to 35 per cent. in German soldiers under differing conditions of rest or fatigue; Grainger Stewart,[3] 31 per cent. in 407 examined, and therefrom formulates the statement that it will be found in one in three of the male population if examined during the active period of the forenoon, an hour or two after breakfast; before breakfast the proportion would be considerably smaller; Edes, 10 to 20 per cent.; Munn,[4] 24 in 220 examined = 10.9 per cent.; Washburn, of Milwaukee, 5.91 per cent. in 338 examined; Shepherd, 2 per cent. in 35,471 examined. These differences are difficult to reconcile; they may, in part, be due to varying conditions of seasons, pursuits, and habits of the subjects examined, also thoroughness of the observers, etc.; still we may have to conclude that they have given more attention to this subject and been more systematic in their examinations in foreign countries.

In considering the subject of albuminuria, we must recognize two primary forms, viz., one whose origin is entirely extrinsic or remote from the kidneys, often called false albuminuria, and the other, intrinsic or true, depending on changes in the renal circulation or structure; but followed in their later history it becomes difficult, if not impossible, to draw any sharp dividing line in these cases, as those which at first were purely extrinsic by their persistency and secondary effects, frequently become true or intrinsic, and a knowledge of their prime nature only to be attained from a study of the chemical nature of the proteid bodies presented in the urine.

Clinically, we may group these albuminurias under a threefold heading, under which may be brought all the varied cases reported by different writers, viz.: I. Simple albuminuria without preceding or accompanying symptoms, persistent or intermittent, and giving no indication from urinalysis of organic renal lesion. II. Uric acid or oxaluric form. III. Neurotic form.

I. **Simple Albuminuria.**—To this class can be assigned all those cases which continue for years without any apparent deviation from the normal in health, presenting no preceding or accompanying symptoms of disturbance in the digestive, circulatory, or nervous functions, and would never have been discovered except accidentally, either in the routine examination of the urine by the family physician or by the insurance examiner on the subject's application for a policy in life insurance. These are the true functional or chronic albuminurias.

As causes we find prominent: 1, dietetic; 2, exposure to cold or cold bathing; 3, muscular activity; 4, mental strain or worry, prolonged brain activity.

1. *Dietetic.*—(*a.*) The mere ingestion of food markedly favors the appearance of albuminuria where the predisposition already exists. Grainger Stewart reports, as to the effect of the taking of food, that he examined the urine of 32 soldiers before breakfast and after, finding albumin in 5 in the former and in 13 in the latter, and in a total of 160 examinations of soldiers, old men, and children, in twenty per cent. before breakfast, thirty-five per cent. after. Ch. Finot[6] reports albumin in 5.5 per cent. before breakfast, and in 11.6 per cent. at midday. Capitan and Chateaubourg confirm these results. Pavy

[5] La Semaine Médicale, February 17, 1892.

states that albumin is frequently absent from the early morning urine and appears later in the day after the first meal has been taken, and then gradually falls off in amount to a mere trace at bed-time. His habit is to require four specimens of urine for examinations, one at the rising hour, one at noon, one at 6 P.M., and one at bed-time.

(*b.*) Some persons manifest an idiosyncrasy toward certain articles of food, developing albuminuria after their ingestion. These are especially eggs, cheese, buckwheat cakes, pastry, meat, etc. The peculiarity is most marked where the amounts consumed are large. Stokvis [1] reports experiments in animals with egg-albumin, introduced by the stomach, rectum, and subcutaneously, resulting invariably in the appearance of egg-albumin in the urine. Injection of serum-albumin in an animal of the same species was negative, unless the quantity was sufficient to raise the blood-pressure considerably. The results from ingestion into the stomach of human beings have not been so uniform, some experimenters, as Drs. Lauder Brunton,[2] Dobradin, and Maguire failed to produce albuminuria by swallowing a number of raw eggs in rapid succession, while D'Arcy Power and Claude Bernard succeeded in so causing it. Grainger Stewart details a series of experiments from which he reaches the conclusion that, in general, the introduction of raw-egg albumin into the stomach induces albuminuria, always in small amount, and it is not egg albumin but serum-albumin; also that all albumin disappears from the urine when ordinary diet is resumed. The same results have been obtained in experiments with cheese and the other articles mentioned.

The explanations offered for these conditions are conflicting, and not in all cases clear. The form following the mere ingestion of food may at times be due to an already impaired or diseased gastric or intestinal function, resulting in an imperfect metabolism and the development of toxic products in the blood which cause direct renal irritation in their excretion, or again, under certain conditions, the renal circulation may be influenced, either reflexly through the nervous system, or directly by a plethoric condition of the blood, so as to allow of a transudation of albumin. In the form depending on idiosyncrasy toward albuminous foods, it was formerly held that egg-albumin was directly absorbed into the blood and discharged as such from the kidneys, this being rendered more plausible by arguments showing that the molecules of this form of albumin were smaller, hence more transfusible. Five explanations are now entertained by different writers: *a.* That there is a condition of overcharge of the blood with albumin and some of the excess escapes in the urine. *b.* That severe digestive disturbance is produced and uric acidæmia or oxaluria developed, bringing these cases under our second main classification. *c.* In accordance with the theory of Dr. Thomas Oliver,[3] of New Castle, that urea is mainly formed from the red blood-corpuscles, and most when the liver is at its highest activity during digestion, considering that the liver would very likely be unusually stimulated by the excessive amounts of nitrogenous matters presented to it, and hence the blood-corpuscles destroyed in larger numbers, we would have a corresponding excess of albumin liberated, and this not being at once transformed into urea, appears in its own form in the urine. Credit is due to Drs. Rolfe [4] and Noël Paton [5] for investigations upon which this theory is based. *d.* Animals in whom albuminuria had been artificially produced by the ingestion of large amounts of albuminous substances by Semmola, were killed, and the lesions of well developed glomerulo-nephritis were invariably found in their kidneys, undoubtedly due to the irritant effects of the egg-albumin. Hence we have in this case an actual organic lesion. Millard claims this to be true in a large percentage of these cases, and cites as proof a case reported by Christison, which eventually died of Bright's disease; also a patient reported by Germain Sée had all the symptoms of Bright's disease; and Claude Bernard, whose experiments we have quoted, himself died of Bright's disease, apparently. *e.* Increase of the salts of the blood, and also of urea; the latter we may expect after a meal such as we are considering, favor osmosis, and hence may induce exudation of albumin.

2. *Exposure to Cold or Cold Bathing.*—The existence of a form of albuminuria due to this cause was first described by Dr. George Johnson, of England, in 1879. Grainger Stewart gives as results from an examination of 21 boys, on rising, albumin in 4; after cold plunge bath, 5. There was an increase also in the amount of albumin in each. As causes we have mainly reflex nervous action on the renal circulation from peripheral irritation, and also increased excretory work thrown on the kidneys by the suspension of the perspiratory function of the skin.

Dr. Sewill describes a patient now living in his seventy-seventh year, who, twenty-six years ago, was markedly albuminuric. The causation was later assigned to undue indulgence in sea-bathing in cold weather. Family history good, and he had always been healthy. He was fleshy, indolent, and a large flesh eater, took alcohol in moderate amount. In the course of four or five illnesses during the past twenty years, albumin had been found, but his health was not seriously impaired, although he disregarded all dietetic regulations. Three years ago an ascites and abdominal abscess appeared, and his life was despaired of. He is now well and hearty, and scoffs at regimen, etc. Dr. Sewill cites this case as showing the difficulty presented to insurance examiners in determining proper risks.[1]

3. *Muscular Activity.*—We are made familiar with this cause for albuminuria by the observations of Grainger Stewart, of the urine of foot-ball players and soldiers after a long march. Weston, after his long walk in London, had both albumin and casts in his urine. Under the same category fall all states, conditions, or pursuits which involve any tax on the physical powers; thus we have cases occurring among blowers of wind instruments, after parturition, and finally a form depending wholly on posture. Pavy [2] instances a young collegian aged eighteen, a good athlete, who stood a civil service examination, but albumin being found in his urine, he was rejected. The case was cyclic, however, and he was afterward passed. He went to Oxford, and from there went up for a final physical examination before going out to India. Having meanwhile read up the literature of these cyclic cases, he remained in bed until just prior to his examination and was accepted, there being a temporary cessation of the albuminuria. The erect posture evidently acts in these cases as violent exercise does in the more robust. There exist wide differences in the reports of different observers. Chateaubourg gives 201 cases in 230 soldiers examined. Griswold,[3] in 24 examinations after three- to four mile walks and other vigorous exercise followed by cold baths, failed to find any albumin. Van Noorden reports 23 cases out of fifty-three samples of soldiers' urine after exercise, viz., forty-three per cent. Millard [4] explains these differences as due to faults in testing, and claims that all the conditions of muscular fatigue, riding, marching, etc., favor an increase of secretion of mucus from the lower urinary passages, and especially if there should exist slight irritation of the urethra, prostate, or bladder, the remains of an old gleet or cystitis. To differentiate between albumin and mucin is very difficult and requires very delicate and carefully applied tests, together with the systematic use of the microscope, by which accompanying conditions characteristic of mucinuria may be discovered. Under this heading appropriately fall cases attending upon manifestations of chorea and epilepsy, considered from a view of the muscular activity accompanying them,

although they are usually classed under the neurotic type and their causation considered as due entirely to nervous phenomena.

The kind of albumin found in this class of cases by different investigators has varied; Dr. Maguire reports a varying amount of paraglobulin, and draws a prognostic inference that, the greater its amount in proportion to that of serum albumin, the more favorable the case; Pavy finds alkali albumin sometimes instead of serum albumin. Dr. Oliver,[1] of Harrogate, reports a case of intermittent albuminuria in which peptones replaced albumin for a long time. Again, Grainger Stewart tells us sugar may replace or accompany albumin, and he deduces from this proof of the theory that faulty metabolism has also here much to do with the production of the condition. Other chemical changes mentioned by Stewart are excess of phosphates in addition to, or alternating with, albumin; urates may be very abundant and sometimes uric acid, but most common of all, oxalate of lime.

The explanation of these cases offered by Stewart is altered blood-pressure in the Malpighian tufts and renal blood vessels; he claims as confirming this the metabolic abnormalities just mentioned, as indicating like influences in the hepatic circulation, possibly. It has been found that increased arterial pressure does not favor albuminuria, but increased venous pressure and slowing of circulation do materially favor it; hence many of the mechanical cases, viz., pressure of abdominal tumors and the gravid uterus on the renal veins or ureters. Operating in like manner on the renal circulation was a case recently reported of intussusception[2] of the right ureter; also a case due to a retroverted[3] uterus, where correction of the faulty uterine position resulted in disappearance of the albumin.

The strain to which the kidneys are subject in eliminating the excess of excrementitious products resulting from muscular activity, forms another potent factor.

4. *Mental Strain or Worry, Prolonged Brain Activity, etc.*—Fürbringer records the case of a medical man who showed albumin only as a result of mental excitement, all the ordinary excitants of this condition failing to produce it. Altered blood-pressure in the renal vessels depending on direct nervous influence from the brain, will explain the origin of these cases. Here may be classed all cases due solely to reflex nervous influences, and as such we may possibly view the case of retroverted uterus just cited, if its effect can be considered due to pressure on nerve trunks.

II. **Uric Acid or Oxaluric Form.**—The characteristics of this class have been clearly portrayed by Da Costa.[4] As the name indicates, the distinguishing feature is the appearance in the urine of an excess of uric acid crystals or urates, amorphous or crystalline, or crystals of calcium oxalate. The actual quantity of urine passed remains normal, but the amount of solids is increased, and it is often spoken of as loaded or concentrated urine, specific gravity 1.022 to 1.028, or 1.036. Chlorides are normal or increased in amount, never diminished, as they are uniformly with contracted kidney. Phosphates and urea normal or increased. Casts, hyaline or epithelial, may or may not be present. Albumin usually small in amount and may vary with the time of day, being most in the early urine and possibly absent in the evening. In our testing we must again be careful to avoid error from mucin, which is liable to be abundant in these urines. The clinical significance of each ingredient varies, but they all indicate a defect in the assimilative functions, and especially so do uric acid and the urates, which in some cases are due to imperfect oxidation into urea, but for the most part trace their origin to imperfect hepatic functioning. This condition is predisposed to by (1) over-indulgence in a not sufficiently mixed diet, either nitrogenous or carbonaceous. In moderation carbonaceous food is easy of transformation, but in excess the hepatic function is overtaxed and its powers impaired for acting on the more arduous nitrogenous substances. Excess in nitrogenous diet will manifestly prove a still greater tax. (2) A possibly inherited condition called the uric acid oxlithemic diathesis. This is a sensitive or vulnerable condition of the liver and kidneys, in which they are more prone than ordinary to suspend their functions. This state many writers, notably W. H. Porter,[1] consider due to generations of abuse of those organs, and not correctly a diathesis. Regulation of diet will largely, if not entirely, cause its disappearance. Oxalate of lime bears the same clinical import; some vegetables contain an abundance of this substance, and may favor in their consumption an oxaluric condition, as do also nervous worry and strain.

The cause of albuminuria here is probably a purely mechanical one, depending on the irritation produced by the imperfectly formed metabolic products, and markedly so by the sharp crystals of lime oxalate or of uric acid. These crystals may lodge in the renal tubules by accretion, attain a moderate size, and cause a persistent albuminuria following after an intermittent one. Altered blood-pressure in the kidneys may be produced reflexly through irritation of the pneumogastric branches in their final distribution, and so contribute another cause; and again chemical changes may occur in the blood as still another cause.

No marked symptoms may attend these cases which would indicate any disturbance of the digestive, circulatory, or nervous functions, and they may continue for years undiscovered and never result in any organic kidney disease. More commonly we get a clear history of prolonged irregularities of diet followed by functional digestive disorders, manifested by uncertain appetite, flatulence, etc., and later nervous symptoms, viz., headache, sleeplessness, vertigo, etc.; and circulatory disturbances, viz., irregular pulse, usually feeble, but may exceptionally show increased tension and some rigidity. A symptom to which Da Costa draws marked attention is a slight rise in temperature, particularly in the afternoon, which he interprets as signifying increased renal activity, due to the excess of imperfectly formed excrementitious substances they are called upon to eliminate.

Under this category a number of the so-called dietetic albuminurias, primarily in part, and eventually wholly, fall, that is, where we have secondary digestive disturbances inaugurated and a true mal-assimilative albuminuria developed. Da Costa ranks here also the majority of the cases of this affection in boys, called by most writers the albuminuria of adolescence. Sir William Gull[2] speaks of this adolescent form as occurring in boys and young men about as often as spermatorrhœa.

Many writers consider they can trace in this class of cases the uric acid type, a true pre-Brightic stage, so called, which, if allowed to continue untreated, will eventually develop the rigid arteries, persistent high-tension pulse, and retinal changes of chronic nephritis, and contracted kidney. An interesting paper detailing cases illustrative of this condition, and tracing the sequence of events, was read by Dr. R. Van Santvoord[3] before the New York Academy of Medecine a short time ago, in which he shows that it is not unusual, where dyspeptic symptoms have continued more or less constantly over a long period of months or years, for organic changes to appear, manifested lastly in the circulatory system by continued high pulse-rate and tension indicative of commencing arterial sclerosis and cardiac hypertrophy, the cause possibly being ptomaïnes or other toxic substances, derived from defective metabolism, circulating in the blood.

III. **Neurotic Type.**—We have here cases following or accompanying manifestations of epilepsy, chorea, apoplexy, hysteria, influenza, exophthalmic goitre, and Stew-

art reports a case accompanying infantile paralysis, also one with multiple sclerosis, and again with the general paralysis of the insane. Puncture[1] of the floor of the fourth ventricle, near the location which causes glycosuria, Bernard showed some time ago, would produce albuminuria, and we have like effect from lesion of the cerebral peduncles, also from section or irritation of the spinal cord.

The explanation of these cases generally accepted is direct nervous influences acting from the brain or spinal cord through the splanchnic, cœliac, and renal nerve plexuses, by whose irritation the vessels of the kidneys are contracted and by their paralysis dilated; in the latter case the volume of the circulation, not the rate, is increased, and secretion correspondingly increased.

There remain a few forms of albuminuria which I have been unable to assign to any class enumerated, as their etiology is to me obscure; such are a form mentioned by Dr. Lambert[2] as attending extremes of temperature, another found largely in the newly born, and lastly, after anæsthesia in some cases.

Let us consider the prominent clinical features presented, and endeavor to ascertain the value and bearing of each upon our diagnosis, prognosis, and treatment. This is of unusual importance here, as a diagnosis can often be made only by exclusion, hence the import of each symptom must be carefully weighed.

1. *Pulse rate and Tension.*—In the simple non-organic forms the pulse is normal in rate and usually feeble. While these conditions remain the case may be considered purely functional and such have been accepted by insurance companies and proved good risks. When the pulse-rate and extension are both constantly increased, we may justly consider that we have to deal with a commencing cardiac hypertrophy and arterial sclerosis, and our prognosis will be grave if the condition is at all well advanced.

2. *Albumin.*—A study of the amounts or persistency of this substance affords little light, since in advanced forms of nephritis it may be constantly absent or appear only at times, and is uniformly scanty. Again, the quantity may be large and constant, and the subsequent history prove the case wholly functional. Jaksch[3] warns us that we are not warranted in inferring the existence of a renal lesion from the mere fact that the urine contains albumin. The forms of albumin usually found and always alluded to as of pathological interest, are serum albumin and serum globulin or paraglobulin; these two occur in all albuminous urines in varying proportions, the latter frequently the most abundant.

With these may be associated other and adventitious forms from which they may with difficulty be distinguished. Many find their way into the urine after its secretion, being derived from disintegration of the renal epithelium or due to the presence of blood, pus, prostatic or seminal fluid, leucorrhœa, etc.

Grainger Stewart classifies these albumins as follows: Hæmoglobin, peptone from gastric or intestinal digestion, propeptone, albumoses or globuloses, acid albumin derived from the action of acids on albumin, alkali albumin, fibrin found in hæmaturia, chyluria, and also derived from renal casts, mucin, lardacein, waxy or amyloid material derived from renal casts occasionally. The microscope and clinical history will usually differentiate serum albumin and globulin from these adventitious forms with ease, except mucin, which affords a fruitful source of error as it forms a precipitate with most all the test reagents, and its appearance is favored by the same causes as albumin. Sir William Roberts says it is present in all urines, healthy or morbid. W. H. Washburn regards its appearance as suspicious, and where persistent in large amount it affords strong proof of defect in the renal structures, and may be diagnostically as important as the albumin which it masks. Citric acid is the usual and most delicate test, and should always be used when testing for albumin to determine the presence and proportion of mucin, since this acid does not precipitate albumin. Dilute mineral acids behave the same, but concentrated ones dissolve mucin. Millard mentions as a possible source of confusion the sticky substance found in chronic cystitis, attributed to the decomposition of leucocytes by the urea and ammonium carbonate; the microscope will here prove of service.

The tests for albumin have, of late, greatly multiplied, but coagulation by heat, the oldest, and the nitric acid or Heller's test, next in age, still rank first with the majority of examiners. Grainger Stewart considers picric acid the most delicate and reliable test, whose first use in England he attributed to Dr. George Johnson.[1] From experiments with different urines he shows that this acid gives a more marked and rapid precipitate with albumin than with mucin, which with experience can be easily distinguished, and in many cases minute quantities of albumin may be detected without any precipitate from mucin, even though abundant. Millard recommends the phenic-acetic acid and potash test:

℞. Acid phenic glacial ..... ℥ ij.
Merck's or Calvert's 95 per cent. acid acetic puri ..... ℥ vij.
Add. liq. potassæ ..... ℥ ij., ℥ vj.

Tanret's test, or the double iodide of mercury and potassium, is considered of value by the same author. The nitric-magnesian test discovered by C. Gerhardt[3] in 1856, and modified by Sir William Roberts,[3] consists of one part nitric acid to five parts saturated solution of magnesia sulphate, claimed to be more delicate than pure nitric acid. Other tests are metaphosphoric acid, acidulated brine, potassium ferrocyanide, ammonium sulphate, etc. The percentages claimed for each test are: heat, 1 part in 100,000; nitric acid, 1 to 100,000; Tanret's phenic-acetic acid and potash, and nitric magnesian test, 1 to 200,000. For the accurate determination of the amount of albumin present we have several elaborate methods of separation: drying and weighing, also Esbach's tubes graduated for the urine and reagent, Sir William Roberts's dilution method, and Dr. Oliver's percentage method. Millard says the percentage is usually less than one-tenth per cent., and the most he ever found less than two and one half per cent., an amount he considers never exceeded. He criticises the frequent method of guessing at the amount from the degree of cloudiness, and the statement often made of three and four and even fifty per cent., while the serum of blood contains only three to four per cent., and urine with one and one-half per cent. would become almost solid in testing, and look one-half albumin. Hofmann and Ullzmann offer an approximate, but fairly accurate, method in considering every line of thickness of the white cloud caused by contact with the reagent, to represent one-tenth per cent. of albumin.

In considering the relative values of the different tests, Dr. Victor C. Vaughn[4] states that the only tests which distinguish the albumins from the albumoses and peptones are heat, nitric acid, and acetic acid, and potassium ferrocyanide; Sir William Roberts recommends heat or nitric acid contact; Professor Fraser, Tyson, Pye-Smith, Goodhart all favor the same. A few precautions are necessary in applying the heat test, viz., to render the urine moderately acid, if not so, but not too acid, or we will get an acid albumin not precipitable by heat; acetic acid is preferred for this purpose. Earthy phosphates, if abundant, may give a cloud which should be cleared up with an acid—citric, nitric, or acetic, preferably the latter; but care is required, as when the cloud from albumin is faint the addition of anything will scatter it, and nitric acid will redissolve such a trace.

With the nitric acid test the acid is usually added slowly, drop by drop, but recent writers recommend plac-

ing the acid in the tube first, and pouring the urine gently upon it. Urates in excess may obscure this test, and when so they may be dissolved by heating the test-tube to a point just below the coagulating point of albumin, viz, 140° F. Dr. Munn [1] and others call attention to the fact that this and all contact tests should be viewed by reflected light; the tube should be held at the lower end of the window, the shade drawn down to it and out from the window about a foot, thus excluding the direct light from the eye of the observer; the acid is added while the tube is thus held. Dr. Munn claims that by this precaution many cases will be detected which would otherwise be overlooked, and that he has thus succeeded where the family physician of the applicant for life insurance had failed. He also cautions that the tested urine should stand for five minutes, Millard says ten or fifteen, before deciding, and then if no cloudiness appears the urine is non albuminous.

In concluding this topic I quote from Rudolf von Jaksch,[2] "Serum albumin in notable quantities is never found in healthy urine, and its appearance is in all cases a morbid symptom of great importance."

3. *Urea.*—In this substance we have an exponent of the working capacity of the kidneys. Persistent diminution in the daily excretion of the urea would point clearly to existing or impending organic renal disease. The amount is influenced by the quantity of fluid consumed, kind of food, amount of exercise, and condition of digestive functions. Average daily output should be 550 grains (W. H. Porter).[3] Excretion is diminished by the onset of acute febrile diseases, later increased, and all causes which retard the activity of the hepatic or renal cells, especially the latter, and most markedly by organic renal lesions. Hence in the functional forms of albuminuria the excretion of urea should remain normal. The source of urea is from the destruction of the red blood-corpuscles (Dr. Oliver), and from the food ingested, from nitrogenous most directly, from carbonaceous by a more complex process.

4. *Casts.* The origin of these bodies is in the renal tubules, from an albuminous or fibrinous exudate from the blood-vessels, and they usually incorporate the tubular epithelium in their structure. They are found in most all forms of renal congestion and inflammation in varying amounts, but as to what exact conditions favor their formation, and why at times present and again absent under the same apparent physical conditions, we are unable at present to determine. Usually their discovery is of grave diagnostic and prognostic import, but hyaline, epithelial, and even granular casts have been found in cases which eventually completely recovered and may at the time have appeared in perfect health in all other respects. Charcot [4] states that hyaline casts may be found in normal urine, and many other observers have found them in affections apparently apart from the kidneys; *e.g.*, Nothnagel says he always found them in severe icterus, albumin is frequently found here also; Grainger Stewart reports casts as frequently found in such cases. Allchin does not consider casts as a serious symptom. A cause for error in reports may possibly be mucous casts or cylindroids which have the shape and many of the appearances of hyaline casts, or may receive a precipitate of amorphous urates or lime phosphate, and closely simulate granular casts. Sir Andrew Clark,[5] Dr. Campbell Black, and others report bodies resembling renal casts which were really prostatic casts. Again, Drs. George Johnson and Millard deny that casts or renal epithelium are ever found in normal urine. In my private records I have notes of a case which occurred in a gentleman forty years of age, of fine physique, fond of athletic exercises, especially boxing. Hyaline casts were repeatedly found by the examiners of two prominent insurance companies in this city, and these results confirmed by Drs. Delafield and Janeway. His application for a policy was rejected. Subsequent investigation disclosed that the casts were only present after boxing and absent at all other times. An accessory fact on which much stress has been laid, was, that he invariably followed his exercise with a cold alcohol and water sponge-bath. As to the bearing of exercise on this phenomenon we may cite Weston again, as after his long walk in London, one hundred and fifteen miles in twenty-four consecutive hours, he is reported by Pavy to have had in his urine albumin and casts, hyaline and granular, but twelve hours later all was normal. The case I have related was unique in that albumin was not present at any time. Change in his habits of exercise resulted in disappearance of casts. Six months later he was accepted by both companies, and to day, nine years later, is in perfect health and vigor, fully justifying his acceptance as an insurable risk. Casts have never since been found in repeated examinations. What explanation can be offered for the condition here narrated? Exercise might, where violent, increase the excretory products to be eliminated and so subject the kidneys to a strain sufficient to cause a congestion, and even low grade of inflammation, and so produce casts; but if so why did not albumin accompany? Again, the cold alcohol sponge-bath might affect the renal vaso-motor nerves reflexly through peripheral irritation. This patient was at times markedly oxaluric, and shortly before the casts were discovered, six or nine months, he had a slight urethral discharge, apparently prostatic, which I attributed to oxaluria; now, the same irritation in the kidneys might cause cast formation, possibly.

5. *Specific Gravity.*—If this is high we may safely assume that the kidneys are functionating properly, particularly if the daily quantity is normal; but if the specific gravity remains permanently low, grave organic renal disease is probable.

6. *The Daily Quantity.*—This affords an indication of the filtration activity of the kidneys. The amount is large in waxy or cirrhotic kidney. It is small in obstructive troubles in the urinary tract, also in degenerative conditions of the renal epithelium and in chronic congestion. In functional albuminuria the amount should be about normal, and influenced simply by usual causes, viz., atmospheric temperature and moisture, and by diet. A fair daily output would be 40 to 50 ounces.

As a cause of increased urinary secretion, Porter [1] mentions loss of contractility in the renal vessels, and the full blood pressure, unrestrained by the afferent vessels, being brought to bear on the Malpighian tufts, is forced through the over strained capillaries.

7. *Color.*—This varies from pale or almost colorless, in nervous or diabetic cases, to dark or even black. These grades of shade may depend on the concentration of the urine, and so be of importance to our topic as indicating what the daily quantity should be, or are due to certain articles of diet, certain drugs, or to abnormal products from the patient's own economy, as bile, or blood.

8. *Phosphates, Urates, Chlorides, Oxalates.*—These have already been considered.

9. *The General Personal Appearance.*—This may give some clew to the renal condition in a peculiar pallor, possibly some disinclination to exercise, poor circulation, and transient œdemas of the feet or eyelids, although the appearances with organic lesions resemble these but are more intense.

To sum up, we find as causes of albuminuria: 1. Changes in the renal circulation, viz., venous stasis, the venous radicles and Malpighian tufts being dilated, tension therein increased and circulation slowed; or again, all the renal vessels dilated, arterial, capillary, and venous, with increased rapidity of circulation, that is, an active or passive hyperæmia. In no purely non-organic albuminuria do we have increased arterial tension, except transitory or accidental; if persistent, arterio-sclerosis is developing and the case has become an incipient nephritis.

[4] Bright's Disease, p. 33. [5] London Lancet, 1886, vol. i.
[1] Renal Diseases, p. 205.

These changes in the renal circulation may depend upon cardiac or obstructive pulmonary affections, tumors of the mediastinum or abdomen, causing pressure on the vena cava or other vessels, or lastly, on change in the renal structure. 2. Changes in the renal blood-vessels in all their coats which permit the transudation of albumin, while under normal conditions this would be impossible. 3. Digestive disturbances which produce irritating substances for the kidneys to excrete. 4. Changes in the blood; *a*, surcharge of albumin; *b*, an excess of salts which, Hoppe-Seyler and others consider, favor the exosmosis of albumin; *c*, increased wateriness claimed by some as a factor, viz., Magendie and Mosler;[1] *d*, the opposite condition, undue concentration, is maintained by others, G. Stewart, etc. 5. Reflex or direct nervous influences. 6. Small amounts may be derived from a slightly excessive disintegration of renal epithelium without any pathological import (Senator). 7. Lastly, the adventitious, contingent, or accidental forms from parts remote from the kidneys.

Prognosis.—We find here much difference of opinion. The factors demanding our attention in arriving at a satisfactory and logical conclusion are the duration, persistency, and amount of the albumin, together with the other characteristics of the urine, and the general physical condition and pursuits of the subject.

Dr. George Johnson says, "If albumin is absent during intervals of twenty-four hours consecutively, urine normal in color and specific gravity and no casts, prognosis is good."

Professor Saundby: "He has seen a large number of such cases during the past ten years who have never developed Bright's disease, and many are well."

Pavy: "Where traces of albumin only without other conditions of kidney disease, and especially where present at one part of the twenty-four hours and not others, prognosis good."

Drs. Maguire and Broadbent[2] consider albumin only of importance in a relative manner, as indicating other lesions present.

M. Dieulafoy[3] reports that in sixty renal cases in his hospital wards albumin was absent in one-fourth, and in others albumin disappeared and yet the disease progressed.

Grainger Stewart[4] cites the case of a young man whom he watched through his student career, in the arduous work of a four years' course in medicine, who had albumin constantly in his urine, and yet the work he went through should be sufficient guarantee that his health was not seriously impaired.

Dr. Barnes[5] expresses the view "that the condition indicates a temporary disturbance of the equilibrium of several functions, and the incapacity of certain organs has to be supplemented by the activity of others, and if neglected the condition may become pathological."

Dr. Ralfe,[6] in an able paper read before the London Medical Society, says: "The clinical significance of albuminuria as a symptom has undoubtedly diminished during the last twenty years. By the systematic examination of the urine in all patients presenting in private practice and for life insurance, these cases are discovered earlier and treatment instituted before irreparable damage has been done. Hence, the prognosis is improved." A large number of these cases, he says, eventuate in the red or white granular contracted kidney. In the former, the onset being insidious, the case rarely comes under observation until well advanced, but when seen early much benefit may be obtained by diet and proper hygiene. He cites the case of a gentleman now living, seen first in 1878, for bronchitis, then presenting no abnormal urinary or other symptoms. In 1882, he had hypertrophy of left ventricle and displacement of apex. Pulse showed increased tension; urine, abundant; specific gravity, 1.014, a trace of albumin. Under diet, etc., albumin disappeared, and now, after eleven years, he has a little more outward displacement of apex, a more palpable thickening of the radial vessels, and more constant appearance of albumin and of urine of low specific gravity. So far no serious symptoms have developed, but how long before they may we cannot say. Cases with the small, white, or mottled kidney give more marked symptoms, are seen earlier, and hence offer a better prognosis.

The gouty form, our uric or oxaluric form, Dr. Ralfe gives a favorable prognosis for if under proper diet, etc.; but neglected, the results are often disastrous. The history of a case is given which terminated fatally in four years through neglect of diet, etc.

Albuminuria occurring for the first time in adult life, Dr. Ralfe considers a danger signal, even though no cardiac hypertrophy, etc., accompany and the albuminuria be intermittent.

Dr. W. T. Gaerdner,[1] of Glasgow, expresses much the same view and says that the danger signal is not necessarily fatal, but heeded, may avert disaster. Dukes[2] gives an unfavorable prognosis in all cases at all persistent.

Brannan[3] pronounces that all cases untreated will eventuate in organic renal lesion.

Dr. Pye-Smith[4] considers all albuminurias pathological.

Millard the same. Dr. W. H. Washburn[5] says he considers the condition always pathological and indicates an abnormal state of the kidneys, which may be transitory or permanent, the probability of cure diminishing as it lasts. My own views, based upon cases encountered in private practice, dispensary, and hospital work, also cases examined for life insurance or referred to my care by insurance examiners, have led me to regard these cases with distrust, especially where the cause appears to reside in any persistent fault in the assimilative functions, nervous or circulatory apparatus, and only to relax those feelings when the albumin has disappeared for weeks or months, and the other characteristics of the urine become entirely normal. Undoubtedly, many cases show albumin in the urine persistently for years and never develop any further indications of organic disease, but the natural tendency in even the blandest cases, is to gradually impair the renal epithelium and other structures by the continued abnormal filtration of albumin, and transform a simple functional into a true nephritis. Hence I would pronounce them damaged lives to be carefully watched, our diagnosis to be guarded, and if insured, only in a protected manner. As to insurance, Sir William Roberts and Senator consider these cases as favorable if purely functional. Pavy says, "I do not consider medical knowledge is at present in a position to enable us to differentiate these cases from those which eventually develop into Bright's disease."

Johnson favors an advanced premium. Saundby, as surance for five years and then re-examination. Pollack[6] holds the same view and an advanced premium.

It has been suggested to insure these cases at ordinary premiums, and if they die before the average first-class life limit, to deduct proportionately from the amount paid; but should they attain to the above limit or over, to allow full premiums.[7]

Treatment.—This is mainly dietetic, and regulation of the general hygiene, viz., occupation, clothing, exercise, etc. Diet plain, farinaceous or milk, few meats, and no wines. Keep the kidneys well flushed, using plain or alkaline mineral waters, hot water before meals. Warm bathing and free stimulation of the perspiratory glands. Repeated urinalyses to keep us informed of the working condition of the kidneys, and a watchful care of the heart and blood-vessels. As to drugs, most all observers

have reached the conclusion that they are powerless to check the discharge of albumin, although several will produce it. An occasional hepatic stimulant, as blue pill or nitro-hydrochloric acid, will be of service. By these means a case may long be held in abeyance, and possibly even an entire cure effected.

Case I.—B. L——, merchant, aged forty-five. Family history and habits good. Rejected by insurance company in 1880 because albumin was found in his urine. Height, five feet ten inches; weight, one hundred and eighty pounds. Chest examination, negative. Digestion at times impaired, acid eructations, uncertain appetite; albumin scanty, but uniform. Ordered to travel, light diet, and regular hours for meals. Six months later improved, but still albumin found. Seen three months later, no albumin and general health good.

Case II.—L. McA——, aged twenty-three; seamstress, unmarried. Seen first, in 1881, in hospital. Suffers from dysmenorrhœa, poor circulation, cold extremities, migraine, and attacks of hystero epilepsy. Heart sounds feeble, pulse weak and intermittent. Urine loaded with oxalate of lime and considerable albumin. Treatment: Calomel in grains iij. doses, occasionally. Nitro-hydrochloric acid, and tr. nux vom., bromides for nervous condition. Diet: Milk, farinaceous articles, light meats, and fish. The urine improved with her general condition, but albumin never all disappeared. Discharged after three months, improved. Seen two years later, had remained benefited, but still had a trace of albumin, and showed some hypertrophy of left ventricle. Readmitted to hospital in 1887, suffering from uræmic dyspnœa, rigid and tortuous arteries, marked retinal changes, œdema of limbs, urine contains urates in abundance, albumin, casts fatty and granular. Died two weeks later in uræmic coma. Autopsy revealed small red kidney and general arterio sclerosis.

Case III.—J. W——, horse-raiser, aged thirty-seven. Seen first in 1884, suffering from albumin in the urine, but scanty; backache, nausea, frontal headache. Heart and lungs all right. Treatment: Diuretics, regulation of bowels, and later tonics; and in six weeks all abnormal symptoms, both general and in urine, removed. Seen during the next four years at intervals, remains free from albumin, and in good health. In 1892 seen, after an interval; has been passing albumin for six months, has granular and epithelial casts, headache, rigid arteries, apex displaced outside nipple line, accentuated aortic second sound. Treatment: Diuretics and stimulation of skin and bowels. Improved, but went West in cold weather, and returned much worse, and died of pulmonary œdema two weeks later. This was at the last a case of contracted kidney, but originally was of the functional variety.

Case IV.—Girard L——, seen in 1882 while participating in a walking match, aged twenty-two, formerly telegraph operator, well developed, general physique good. Suffering from great prostration on third day of walk. Urine shows albumin, urates, and phosphate in excess. Ordered to discontinue walk, and all albumin disappeared.

Case V.—Sam P——, longshoreman, seen in 1883. After a severe day's work in the sun in July, was prostrated and taken home in dazed condition; urine albuminous for two days.

Case VI.—George C——, aged sixteen, delicate lad, seen in 1886 during an attack of chorea of great severity; urine albuminous. Chorea improved under Fowler's sol., large doses, and albumin disappeared at same time.

Case VII.—C. K——, painter, aged fifty-two, suffering from bad colic. When seen in 1889 general condition fair. Urine albuminous for three weeks while under treatment, and then disappeared permanently.

Cases VIII., IX., X., XI., all in good general health, but at times show albumin in urine after irregularities in meals, hours, or excess in drinking; have been under observation now, 1, 3, 3½, and 5 years, respectively. General health good.

Case XII.—I. S. L——, Chinese art student, aged twenty two, seen in 1884 suffering from incipient phthisis. Some pulmonary consolidation; urine has albumin and hyaline casts. Under tonics and travel his phthisis was checked, and with it the urine became normal and remains so now.

THE LIMITS AND REQUIREMENTS OF GYNECOLOGY.

By EDWARD W. JENKS, M.D., LL.D.,

DETROIT, MICH.

PROFESSOR OF GYNECOLOGY IN THE MICHIGAN COLLEGE OF MEDICINE AND SURGERY, FELLOW OF THE AMERICAN GYNECOLOGICAL SOCIETY, ETC.

"L'attention a besoin d'être éveillée pour apercevoir même les choses les plus ordinaires."—Dupuytren.

There seem to be two different views quite commonly held concerning the science and art of gynecology; one being that it has to deal only with the distinctive organs of women, and another that the whole of this specialty is a branch of surgery, while everything else pertaining to the illnesses of women either belongs to some other specialty or to general practice. This branch of professional labor which has to deal with the most cherished portion of the civilized world, has a much wider range, and it cannot be thus bounded. With this belief I shall venture to call attention to a few essentials, rather than even attempt to discuss in any full sense the limits and requirements of gynecology.

Ever since Eve quit living at her ease and entered upon her worldly career, down to the dawn of the millenium, there has been and will be numerous ailments of women, whose coming neither the devices of man nor the provisions of nature can avert. The capabilities of gynecology, which has already bestowed untold blessings on the human race, are very great, whose limits and requirements are difficult if not impossible to closely define, and I must confess that as I approach the task I do it with reluctance, for I feel my incompetency to discuss the subject in such a manner as its importance demands.

In the present time, when specialism in medicine and surgery is more common than formerly, and the value of special study and training are universally acknowledged, the following questions arise: Is there not a great liability that specialists will fail to be thoroughly educated in general medicine and surgery prior to entering on special work? Is not a thorough practical knowledge of medicine and surgery an important pre requisite to success in special practice? The foregoing interrogatories will be incidentally considered in the following paper.

Specialism in medicine has become recognized as a necessity not by the profession only, but by the people. The high school graduate of to-day represents attainments equal to the college graduate of a quarter of a century ago. Knowledge has increased with the growth of the century, in medicine as in all other branches of learn-

ing, and the medical student of to-day has facilities for obtaining knowledge which were unknown a few years ago. There is now no excuse for a graduate in medicine being uncultured and uneducated, yet with all the means at command for thorough medical training, it is beyond the capabilities of the human mind for one to be equally proficient in all the various departments of our art. It would be like whirling the wheel of time backward for us to return to "the good old times," when a doctor was supposed to be equally skilled in general medicine, surgery, obstetrics, and all of the specialties developing therefrom.

It can be stated without fear of contradiction, that it is impossible for one person to embrace the whole of the professional field in practice. Life is too short for one to attempt to plough equally deep in each. This is more palpably true as they severally demand the highest culture.

It is to be deplored that specialists often engage in their work without adequate preparation, and sometimes medical students select some special field of labor and upon graduating enter immediately upon its practice. Thus both general and special medicine are brought into disrepute, for no one can graduate into a specialty.

I have for years contended that the only material from which to make a successful specialist is the general practitioner, and time has more strongly confirmed my belief. First, a thorough medical education, and secondly, several years of general practice, should precede engaging in special practice. The aptitude one may evince for a particular field of labor may often be an entirely different one, at this time, from the one aspired to in student days.

Gynecologists, no less than general practitioners, are cognizant of the fact that women patients may be affected with other disorders than those of the uterus and its appendages. It cannot be denied that there has been an apparent forgetfulness, on the part of some practitioners and some gynecologists, that women possessed other important organs than those contained in the pelvis. There are many derangements of the system which closely resemble diseases of the generative organs. For instance, pain in the back may be due to coccygodynia or myalgia, chronic malarial toxæmia, or other causes. Painful micturition, often attributed to uterine displacements, may be due to irritable caruncle of the meatus urinarius or fissure of the urethra. And when the painful urination is accompanied by pelvic pain, one might be led to believe the discomforts were due to uterine displacements, or possibly cystitis; yet analysis of the urine will show a uric-acid diathesis which neither the washing out of the bladder nor any other local treatment will relieve. Pain in the abdomen, sometimes attributed to the ovaries, may be due to habitual constipation or to an atonic condition of the large intestine. Sometimes the pain in the left side, called ovarian, may be wholly due to constipation. In this condition there will be, not infrequently, pain in walking or standing. Pelvic congestions, reflex disturbances closely simulating diseases of the uterus, diseases of the rectum, hæmorrhoids, anal fissure, ulceration of the large intestine, may produce symptoms often attributable to diseases of the generative system.

Without question, chronic constipation with the consequent pressure upon the left ovary, is one of the most frequent conditions giving rise to ovarian pain, with many reflex symptoms, such as sympathetic sciatica, so closely resembling ovarian disease as to be called by the latter name. There is but little room for doubt that the long continuance of pelvic disorders will in time give rise to hæmorrhoids and other disorders of the rectum; and on the other hand, these last-named conditions may aggravate already existing pelvic disorders.

There are many abnormal conditions of the abdomen closely resembling diseases of the uterus or its appendages, such as movable or displaced kidney, a sensitive or slightly inflamed condition around the appendix vermiformis, chronic exudation around the same, inflammation of the ureters. Malignant disease of the kidney, calculus, pyonephrosis, and other diseases of this viscus may simulate uterine disorders. The same may be said of tubercular peritonitis and certain affections of the stomach and colon. Hepatic disorders are frequently mistaken for uterine, while the reverse also holds true. Displaced liver has lately been mentioned as having been confounded with uterine disease.

Other constitutional diseases, having no immediate connection with gynecology beyond the fact that the patients are women, may be by the imperfectly trained gynecologist claimed as belonging exclusively to his specialty. Other conditions arise where a clear and definite acquaintance with diseases of the chest, and a practical knowledge of auscultation and percussion, are essential to the gynecologist.

The astonishingly brilliant achievements of abdominal surgery of late years, has brought this department into great prominence before the medical world. The per centage of recoveries of the successful operators has become so large that its recital would have seemed a fairy tale to the ovariotomists of a quarter of a century ago. While it is a laudable ambition to make many operations, and especially have a large percentage of recoveries, there is a much higher aim; that is, to cure the patient; and it is a well known, but not generally acknowledged, fact that recovery from an operation and cure of the disease are *not* synonymous terms. The subsequent history of many of those operated upon would often be a sad recital of aggravated suffering. This is a grand central question around which many things turn. It is a melancholy truth that tyros in the profession, so far as general medical knowledge is concerned, have become expert abdominal surgeons and have acquired proficiency in technique, but without the diagnostic skill which should accompany it, and which some experience in general medicine alone furnishes. Such men as these are not fair representatives of the best gynecologists of the present time.

Further, these surgeons frequently point with pride to the great number of recoveries, yet many of these reputed recoveries are not *cures*, as subsequent results show. Removal of the ovaries and Fallopian tubes for pain, *per se*, has not been productive of many cures, nor has the same surgical operation for mental disorders been more satisfactory. It is very evident to every conscientious, careful gynecologist, that anæmia, the multiform varieties of neurasthenia and hysteria, play an important part in the production of pain.

These are misleading conditions for which many a woman has had her ovaries removed, without accomplishing the ultimate good results usually expected, and often promised.

Thirty years ago, the teachings of Bennett regarding ulceration of the uterine neck, which we now know is not true ulceration but granulation following laceration, represented the advanced views of that day. Then, the mechanical treatment by means of pessaries held the boards for many seasons. An epitome of the practical portion of one of the most interesting and elegantly written American works on diseases of women, can be given in few words, viz., "All curable diseases of women can be cured by my pessary, while those that cannot be cured by this means are incurable."

Then later, the crooked ways of the uterus must be made straight by stems, tents, cutting instruments, etc.

At another time the incision of the uterine neck for a variety of disorders was in vogue, while later, the neck of the uterus was found to be torn after every case of childbirth, and could only be remedied through a surgical operation. Thus many of the fads of gynecology have from time to time prevailed, to be relegated later to the things that have been.

More recently, a new school of gynecological prophets has arisen, who have promised ease and comfort to all suffering women if they will submit to a trivial surgical

procedure, and be content to remain ovariless and child less during the remainder of their lives. The old classical motto, "Propter uterum est mulier," is no longer held in esteem, but in its place, "Propter ovaria est mulier," with the addition in plain English "For revenue only."

Happily for the future of our country, this industry is diminishing, and conservatism is beginning once more to hold sway; and as it is quaintly put by the brilliant editor of the MEDICAL RECORD, "What glad news this will be for the little ovary, which can now carry on its particular home industry, instead of becoming domesticated into the pickling jar of the progressive gynecological pathologist. Let us hope, then, that the surgical millennium is coming, when the ovary shall hereafter peacefully wrap the drapery of the broad ligament about her and lie down to peaceful dreams of families yet to be."

One characteristic of many in this new school is the apparent assumption that all gynecological knowledge worth retention has been developed by them and is an outcome of the last decade. The literature of the past is rubbish, its pathology faulty, and its teachings pernicious. Libraries are no longer of value, and only recent publications, damp with the printer's ink, are to be relied upon. It cannot be forgotten by the conscientious observer, that the present state of gynecological knowledge has not been altogether the result of sudden development, but rather the product of slow accretion. The student of medical history, however, finds it often repeating itself, and the revival of some old fact or theory is modernized with additions and given to the world as something entirely new.

Let me not be misunderstood. No one admires more than I do the pushing aggressiveness of many of the very class I have alluded to; but the belief that true conservatism, based on thorough knowledge, should prevail has prompted me to write thus plainly. Conservatism as applied to gynecological surgery, is a term sometimes used as an excuse for ignorance or inefficiency, but it is only in its true sense that it is here used.

It is neither my desire nor design to deprecate the value of surgical gynecology. Since my first ovariotomy, in 1868, I have been constantly engaged in the surgical work of this specialty, therefore it is from the standpoint of the surgeon rather than the physician that the theme I have selected is considered. If what I say concerning gynecological errors can be looked upon as a criticism, then I may be among the criticised. It seems to me that, from the gynecologist himself, no more appropriate plea can emanate than one which demands that knowledge in his specialty shall be limited alone by the most thorough scientific attainments and cultivation of the highest art.

Materia medica comes in for more than its share of ridicule by this newest school, and yet a knowledge of therapeutics which implies a certain degree of familiarity with materia medica is an important pre-requisite for the thoroughly equipped gynecologist.

The changes in theory and practice have been more marked and more rapid in gynecology than in any other department of medical science. These changes have not been continuously progressive, but have been fitful and somewhat erratic. The accusation has been made, and not wholly without good cause, that gynecologists often fail to understand clearly the influence which disorders of the generative organs have upon the general health. The foundation of these charges, doubtless, lies mainly in the fact that the work of most gynecologists is in the main surgical instead of medical. The aims of surgery are for direct results, while those of medicine are more remote, reflective, and more comprehensive in character. During the past few years abdominal surgery has accomplished such astounding results, that it has seemed to many gynecologists to overshadow everything else. The unprecedented number of recoveries from cœliotomies at the hands of gynecological surgeons, has brought this branch ot surgical art and science to the front in such a manner as to lead to the belief, on the part of many, that not only is proficiency in abdominal operations a *sine qua non* for every full-fledged gynecologist, but more particularly is the number of his operations a gauging point.

In other words, the more cœliotomies, the higher in the scale is the gynecologist, and the quicker they are made, the more lustre is added to his name. That this branch of gynecological work has apparently overshadowed everything else, is to be deplored, and it must, in the near future, lead to many retractions and many regrets. It does not seem possible for it to be otherwise, unless the usual currents of medical and surgical history deviate from their regular channels. "Tithing mint and cummin, and neglecting the weightier matters of the law," has its parallels in medicine as well as elsewhere. Of this assertion it may be asked, which are the weightier matters, and have you not reversed the proper order in which they should be placed? It is not necessary for the purposes of illustration that a decided answer to this question be given, as there must of necessity be honest differences of opinion as to what should rank first in importance in gynecological work.

In the rush to become distinguished as abdominal surgeons, some seem to have neglected the careful study and consideration of many of the morbid conditions to which the uterus and other organs are subject, and for which cœliotomy is never required.

The many improvements in the diagnosis of diseases of women and the surgical operations for their relief, have been the most distinctive features of the progress of gynecology during the present generation. McDowell initiated the surgical procedure from which the most brilliant results have followed and thousands of lives have been saved. Probably no other operation has been devised which has added so much to the duration of life as ovariotomy. We find here an illustration in its highest sense of conservative surgery. The injuries of parturition which formerly were considered beyond the resources of art, are now cured by surgical means. The éclat of surgical operations often brings reputation and pecuniary compensation out of all proportion to the rewards of patient labor in the fields of pathology and therapeutics. For these reasons it is not surprising that medical gynecology has failed to be as attractive as surgical. Genius has exhibited its triumphs more frequently in surgical gynecology. But the shining successes of surgery are of necessity accompanied by tendencies more or less dangerous, particularly where enthusiasm for the work develops a spirit of recklessness sufficient to cause one to forget that an operation is never justifiable except for the preservation of health or saving of life. "The sole justification of any operation which involves suffering and danger to the subject, must be the strong probability, based on scientific knowledge, that compensating good will be the result." (Fordyce Barker.)

The temptation to practise our art when the conservative processes of nature may effect a cure, sometimes leads one into error. It is impossible to defend a death caused by an operation performed for the purpose of relief from symptoms which have but little disturbing influence upon the general health.

Abdominal surgery has attained such prominence that it seems to be, by many in the profession, synonymous with gynecological surgery. In this class of work the advantages of skill in operating and nursing, with suitable environments, have been made apparent, and it is through them that the present great successes of abdominal surgery have been attained.

I heard a well-known and distinguished general surgeon remark, in a gathering of medical men less than a year ago, that gynecology was simply a branch of surgery and should never have been separated from it as a specialty. Others think differently, for the general surgeon, although he may be skilled in the technique of certain operations, is not from that fact a gynecologist. There is preliminary training before entering upon practice that

the surgeon is not required to pass through. The delicacy of touch and gentleness in methods of manipulation are better acquired by the obstetrician than the general surgeon.

Doléris, the distinguished French gynecologist, goes so far as to say, "One is not a gynecologist if he has not begun by being an obstetrician." This position he defines in an elaborate paper.

Substantially the same views are held by Auvard, of Paris, Martin, of Berlin, and Winckel, of Munich, in an exhaustive paper read at the last meeting of the American Gynecological Society, on "The Union of Obstetrics and Gynecology."

Similar views to the above are also entertained by many who have become distinguished in the field of gynecology in England and America. While such opinions may be deemed radical, it cannot be denied that they contain more than a modicum of truth; nor is it necessary to read between the lines to observe that a one-sided development does not make the well-rounded and competent gynecologist.

The lessons taught by history are not always comprehended nor remembered, and that is why mistakes of the past repeat themselves. We have been taught by medical history that errors of observation and judgment have ever accompanied the truth, and that its progress has been marked with dazzling delusions, some of which were in their time believed to be as substantial as any established fact of to-day. Errors are never suddenly abjured. One is slow to renounce old beliefs, but time is an element that frequently works great changes. It may be a little humiliating to look back upon discarded follies, but there will sometimes be great advantage in retrospection. We profit more by our own mistakes than by those of others, but we should also attempt to gain knowledge through the history of the past and the successes and errors of others.

I believe it to be an established truth in medicine as elsewhere, that one gains more useful knowledge through his failures than his successes.

Conservatism has not always met with the consideration due to it. In our art conservatism, in its true sense, signifies the preservation of health and saving of life by the least dangerous means, but if necessity demands, the most effectual and radical treatment should not be avoided. It is not conservatism to attempt to disperse a pelvic abcess by tampons and hot douches, nor to endeavor to cure an ovarian tumor by electricity. True conservatism demands the best and promptest means of treatment.

It cannot be questioned that in gynecology there has been much needless and reckless surgery. It is a surgical sin to make an operation attended with the least danger and causing mutilation, if safer methods will accomplish all that surgery can make possible.

Now, on the other hand, the temporizing methods of those who call themselves conservatives are to be deprecated. Conservatism here is a misnomer. Procrastination and hesitancy, or lack of knowledge and want of courage, are not synonymous with true conservatism. These are the methods, not infrequently, of the timid or the ignorant, and no more represent the genuine gynecologist than do those of the reckless surgeon. There are abuses and errors to be corrected besides those of a strictly surgical character, not the least one of which is the too common and often unnecessary pelvic examination of young and unmarried women. This topic I will dismiss with a single assertion, leaving much to be implied, in saying that the conservation of the *morale* of patients is a duty under that unwritten code which should govern the lives and actions of every physician.

Many patients, and particularly those who consult gynecologists, instead of requiring the knife of the surgeon or the preparations of the pharmacist, are in need of the kindest advice and sympathy. Their minds are emotional, their ideas are disorded, and their sensations abnormal. A study of psychical, no less than physical, disorders is an essential part in the education of one who aspires to any degree of proficiency in differential diagnosis. We have to deal with the mysteries of life, which are intensified when its manifestations are abnormal.

My preceding remarks have been in the main relative to surgical gynecology, and for this reason, that the belief, both in and out of the profession, has seemed to prevail that the gynecologist is a special surgeon, and nothing more.

It is true that to be successful in this branch of medicine one must be a surgeon, but he must be something else. The limits of gynecology are *not* narrow, but wide, and to be thoroughly competent requires a general medical and surgical training. In these days a medical education presupposes preliminary training and culture as initiatory to its study. Medicine can only be advanced in its various branches by its students devoting their entire time and energy to that purpose. I believe it to be impossible for one to deserve eminence in any one specialty without being grounded in the whole science and art of medicine.

Mill, in an address to the University of St. Andrew some years ago, said: "It is the utmost limit of human acquirement to combine a minute knowledge of one or of a few things with a general knowledge of many." This general knowledge marks the accomplished, skilful gynecologist.

To succeed in the treatment of diseases of women, one should fully understand their mental peculiarities as well as their physical conditions, and, all other things being equal, the one will best attain this end who is the best able to bespeak their confidence and stimulate their hope.

Recently the medical journals have called attention to an enterprising young physician, not quite twenty-one years of age, living in a country village in one of the Southern States, who had made eleven laparotomies within a few months, thereby depriving the same number of women of their ovaries, and all these patients had recovered. If gynecology required nothing better than this, what brilliancy is here displayed, what genius, like the rose born to blush unseen, is permitted to languish in that southern village. Probably, in five years nine out of those eleven women will arise and call him not blessed, but cursed.

What a marked contrast is the record of those who have made American gynecology famous. The genial and gentle Marion Sims, of precious memory, was first a cultured gentleman, next a general practitioner in Alabama, and later, through his earnest labors for the relief of suffering womanhood, justly won the distinctive title of the "Father of American Gynecology." The Atlees, Peaslee, whose classical work on "Diseases of the Ovaries" has never been surpassed; Byford, industrious and painstaking; Albert Smith, Jackson, and others who have passed to their reward, were all first general practitioners. Of many now living who have given renown to American gynecology, some were for a time obscure physicians who later developed an aptitude that made them skilful in their special work. None of these who have conferred lasting benefits upon womankind became specialists until, through years of patient toil, they won the right to that distinctive title.

The mantles of the illustrious dead who made American gynecology famous have fallen on worthy shoulders, and future generations will accord to many now living, places in the niche of fame as high as the highest of those pioneers who wrought carefully for years in the field of medical science and now rest from their labors.

The ideal gynecologist is made, not born, nor is the process of construction limited in time by any college curriculum. Before proceeding further in considering this portion of my theme, I want it to be distinctly understood that I am strictly impersonal, as I consider myself sadly lacking in many of the qualifications which go to make up the ideal gynecologist.

To the obstetrician and the gynecologist the dearest interests of the community are intrusted; the ideal gynecol-

ogist should therefore be, first and foremost, a cultured, educated gentleman, worthy of the important trust committed to his care. He should be thoroughly trained as a general practitioner and engage for a time in general practice, for without such experience he will be only a partially grown specialist.

He should be a physician and a surgeon with a general knowledge of all the special branches of practice. He should receive special training at the hands of several masters, for, although the pioneers of gynecology won distinction without it, the times have changed, and now the responsibilities of the specialist are greater than ever before. The improved methods of teaching in the medical colleges and post-graduate schools, with increased clinical opportunities, compel the specialist to avail himself of these advanced methods. The interest in everything that relates to the most cherished members of society, must cause the gynecologist to avail himself of every opportunity by which knowledge may be deepened and broadened by contact with the master minds in this department of medicine and surgery.

It is the right and privilege of every man and woman to aspire to perfection of character and to the attainment of absolute truth in art and science, but their possession is only for Infinity. It is ever the unquenchable desire of higher humanity to strive to reach the summit of human possibilities, and though one may ascend height after height and yet not reach it, he can still bear within his breast this best of all convictions—the higher the aim, the greater the attainment.

Progress of Medical Science.

The Treatment of Gangrenous Hernia.—The proper course to pursue when the contents of a strangulated hernia are found to be gangrenous, was again the subject of recent discussion at the Royal Medical and Chirurgical Society. A paper on this subject was read by Mr. Kendal Franks, of Dublin, who related a case which had occurred in his own practice, and presented a table of 222 cases of gangrenous hernia in which resection of the bowel had been performed. The mortality in these 222 cases amounted to forty-eight per cent., while in a rather larger number of cases in which the surgeon had contented himself with making an artificial anus, the deaths amounted to eighty per cent. Largely on this ground, Mr. Franks urged that the old operation of Lawrence should be, as a general rule, abandoned in favor of immediate circular enterorrhaphy. This view was practically unanimously supported by the surgeons who took part in the debate, and it may be taken to be the view of the more advanced surgeons of the day.—*The Lancet.*

A point of great importance in this discussion was raised by Mr. Thomas Smith, when he stated that "gangrenous bowel" was a phrase which had a different significance to different surgeons. It is very difficult, even if it be possible, to say exactly when the bowel passes the line which separates recoverable from fatal congestion and stasis. All surgeons of experience have met with cases in which the congestion of the bowel has been so extreme that they have doubted whether the bowel was capable of recovery, but on returning it into the peritoneal cavity an uninterrupted convalescence has followed. This being so, the question naturally arises whether the cases in Mr. Franks's table are exactly comparable with those in which the surgeons have felt compelled to make an artificial anus and do nothing more. For our own part we should be inclined to answer this question in the negative. In many cases of gangrenous hernia the general condition of the patient is so bad that it would be impossible to submit him to such an operation as intestinal excision and suture; even the simplest procedure is often enough to extinguish the feeble spark of life. For these grave cases we cannot think that excision will ever be applicable, nor will any surgical measure avert death; but in the borderland cases and in cases of early gangrene it is different, and Mr. Franks's table shows that resection and suture of the bowel may under such circumstances be undertaken with a very great measure of success.

When the operation is determined upon, the question arises whether it is to be effected at the site of the hernia or through a median abdominal incision. In umbilical hernia, of course, these are one and the same. In inguinal hernia the herniotomy wound will generally afford ample room, but in femoral hernia the limits of the crural canal are so narrow that it may be necessary either to divide Poupart's ligament or to make an anterior abdominal incision. Borella, of Novaro, reported such a case about a year ago, but the ordinary laparotomy wound gives much more room, and in many cases would be preferable. Any special clamp may be dispensed with whenever a good assistant is available. The excision of the bowel must be free, but care should be taken to divide the bowel on the upper side, wide of the gangrenous part, so that the stitches shall be made in healthy tissues and not be liable to slough or cut their way out. Great care ought to be taken in every case not to infect the peritoneum from the sloughy hernial sac. All the morbid tissues should be removed before the parts at the neck are much disturbed, and the antiseptic douche should be freely used. To insure success in an operation of this kind adherence to the following four rules would seem to be necessary—viz.: 1. Do not infect the peritoneum from the hernial sac: 2. Excise the bowel well above the gangrenous part. 3. Unite the two ends of the bowel securely with a strong, fine aseptic suture; and, 4. Operate expeditiously; time is of importance, especially if the patient is suffering from collapse.

Bronchial Septicæmia in Infants.—Drs. Hutinel and Claisse have published observations on a form of acute septicæmia observed in young infants, which they believe to be due to rapid infection of the bronchial mucous membrane by micro-organisms derived from lesions in or about the mouth or pharynx. The cases occur frequently as complications of measles, but sometimes arise independently. They are particularly likely to arise in hospital wards when an extensive epidemic of measles has led to crowding. The infant, without obvious cause, becomes rapidly extremely ill, the face is pale, and of a leaden color, the eyes sunken, the cheeks blotched with red, the expression anxious, the alæ nasi work, respiration is hurried, the pulse rapid (150 to 180), and the temperature rises quickly to 104° F. Auscultation reveals numerous subcrepitant râles; there may, however, be no dulness, and the extent of lung occupied by râles may be no greater than a few days earlier when the patient did not appear very ill. Vomiting and diarrhœa of gray-green stools may be present. In a large number of such cases an infective process may be observed on the lips—cracks with a grayish bottom and indurated surface, especially on the upper lip. From these cracks a superficial serpiginous ulceration extends; the lower lip is excoriated and covered with pultaceous sordes. The buccal mucous membrane is red and bleeds easily, the pharynx is red, the tonsillar crypts are filled by a creamy exudation, the nose runs and the discharge excoriates the upper lip. The prognosis is exceedingly bad. In a considerable proportion of such cases no pneumonia is found after death. The mucous membrane of the larger bronchi is inflamed, and this inflammation may extend to a greater or lesser distance toward the smallest bronchi, which, however, are not uniformly affected. The liver is enlarged and presents extensive fatty degeneration, affecting especially the portal side. Bacteriological examination of the contents of the bronchioles showed that a streptococcus was present in every case but one, and generally in large numbers, sometimes in pure culture. In one case the pneumococcus was present alone, in others the streptococcus was associated with staphylococci or the bacillus coli. The streptococcus was in an extremely virulent state. In three cases only was the streptococcus

found in the blood, and the pneumococcus once. As a rule the bronchial glands, liver, kidneys, and spleen contained no microbes. The symptoms, the authors conclude, are produced by the absorption of soluble poisons elaborated by the streptococci in the bronchi and bronchioles.—*Revue de Médecine.*

Encysted Dropsy Associated with Pelvic Abscess.—Hönck reports two cases of encysted dropsy or serous perimetritis. (*The British Medical Journal.*) The patient in the first case had been delivered six months previously and suffered from parametritis. The exudation diminished, on free application of ichthyol-glycerine, to the size of a hen's egg. The patient sought relief because the swelling became larger, with slight rise of temperature. Ichthyol proved unavailing; a parametric "abscess" was found to the right of the uterus. Poultices were applied to the hypogastrium; but the suspected abscess did not come to the surface, so tapping was performed and a clear serous fluid escaped. A month later, as the growth had become larger, abdominal section was performed. The swelling was found to lie between the parietes and strongly adherent coils of intestine. The abdominal incision was closed, and the swelling was opened above Poupart's ligament. Over two pints of clear serum came away; then a spherical tumor was exposed and incised, about a pint of pus escaping. The cavities were drained and the patient recovered. The second case occurred in association with left perimetric abscess in a woman aged fifty-two. The uterus was not fixed. Douglas's pouch, where the swelling presented, was punctured, serum escaping. It was punctured again higher up and more to the left, and then pus came away. In order to open the suspected abscess freely the thermo cautery was used, and, instead of pus, one hundred grains of ascitic fluid were emptied out of the vagina. The abscess was then found to be higher, and was difficult to feel from the vagina. After a short space of time the abscess was freely laid open by abdominal section without cutting into the peritoneum. Drainage was established through the vagina and through the abdominal incision, but the patient died of septicæmia. In both these cases there was a large encysted ascitic tumor associated with suppuration in the peritoneal cavity.

Ophthalmic Migraine.—The history of a case of ophthalmic migraine in a man of forty is given by Evangelista, in the *Raccolitore*, May 10–20, 1893. Ophthalmic migraine exists in two forms that may develop successively in the same subject. The disease is hereditary and appears in families where there has been gout, arthritic or nervous disease. Pathogenesis may have to do with a functional lesion not localized in any special point, but disseminated throughout portions of the cortex. Like Möbius, the author considers ophthalmic migraine a form of sensory epilepsy, and advises the use of bromide of potassium as a remedy, according to Charcot's teaching.

Psychical Contagion in Schools.—Dr. Rembold, of Stuttgart, describes a peculiar psychical outbreak. He was lately called to a school for girls in consequence of one of the little pupils having fallen back, in an unconscious state, on the form on which she was sitting—an incident which was followed in a few minutes by others of the class fainting away, while others again broke out into crying and trembling fits, those who could articulate complaining of feeling very ill. The alarm and confusion arising from this strange occurrence spread to the other classes, in one of which a girl thirteen years of age manifested the same nervous symptoms which had been already witnessed in the first class. On Dr. Rembold's arrival he found among the forty little girls affected that ten were quite unconscious, seemingly sunk in profound slumber, a condition from which they could not be aroused, even with violent shaking and when loudly called upon by their names. Of those who retained consciousness he describes some as trembling all over, weeping and sobbing aloud, while others of them seemed to be dazed and terror-stricken at the sudden illness of their schoolfellows. These latter were immediately relegated to another room and the agitated ones were brought to an open window, and with every encouraging and reassuring word and deed were made to draw deep breaths of the fresh air. Those who were still in an unconscious state were brought round by strong douches of cold water and energetic appeals to them by name, after which they were sent home, whence, either later in the day or next morning, they returned to school without apparently any serious after-effects from their seizure. The interesting point in this noteworthy outbreak is the spread, as if by contagion, of the nervous or convulsive symptoms from individual to individual and from class to class—a phenomenon amply attested as having occurred in previous centuries and which has been variously classed as St. Vitus's dance in Germany and as typhus cerebralis convulsivus by Italian physicians. In these days the name for it is auto suggestive seizure, the peculiarity in the cases reported from Stuttgart being, as Dr. Rembold points out, the extraordinarily short period within which the symptoms arose and disappeared.—*Berliner Klinische Wochenschrift.*

Clinical Department.

A CASE OF ILEUS CURED BY LAPAROTOMY.

By B. S. TALMEY, M.D.,
NEW YORK.

The following communication of a case of ileus cured by laparatomy is not aimed at proving the fact, familiar to every surgeon, that the only prospect of success lies in the knowledge of the impediment in the passages, and its removal by laparatomy, and that any other treatment is insufficient, but it aims at proving the importance of early diagnosis and of timely operation by a surgeon summoned by the attending physician. The number of successfully operated cases of ileus is steadily increasing since the introduction of Lister's antiseptic treatment. Nevertheless every sincere surgeon gives a very doubtful prognosis with reference to the proposed operation. The prognosis would be much less doubtful if the attending physician would understand the disease in time, and not think of ileus until peritonitis or even a collapse have set in, when surgical aid will come too late. I do not deny the correctness of the attempt at overcoming the impediment during the first days of disease by injections into the intestines, irrigations of the stomach, and even by strong cathartics; our case, however, proves the great amount of care to be taken, and the necessity of surgical interference, even when the condition does not appear to cause alarm. The case will be now briefly narrated, as follows:

On August 25th, I was called to see Mrs. Z——, aged twenty-six. The patient had had no movements of the bowels since August 22d, and was now suffering from excruciating abdominal pains. Upon inquiries I learned the following history:

In February, 1891, the patient, having given birth to her first child a year before, suffered from cramps and pain in the ovarian regions, which were entirely relieved for two months at the German Hospital of this city by the alleged removal of the right ovary. After leaving the hospital, however, she did not feel very well upon resuming hard work. During the five months following the operation the menstruation had ceased. It then became so abundant that it resembled a miscarriage, which the patient insists had occurred. On account of pain and leucorrhœa she was examined, and a prolapse of the uterus was found. She was operated upon again, and since this operation the menses have been irregular, occurring every two to three weeks, and she suffered from frequent pain in the ovarian region.

Present Condition of Patient.—Slender woman of healthy appearance. The abdomen is soft and without

signs of dulness upon percussion. Palpation causes pain only in the ileocœcal region. A scar from a former operation runs from the navel to the symphysis. Besides the above mentioned abdominal pain, the patient suffers now from the same cramps as those before the first operation. They appear every five to ten minutes in paroxysms. Her features are distorted as if by pain. The spinal column is extended so as to place the patient into a sitting position. The arms are thrown backward, the fingers are in a convulsive position, half stretched, half bent. After two to five minutes, the patient sinks upon her couch. She vomits everything she takes, and had no movements of the bowels for three days.

The patient having taken of peaches on August 22d led me to believe that all the symptoms were due to simple constipation. The excrements were, I thought, pressing the ovarial scar, thus causing the spasms. Apart from the hysterical convulsions, there was nothing to remind one of a serious disease. I ordered five doses of calomel of ten cent grammes pro dosis (0.01).

In the morning of August 26th I found no changes. No movements had occurred. She had taken three doses of calomel without vomiting it. Since she mostly complained of the spasms, I made a hypodermic injection of 0.01 morphine and ordered enemata.

On the same evening the spasms had ceased, after the injection of morphine, but not the abdominal pain. Stools did not appear, in spite of calomel and enemata. The patient was now unable to pass flatus. The vomited masses looked greenish yellow. The abdomen was still soft and not distended by gases, but the patient now localized the pain in the region of the stomach.

My diagnosis, ileus, which I had considered at first in the morning, was now firmly established. I could, of course, not exactly localize the lesion. But I presumed that the impediment was caused by adhesion of portions of the small intestines to the abdominal scar, thus obstructing the passage. I was positive in not locating the impediment in the large intestines, since after one injection of two quarts of fluid into the rectum, where it remained for three hours, I could feel the fluid up to the cæcum. I still tried another laxative (tinct. rhei) and ordered chloral hydrate for sleep.

On August 27th the condition was somewhat changed. The temperature had risen, the pulse was vigorous, and the abdomen was somewhat distended. The pain was in the entire abdomen. Spasms set in again, for which I gave another morphine injection. I did not feel like delaying the operation for a longer period, and called Dr. Carl Beck for consultation. Dr. Beck believed that same afternoon that we could wait until the next day, since the condition was not so dangerous as to require an immediate operation. We agreed to try once more strong cathartics and irrigations of the stomach. I made a hypodermic injection of 0.005 morphine, ordered one drop of ol. croton, and made two irrigations of the stomach, at 8 P.M. and 11 P.M.

On the following day the irrigations and croton oil had no effect. The abdomen was now somewhat distended. The temperature in the rectum 105.8° F. I sent the patient immediately to the Post-Graduate Hospital for operation.

On August 28th, at 10 A.M., the operation was performed. Since Dr. Beck was also of the opinion that the impediment was due to an adhesion to the cicatrix in the abdominal wall, the cutaneous incision was made just in the old scar. As soon as the peritoneum was opened two hundred to three hundred grammes of serous fluid was discharged, and the convoluted small intestines pushed forth. Along the old scar nothing abnormal was found. The presumption of a location of the impediment, therefore, in this region was erroneous. The small intestines were then examined in the region of the right ovary, and they were found as follows: A convolution of the ileum was found to be adherent to the cicatrix produced by the removal of the ovary. The adhesion was probably caused by an abscess after the first operation. The convolution had the form of a Latin M. The cicatrix was situated across the M in such a manner as to touch four spots of the convolutions. In handling the intestines the fixation was loosened, and the ileum showed a loss of substance at four different points. The two spots in the centre were only deprived of the serosa, and therefore were powdered with iodoform. The external spots had also lost the muscularis and the continuity was formed only by the mucosa. Perforation was therefore only a question of a few hours. These external spots were sewed, the intestines pushed back into the abdomen and the abdominal wall closed by sutures.

The patient had four stools by the next morning, in spite of the administration of opium. The pulse was of normal quality, but somewhat accelerated. There was but slight fever, and the patient felt hungry. The course of the affection was normal after the operation. On the fourteenth day after the operation the patient was discharged as cured.

The above-mentioned condition found during operation explained the symptoms. The peristaltic movements of the fixed ileum caused irritation of the old ovarian scar. The same spasms were thus caused, as those before the operation, by the ovarian tumor. The case is very instructive with reference to the importance of an early operation, even in so-called slight cases. The condition of our patient was so little alarming that I was wondering at the prompt obeyance of the relatives to my orders to send the patient to the hospital for operation. Nobody who had seen her on that morning, especially after the spasms had disappeared by the administration of morphine, could have considered the case to have been extremely serious. And yet the perforation of the ileum was imminent on the same day, and would have certainly occurred if it had not been prevented by the operation.

140 West Sixty-third Street.

[illegible] but little was done until a few months ago, when the National Health Society opened classes for the benefit of the aristocracy, at which something more is taught than a coquettish arrangement of caps and aprons. The idea is to teach ladies the value of good nursing, and enable them to learn something about fit food for invalids and how to give first assistance to the injured, in all of which, it seems, duchesses, countesses, and the like are lamentably deficient.

We fear that fashion has done almost too much for English nursing. Some specimens wander over to this country. They are usually well trained, but carry themselves with such a conspicuous air of self-restraint and such obtrusively repressed gentility, that it does not seem right to ask them to empty the urinal. Good breeding is an excellent and, indeed, indispensable thing for a nurse, but our English sisters seem to carry it on their sleeves like the other insignia of their office. So we say that perhaps fashion has made nursing too fashionable.

SERO-THERAPY.

The treatment of disease by means of injections of serum has been employed so extensively that the term serum-therapy is applied to it by Dr. Ed. Égasse in a critical review which appears in the *Bulletin général de la Thérapeutique*. Among the most interesting experiments are those made upon tuberculous animals and patients, the substance used being the serum of dogs and immunized animals. The dog serum is used because this animal is comparatively immune against tuberculous infection. Brancaro and Solaro treated four patients, using in one case about three ounces of serum altogether. But the results were negative. Professor Semmola recommends

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, November 11, 1893.

THE MODERN DIAGNOSIS AND TREATMENT OF DIPHTHERIA.

WHATEVER else sanitation has done it has not yet succeeded in checking the prevalence of diphtheria either in city or town. The disease is still the scourge of childhood, the dread of parents, and the reproach of medical art. For the recent practical application of bacteriology to the diagnosis of diphtheria has revealed in a very startling manner these two facts: First, that in over one-third of the cases the disease diagnosticated as diphtheria was not the genuine malady at all; second, that the mortality-rate of true diphtheria is between forty and sixty per cent. All the numberless contributions to diphtheria therapeutics which have been made so indus-

higher, and was difficult to feel from the diaphragm. a short space of time the abscess was freely laid open abdominal section without cutting into the peritoneu Drainage was established through the vagina and throu the abdominal incision, but the patient died of septicæm In both these cases there was a large encysted ascit tumor associated with suppuration in the peritoneal cavit

Ophthalmic Migraine.—The history of a case of op thalmic migraine in a man of forty is given by Evang lista, in the *Raccolitore*, May 10–20, 1893. Psychical Contagion in Schools.—Dr. Rembold, Stuttgart, describes a peculiar psychical outbreak. H was lately called to a school for girls in consequence one of the little pupils having fallen back, in an uncon scious state, on the form on which she was sitting—a incident which was followed in a few minutes by othe of the class fainting away, while others again broke o into crying and trembling fits, those who could articula complaining of feeling very ill. The alarm and co fusion arising from this strange occurrence spread to tl other classes, in one of which a girl thirteen years of a manifested the same nervous symptoms which had be already witnessed in the first class. On Dr. Rembol arrival he found among the forty little girls affected th ten were quite unconscious, seemingly sunk in profou slumber, a condition from which they could not aroused, even with violent shaking and when loud called upon by their names. Of those who retair consciousness he describes some as trembling all ov weeping and sobbing aloud, while others of them seen to be dazed and terror-stricken at the sudden illnes one of the most relentless of all caustics. Iodine is irritating when inhaled, as are the vapors from saturated solutions of chlorine. Solutions of carbolic acid are poisonous and inefficient as germicides. I have not succeeded with digestives." The action of corrosive sublimate is only inhibitory, not germicidal, and it is often futile. Dr. Williams finds in peroxide of hydrogen the most active, and at the same time least harmful, of germicides. This substance must be used, however, in strong solutions, *i.e.*, 25 or 50 volumes. The advantages of these are that they are good germicides and are not poisonous nor harmful to the mucous membrane; they cleanse a foul throat and break up and disintegrate certain portions of the diphtheritic membrane, thus rendering the bacilli more accessible. They likewise assist in diagnosis, for when the hydrogen peroxide, even in weak solution, is applied to the throat where there is any trace of membrane, it causes it to assume a white color from the presence of fine foam which is made by the liberation of the oxygen gas. It thus becomes a useful agent in detecting spots of membrane earlier than they would be apparent in any other way, and thus indicating the areas to which the treatment should be directed. With this end in view, the throat may be sprayed or the mucous membrane may be swabbed with dilute hydrogen peroxide. It is known that corrosive sublimate to a considerable extent is inhibitory rather than germicidal in its action, but it would be difficult to conceive of a merely inhibitory action on the part of hydrogen peroxide, as this substance is so readily decomposed.

No rule can be given for applying these solutions that will cover all cases. In a general way it may be said that the strong solutions of hydrogen peroxide containing about one-half per cent. of acid, made up chiefly of hydrochloric or sulphuric acid, should be gently but thoroughly applied every four hours during the night, and more frequently during the day for the first few days. The 25-volume solution may be used in spray; the 50-volume may be applied, a drop or two at a time, on a swab, until the membrane is removed or much diminished, or in certain cases the 50-volume solution may be applied with the syringe. Even a stronger solution than 50 volumes may be used for resistant membranes. It is well to use cocaine before applying the peroxide. By the help of bromide at night the patient loses very little sleep in being aroused for the local treatment. Every precaution should be taken to spare the patient's strength, and it is not necessary that the head should be raised from the pillow while the applications are being made.

There are some disadvantages to the peroxide treatment which are enumerated, and the limitations of it, and indeed of all local and late treatment, are dwelt upon. Still, by means of peroxide of hydrogen in strong solution, applied early and judiciously, it seems probable that the mortality-rate from true diphtheria may be reduced much below forty per cent. Of fifty-eight cases treated by Dr. Williams sixteen died, and among these the mortality was in some cases explained by incomplete or late application of the germicide.

The Thoughts of a Sad Man.—There are many bad physicians, and there are some who are better; but there are none who are very good. [Sometimes, too, there are very poor judges.—ED.]

IS THE GENERAL PRACTITIONER PASSING AWAY?

In one of the daily papers an old-fashioned lady, in speaking of times going by, is made to deplore the gradual extinction of the "family doctor." It may not be necessary to state that she was a resident of the city, that she spoke of the condition of things around her, and yielded with consistent reluctance to what she so sadly regarded as inevitable.

Her lament, especially as it pertains to the conditional requirements of large cities, is not without its ominous significance. As fashion crowds and the cultivation of distinct fields of practice becomes more and more necessitated by the desire to get fame and fortune with a minimum expenditure of energy, we may naturally fear that the general practitioner may after a while be left to do merely the odds and ends of practice, which remain after the apportionment of the already numerously appropriated special regions. It is comforting to know, however, that what is still good in general practice is not yet, in many cities and districts of country, entirely given over to the new order of things. In country districts more particularly, we still have the opportunity of studying the typical family physician, and preserving intact the admirable qualities which go to make up the well-rounded, broad-principled, general medical adviser. The country doctor so often unjustly patronized by his would-be metropolitan superiors, still maintains this useful position and triumphantly vindicates his right to pose as the recognized medical autocrat of the community in which he so laboriously, faithfully, and acceptably rules. While there are certain peculiarities of contact and environment which make such a relation necessary, we would not change it if we could. He is in his right place, he is performing excellent and satisfactory service, and in very many respects is in his doings an example worthy of emulation. And altogether, his experience in doors and out gives him that exercise of common sense which serves him as surely in podalic version as in the more complicated manœuvre of extricating himself from a snow drift on his way to the case. He broadens with the horizon of his drives, and has ample opportunities, between stretches, to hatch his live experiences in the quiet study under his buggy top. It is this forced introspection that prods the very marrow of his inner resources and makes him the trusted and self-reliant practitioner who can not only help himself but help others in seasons of trial and in times of emergency. There is certainly plenty of room for such men, and abundance of opportunities for them. The necessity for their being and doing we trust will never die out.

Certainly, in variety and extent of business he keeps himself in touch with all the refractory organs, and appreciates each one's position in the consistent whole that makes the general system the unit for attack. He learns that the darker the road, the greater the safety in giving the horse his head.

Thousands of such men are rattling over hill and dale throughout the country, and a goodly majority still maintain their hold on city business. A friend of ours very aptly replied to a question concerning his particular branch of practice, by stating that his specialty was confined to *visiting* patients when they were *sick*. He posed as a medical architect that knew the general plan of the built-up body, rather than the one who confined himself solely to adjustment of window lights, the boring of extra flues, the tinkering with ventilators, the altering of partitions, the trimming of alcoves, or the plumbing of new traps.

We do not mean to be understood that specialism is not necessary when special training is added to general experience, but we still maintain that the engineer who knows the connection of the drains can do more to the general good of the construction, than the more special man who sometimes undermines the constitution to demonstrate his pet system of sewerage, or weakens a thin partition for placing an oversized trap. Expert skill is always to be appreciated in its place, and it has too wide a range of usefulness to be gainsaid, but it is always a comfort to know that the general superintendent is not as yet extinct.

It is still proper that he should be encouraged in his general studies and numerous struggles, and be the rightful arbiter in the ever present war between the belly and the members.

FASHION AND NURSING.

One of the daily papers says that two or three years ago the Prince and Princess of Wales distributed badges and prizes to a large number of professional nurses, and afterward entertained them royally at Marlborough House. It was expected that fashionable dames would show their appreciation of the royal example by taking up nursing as a recreation, but little was done until a few months ago, when the National Health Society opened classes for the benefit of the aristocracy, at which something more is taught than a coquettish arrangement of caps and aprons. The idea is to teach ladies the value of good nursing, and enable them to learn something about fit food for invalids and how to give first assistance to the injured, in all of which, it seems, duchesses, countesses, and the like are lamentably deficient.

We fear that fashion has done almost too much for English nursing. Some specimens wander over to this country. They are usually well trained, but carry themselves with such a conspicuous air of self-restraint and such obtrusively repressed gentility, that it does not seem right to ask them to empty the urinal. Good breeding is an excellent and, indeed, indispensable thing for a nurse, but our English sisters seem to carry it on their sleeves like the other insignia of their office. So we say that perhaps fashion has made nursing too fashionable.

SERO-THERAPY.

The treatment of disease by means of injections of serum has been employed so extensively that the term serum-therapy is applied to it by Dr. Ed. Égasse in a critical review which appears in the *Bulletin général de la Thérapeutique*. Among the most interesting experiments are those made upon tuberculous animals and patients, the substance used being the serum of dogs and immunized animals. The dog serum is used because this animal is comparatively immune against tuberculous infection. Brancaro and Solaro treated four patients, using in one case about three ounces of serum altogether. But the results were negative. Professor Semmola recommends

these injections in connection with iodoform. Babes, of Bucharest, treated dogs with increasing quantities of human tubercular cultures, at first using old ones, then new. He finally succeeded in making dogs perfectly immune, and from these he asserts that he obtains a serum of great anti tubercular potency. This he demonstrated upon rabbits. Upon tuberculous men the injections produced "sensible amelioration," but he asserts that there has not yet been time enough to determine what the serum will actually do. Furthermore, he has attempted to produce the serum in large quantities by vaccinating cows. The milk of these animals, it is believed from experiments on other animals, will have antitubercular properties. Here is surely a practical field to work in. If the cow can only be turned into a curer instead of a spreader of tuberculosis, it will be an immense gain for humanity. We salute Herr Babes, and trust his fancy will not get ahead of his facts. Professor Bernheim has treated one hundred and five cases of phthisis by means of serum of immune animals, and he announces the same ancient tubercular formula, "with good results."

Professor P. L. Tommasoli has been treating lupus with dog serum; he has not had success as yet, but will try again with larger doses. A great deal has been said about serum-therapy in connection with tetanus. In 1870 Bering and Kitasato announced that the serum of animals rendered refractory to tetanus by trichloride of iodine, possessed preventive and curative properties against that disease. Tizzoni and Cattani studied the subject, and reached somewhat similar conclusions. Later they treated eight persons suffering from tetanus with serum from immunized dogs, and obtained eight cures. But soon after a disagreeable person, named Albertoni, announced that Tizzoni and Cattani did not report certain other cases which did not get well, also that the cured cases were of the chronic kind, that often get well spontaneously. Later still came reports of failures from Renon, Grancher, Polaillon, Auger, and Letulle; so that the serum therapy of tetanus was dead before it had time to know itself. However, last of all come Roux and Vaillard, who present a very complete monograph upon the subject. They conclude that when tetanus is once well developed, treatment is of little avail (among seven cases there were two cures). They believe, however, that the treatment is useful as a preventive, and may be of service at the beginning of the malady.

In regard to pneumonia, many experiments have been made, and great patience and ingenuity have been shown. It is demonstrated that one can confer immunity upon animals by injections of blood extracts and serum taken from those that are immune. Applying their experiences to man, Foa and Scabia have injected immunizing serum and extracts in ten cases of pneumonia, on the second, third, and sixth day after infection. In all, the crisis occurred on the second day after the injection; the patients recovered, but no definite conclusions were reached. Pausini reports successful experiments with animals, but gives no practical demonstrations on man.

Dr. Lava reports ten cases of pneumonia treated by serum therapy, with doubtful results. Bozzola reports five cases, with one death.

Dr. Audeoud has treated two cases of pneumonia successfully by injecting the blood of convalescents directly into the brachial veins of the patients. He cites a similar case reported by Dr. Hughes, of Philadelphia. The treatment is evidently still in an experimental stage.

CROSS-SADDLE RIDING FOR WOMEN.

The practice by women of riding the bicycle is steadily extending, and so far as we can learn is attended with no deleterious results. It has familiarized the public with the spectacle of seeing women riding astride, and doing it gracefully. The popularity of bicycle riding among women has made it more possible for women to accept the idea of riding *en cavalier;* an idea which is being put in actual practice in the West. In other words, cross-saddle riding with divided skirts has gained a certain amount of recognition in a number of localities. It has been found that ladies look well, ride more safely, and get better exercise in the new way. The practice of side-saddle riding is attributed to the vagary of a queen who was too deformed to use the cross-saddle. There has been a vague idea that any other method would, in young women, be disastrous by injuring the hymen. As a matter of fact, the practice of using the side-saddle has been adopted because it adapts itself to modern dress; and because without a special dress no other method would be suitable.

But cross-saddle riding is the safer way, it permits of a better and freer use of the limbs, and makes the exercise most effective. All this will not make women adopt it, however. A large number of lady riders take the exercise to avoid the unpleasant effects of too much fat. Side-saddle riding does not make fat women thin, however, but if anything enlarges the hips. Cross-saddle riding is more effective, because a wider range of muscles can be used, and harder riding indulged in. Let the *terque quaterque adipatæ* bear this in mind.

Booming Medicine.—The insane rush of young men, and women, too, into the profession is chiefly owing to the extravagant puffing of a considerable portion of its members regarding the financial results of their labor. I have a couple of physicians in mind, with whom I was familiar both as a youth and after entering the profession, whose careers are somewhat typical of the "booming" class. The one was the leading physician of a large town. He claimed and was generally accredited with doing a practice of $25,000 a year. He lived quite inexpensively, except in the matter of horses, several of which he always kept to encourage business, and after struggling with a practice of this kind for twenty-eight years, he suddenly collapsed, leaving his creditors in for over $20,000. The other practised in a small village, and for years had done a tremendous practice; kept half a dozen horses, slept little, and had rarely time to take his meals; he lived quite inexpensively, except in the matter of horses; he took but one holiday during his whole career; and he affected, and was generally supposed to be possessed of, fabulous wealth; and after a laborious professional life of forty years, departed, leaving an estate valued at less than $5,000. I can name a score of men in the profession to-day, who have been lured there by the boasting of these two. This unmanly habit afflicts the profession to a disgraceful extent, and does it more injury than any other affliction to which it is subjected.—*Dr. J. P. Armour, in Medical News.*

News of the Week.

The Late Dr. Charles Slover Allen.—The Society of the Alumni of Charity Hospital heard with sincere sorrow of the death of their associate, Dr. Charles Slover Allen, and at the last stated meeting of the Society the following preamble and resolutions were adopted:

Whereas, In the death of Dr. Allen we lose a valued and esteemed associate and friend; a faithful student and accomplished member of our profession; and

Whereas, We acknowledge his friendly interest and the stimulus of his high ideals in our profession, and as a gentleman. It is, therefore,

Resolved, That we express our sincere and heartfelt sorrow at his death. And further, it is

Resolved, That we tender to his bereaved family our profound sympathy. And further, it is

Resolved, That a copy of these resolutions be sent to the bereaved family, to the medical journals, and spread upon the minutes of the Society.

A. T. Mussy, M.D.,
Ralph Waldo, M.D.,
Daniel P. Pease, M.D.

The Late Dr. Alfred Ludlow Carroll.—The members of the Council of the New York State Medical Association deeply mourn the loss of their beloved, erudite, scholarly, and gentle colleague, Alfred Ludlow Carroll, M.D., who has labored so well and so assiduously for the Association, for the profession, and for the people, as the editor of the Association's "Transactions," as a prolific contributor of scientific material, as a promoter of the honor, dignity, and advancement of medical science, and as one of the foremost sanitarians in the land. The Council has therefore resolved that their high appreciation of the noble qualities and of the scientific accomplishments of their late gifted and lamented colleague be recorded in this volume of "Transactions," and in the medical journals, and that a copy of the above be transmitted to the family of the deceased.

E. D. Ferguson, M.D., Secretary. Done by the Council, November 4, 1893.

The Southern Surgical and Gynecological Association.—The sixth annual meeting will be held in the Assembly Room of the Medical Department of Tulane University, New Orleans, La., on November 14, 15, and 16, 1893.

Dr. Joseph Collins has been appointed Attending Physician to St. Mark's Hospital, New York.

Congress of American Physicians and Surgeons.—A meeting of the Executive Committee of the Congress of American Physicians and Surgeons was recently held at the house of the Chairman, Dr. Landon Carter Gray. A local committee of arrangements in Washington was appointed, as follows: Dr. S. S. Adams, Chairman, representing the Pediatric Association; Dr. John S. Billings, the Surgical Association; Dr. H. G. Beyer, the Physiological Association; Dr. S. O. Ritchie, the Otological Association; Dr. S. C. Busey, the Gynecological Association; Dr. W. W. Johnson, the Climatological Association; Dr. J. Atkinson (Baltimore), the Dermatological Association; Dr. William H. Welch (Baltimore), the Association of Physicians; Dr. I. C. Rosse, the Neurological Association; Dr. Samuel Theobald, the Ophthalmological Association; Dr. T. Morris Murray, the Laryngological Association; Dr. D. W. Prentiss, the Genito urinary Association; Dr. Frank Baker, the Anatomical Association. It was arranged that the following subjects should be discussed by the Congress at its next meeting in Washington, in the latter part of May, 1894: The Climatological Association, "Sewer Gas;" Genito urinary Association, "The Surgical Kidney in its Clinical Aspects;" Dermatological Association, "Leprosy in the United States;" Laryngological Association, "Intra-nasal Surgery;" Gynecological Association, "The Conservative Treatment of the Female Pelvic Organs;" Neurological Association, "The Effects of Infectious Processes on the Nervous System." One association is yet to select a subject for discussion. Dr. W. H. Carmalt, of New Haven, Conn., resigned from the sub committee deputed to take charge of the organization of the Congress, and Dr. William H. Welch, of Baltimore, was appointed in his place; so that the committee now consists of Dr. A. L. Loomis, President of the Congress, Dr. Landon Carter Gray, Chairman of the Executive Committee, Dr. Newton M. Shaffer, Secretary of the Executive Committee, and Dr. William H. Welch.

College of Physicians and Surgeons, Richmond, Va.—Dr. John F. Wynn has been elected Professor of Diseases of the Nervous System in this new college.

Death of Dr. H. D. Lachenour, of Easton, Pa.—Dr. Henry D. Lachenour died in Easton, Pa., of apoplexy, November 6th. He was fifty-five years old. Mrs. Lachenour had been at death's door for over a week from heart troubles, and Dr. Lachenour devoted his entire time to her. To his constant attendance and care was due the saving of her life. She showed decided improvement Sunday, and yesterday Dr. Lachenour expressed his gratification to his associate physician, and then lay down on a couch to rest. Two hours later he was dead.

The Death of Dr. W. S. Holbrook.—Dr. W. Stephen Holbrook, died November 5th, in Newark, at the age of thirty.

London has a society of anæsthetists.

No Further Fear of Cholera.—The Treasury Department has semi-officially declared that there was no further fear of cholera being introduced from Europe by immigrants in deciding to recall nearly all the surgeons of the Marine Hospital Service now stationed at the principal European ports. This decision was reached after a conference between Assistant Secretary Curtis and Dr. Wyman, chief of the Marine Hospital Service.

The Superintendents of the New York State Hospitals for the Insane met with the State Commissioners in Lunacy, October 26th. A resolution was adopted providing for the appointment of a committee of three for each quarter of the year, whose duty it shall be to confer and agree on qualities, prices, etc., and obtain proposals from established houses. Superintendents Talcott, Pilgrin, and Wagner were named as the first committee, and are empowered to act until April 1st next. It was voted that the Superintendents frame some plan to make the salaries and wages paid hospital employees more uniform. The commission thinks that some action in this regard has become imperatively necessary. It was decided that the commission appoint a pathologist of recognized

reputation and qualifications, with headquarters in New York City, the expense to be borne by equal monthly payments from the funds of the several State hospitals. A resolution was adopted providing that, in view of the prevalence of small-pox in cities, a general vaccination of the inmates of State hospitals be made.

Dr. Robert Battey, of Rome, Ga., has presented his medical library to the State of Georgia upon the condition that it be placed in a separate alcove in the State Library at the State Capitol as a nucleus of a State Medical Library.

La Grippe is reported to be virulently epidemic in Alaska.

Dr. William H. Galt, one of Louisville's most prominent physicians, died on October 14th, aged sixty-seven. Dr. Galt was at one time one of the editors of the *Louisville Medical News*, and held the chair of Theory and Practice of Medicine in the Louisville Medical College. He was also Health Officer of Louisville for a number of years.

Death of Dr. Clarence Glisan, of Portland, Ore.—The following resolutions were adopted at the last meeting of the Society of the Alumni of Bellevue Hospital:

Resolved, That it is with the deepest regret that this Society has learned of the death of Dr. Clarence Glisan, one of its younger members, who had entered upon a career of honor, usefulness, and success.

Resolved, That in the death of Dr. Glisan his colleagues have lost a friend endeared to them by his noble qualities of heart and mind.

Resolved, That this Society, in expressing its sorrow and appreciation of its loss, desires, in addition, to extend its deep sympathy to his bereaved family.

(Signed) STUART DOUGLAS, M.D.,
D. H. MCALPIN, M.D.,
W. E. STUDDIFORD, M.D.,
Committee.

Obituary.

SIR ANDREW CLARK, M.D.,

LONDON, ENGLAND.

OUR later despatches from London, which appear in the letters of our London Correspondent, and to which our readers are referred in another part of the RECORD, have prepared us for the cable despatches announcing the death of Sir Andrew Clark, of London.

The apoplectic attack with which he was seized some days ago was the beginning of the end. Death occurred November 6th, at the age of sixty-six. Sir Andrew was born on October 28, 1826, and was educated first at Aberdeen and then at Edinburgh, in whose medical schools he took the first medals in anatomy, physiology, chemistry, botany, materia medica, surgery, pathology, and practice of medicine. After assisting Dr. Hughes Bennett for two years in the pathological department of the Royal Infirmary, and acting as demonstrator of anatomy to Dr. Robert Knox, the famous anatomist, he had charge for the following four years of the pathological department of the Royal Naval Hospital at Haslar, where he delivered lectures on the use of the microscope in practical medicine. Dr. Clark took his degree of M.D. from the University of Aberdeen in 1854, after which he went to London, where he became a member of the College of Physicians and Surgeons, and was elected on the staff of the London Hospital. He was made a fellow of the Royal College of Physicians in 1858, and was subsequently its President, and President of the Medical Society of London, and lastly of the College of Physicians, which position he held at the time of his death. He was made a baronet in 1883, and nearly all the honors and titles of the medical profession were his. He was a fellow of the Royal Society, a Doctor of Laws of Cambridge, Edinburgh, and Aberdeen, an honorary fellow of the King and Queen's College of Physicians in Ireland, etc. His works on the different departments of internal medicine are numerous, and are authorities on the subjects of which they treat. Dr. Clark was also renowned as a lecturer on his specialties. The lesson of his life is one which can be taken to heart by every struggling practitioner. In his early career his health was so poor that he was allowed to take his first position in a London hospital not only as an acknowledged reward of merit, but on the assumption that he could not be able to hold it long, and that his death would soon leave it vacant for the next on the list. But by husbanding his resources and by untiring energy in his work he long outlived his competitors and made himself the most famous medical man in England.

Reviews and Notices of Books.

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS, with Especial Reference to the Clinical Application of Drugs. By JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics, and Clinical Medicine, and Clinical Professor of Diseases of the Skin in the Medico Chirurgical College of Philadelphia; Physician to the Medico-Chirurgical Hospital, Member of the American Medical Association of the Pennsylvania and Minnesota State Medical Societies, the American Academy of Medicine, the British Medical Association; Fellow of the Medical Society of London, etc. Second Edition, thoroughly revised, in two volumes. Philadelphia and London: The F. A. Davis Co. 1893.

WE are glad to welcome the second edition of Dr. Shoemaker's practical work on therapeutics, for however numerous books of this class may be there are never too many of them. This field is a wide one, and no man can ever expect to cultivate it exclusively or to cover it thoroughly. Each author contributes something to the general fund of the science of curing disease, the most important part of medicine, which others have omitted, and none, who is not a mere compiler, can fail to bring forward something of practical value. The first volume of this treatise is devoted to a consideration of pharmacy, general pharmacology and therapeutics, and the remedial agents not properly classed with drugs, while the second and larger volume treats exclusively of drugs. Many changes and additions have been made in the second edition of this volume, as would be expected in view of the constant accretion to our stock of drugs, not only those of the coal-tar series but those derived from the vegetable kingdom as well. We should have been glad to see a rather fuller account of serum therapy and of the employment of animal extracts, although, of course, the time is not yet ripe for any definite conclusions to be formulated concerning the real value of this new means of combating special diseases. The book would have been made more useful to the present generation of students had the doses of the various drugs been given according to the metric system as well as in apothecaries' weight. The indexes are very full, and, as far as we have been able to compare them, accurate, but a table of contents to the second volume would have been a convenience to one wishing to study the work systematically.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON GENERAL MEDICINE.

Stated Meeting, October 17, 1893.

CHARLES E. QUIMBY, M.D., CHAIRMAN.

Albuminuria without Renal Disease.—DR. W. B. VANDERPOOL read this paper. (See page 611.)

Uncomplicated Albuminuria not Dangerous.—DR. ALFRED L. LOOMIS opened the discussion. He thought the paper presented so complete a *résumé* of our knowledge of albuminuria without renal disease that little remained to be said. He would divide these cases into three classes: 1. Those that were best designated functional albuminuria. 2. Those in which there was an excess of excrementitious substances, which the kidneys must eliminate. 3. Those depending mainly upon some disturbance of the venous circulation. In functional albuminuria we were justified in giving a good prognosis. He spoke of the second class of cases as constituting the irritative form of albuminuria, and said this was apt to be attended early by disturbance of the heart and an interference with the nutrition of the vessels. He had long thought that examiners for life insurance made a mistake in rejecting a certain proportion of cases of supposed heart disease when a murmur was the only indication of such disease. And he felt the same with regard to albuminuria. There were, of course, a good many other facts to be taken into consideration in determining the exact importance of albumin in the urine. Allusion had been made to the specific gravity of the urine, but it seemed to him more stress might be laid upon that point. If, under ordinary conditions of life, the urine collected for the twenty-four hours retained a specific gravity of about 1.020, the presence of albumin would have less significance than if the specific gravity was above 1.026 or below 1.014. Again, if the subject were forty-five years of age or older, the albuminuria would have greater significance than if he were younger, for the reason that after forty-five cardiac and vascular changes were likely to occur. Independent of age, the general condition of the patient must be taken into account. Sometimes a patient was found to have albumin in the urine, whose heart-action was feeble and irregular, and yet there was no apparent lesion of the heart, the weak circulation being due, perhaps, to a neurotic state, or failing nutritive changes in the cardiac muscle which render it liable, on violent exercise, to sudden dilatation. If in such a case regulation of the diet and exercise, and the administration of cardiac tonics, caused the albumin to disappear, we conclude that its presence has been due simply to feeble heart action, allowing passive venous obstruction in the kidneys. Of course, if this condition becomes persistent, renal changes will take place.

The irritative form of albuminuria seemed to the speaker to be the most significant, if it were attended by a pulse of high tension and urine of high specific gravity, conditions which pointed with some certainty to beginning fibroid changes in the arterial system. In such patients a gouty, lithæmic, or other abnormal condition was likely to attract attention in addition to the albuminuria. Very much could be done to cause disappearance of the albumin temporarily, yet when such patients reached the age of sixty or sixty-five they were likely even to present other evidences of interstitial nephritis.

Although some claim that the kidneys cannot excrete albumin long without showing evidences of nephritis, yet Dr. Loomis doubted very much if the mere presence of albumin in the urine in a case of functional albuminuria would excite a nephritis. If nephritis should follow such a condition there were many possible causes which must be excluded before accepting the statement that it was due to the presence of albumin in the urine.

How Albumin Gets into the Urine.—DR. W. H. PORTER expressed some views upon how albumin got into the urine. He thought albumin would not filtrate through the blood-vessels unless these were in a pathological state. The greater the amount of albumin in the urine, the greater the change in the vessels or their epithelium. He was disposed to regard albumin as a by-product of oxygenation which was drained off, when in excess, by the renal cells. This seemed to him to be a pathological condition. But if the amount of urea, uric acid, lactic acid, or glucose in the urine were normal, he would agree with Dr. Loomis that little harm was likely to occur unless the albuminuria remained constant for a long time; in this event it might result in overtaxing the renal cells and cause a lesion. If there were also excess of uric acid, oxalic acid, lactic acid, and glucose, it would point to a retrograde change in the renal cells and a bad prognosis. In the first variety, regulating the diet and habits of the patient would be sufficient to render the prognosis favorable. High specific gravity of the urine indicated to him incomplete oxygenation all the way from the stomach to the kidney, and with this condition albuminuria gave an unfavorable prognosis.

DR. R. C. M. PAGE agreed with the opinions already expressed, that temporary albuminuria in slight degree often existed without renal lesion. Moreover, temporary albuminuria might occur in connection with a number of diseases. During the late epidemic of grippe, several of his patients had temporary albuminuria, one in so high a degree that for a time he felt grave apprehension regarding the condition of his kidneys. In all of these cases the nervous prostration and mental disturbance were marked features of the attack of grippe. But in all the albumin disappeared and had not returned. Albuminuria was sometimes seen in dyspepsia, especially those forms of dyspepsia which were accompanied by a great deal of nervous prostration, and he thought the nervous element probably had something to do with causing the appearance of the albumin in the urine. Perhaps there was vaso-motor disturbance, causing leakage through the renal capillaries. Thus, the presence of albumin in the urine was no positive proof of disease of the kidneys, and in all cases there should be microscopic examination of the urine. If casts were found, the prognosis became grave. It was also grave even without casts, if the amount of albumin were large, and especially if the patient showed a tendency to dropsy. As to treatment, let it be dietetic and directed against the exciting factors.

A Case of Marked Functional Albuminuria of Long Standing.—DR. GEORGE B. FOWLER thought the medical profession to-day was fully cognizant of the fact that there were various kinds of albuminuria, some of pathological import, others not. He had thought he was acquainted with all forms until 1888, when he came to examine the urine of a man whom he had known from boyhood, and was astonished to find that it contained much albumin. No cause could be discovered. The specific gravity of the urine ranged from 1.020 to 1.024; it contained no casts. The man's health was good, and yet the albumin in the urine persisted in spite of all possible regulations with regard to diet, administering of heart tonics, etc. Finally, the consultant recommended the granting of a life insurance policy in spite of the large amount of albumin in the urine.

Should Nitrogenous Food be permitted in Renal Disease?—The Chairman, DR. QUIMBY, inquired whether it was permissible under certain conditions, at least, to permit patients with renal disease to partake of a nitrogenous diet; or should they be limited to carbo-hydrates. The question was suggested by a case in which he was reprimanded by an able member of the profession for allowing the patient albuminous food.

Avoid an Excess.—DR. FOWLER thought the matter of diet in renal disease might be carried too far. A little common sense would answer the question. Diseased kidneys must excrete a little albuminous matter as well as healthy ones, and what was required for the patient's health was a proper amount of carbo-hydrates, of fats, and of albuminoids, not an excess of any one of these elements. There was likely to be heart-disease in these

cases, with derangement of digestion, and vegetable foods, or starches and sugars, were even more likely to ferment and cause trouble than albuminous elements. Moreover, vegetables were not free from albuminous matter.

Dr. Louis Waldstein had seen a great many cases of albuminuria, and had found that one could not judge of the gravity of the condition without long observation of each patient. He was unable to say whether any one of his cases had passed into organic lesions of the kidneys. In all there had been an increase in the amount of urea—the normal being about two per cent., this quantity was doubled. He had also been impressed by the increase of phosphates and specific gravity. He had been led to think that the condition was an expression of increased metabolism, rather than of suboxidation. Most of the subjects were overworked, mentally if not physically. Many were not great eaters, and many had dieted to excess on the supposition that the food was the cause. They were business men, with much work and worry, who awoke in the morning even more languid than when they had retired. When he had insisted upon rest the albumin disappeared, the specific gravity of the urine fell, the amount of urates became less. A change of diet without rest had been of little benefit.

Dr. W. H. Porter said, with regard to diet, that to him the problem was a very simple one. The lungs were capable of conveying into the blood a certain amount of oxygen in the twenty-four hours, about 750 grammes; with that a certain amount of food could be oxygenated, and if more were taken it would be waste, and cause the system, especially the weak organs, to be overtaxed in getting rid of it. The system called for about a given amount of albuminoids, of sugars, starches, and fats, and when the right proportions were observed it was carried on most easily. Starting with this data, it was yet to be borne in mind that animal food was more readily utilized than vegetable food. If an anæmic person should take 640 grammes of food in the twenty-four hours, composed of 7 ounces of bread, 14 ounces of meat, 2 eggs, and the rest milk, he would still have a margin of over 100 grammes of oxygen, and could live on such a diet without exceeding his oxygenating capacity. His experience had been that a diet based on these principles would soon cause the urine to return to normal.

Dr. Vanderpool said that in organic kidney disease his experience had led him to favor a mixed diet, and he thought it would be best also in functional albuminuria. The old rule, to place the patient upon a milk diet, led to digestive disturbances.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Nineteenth Annual Meeting, Held at Indianapolis, Ind., October 4, 5, and 6, 1893.

First Day, Wednesday, October 4th.

The Association met in Plymouth Church, and was called to order by the Chairman of the Committee of Arrangements, Dr. George J. Cook, of Indianapolis. Divine blessing was invoked by the Rev. Frederick E. Dewhurst. Governor Matthews was introduced and delivered an Address of Welcome.

Fibroid Tumors of the Uterus.—The President, Dr. R. Stansbury Sutton, of Pittsburg, was introduced, and delivered the President's address. He selected for his subject "Fibroid Tumors of the Uterus." After giving a definition of these tumors, the author dwelt upon their etiology, which he said is still a mystery. They are more frequent in the black than in the white race. In both races they are more frequent in the body than in the neck of the uterus, and more frequently situated in the posterior than in the anterior wall. After the menopause is established these tumors generally disappear, unless they have undergone cystic degeneration. Bearing on this point, Dr. Sutton reported an anomalous case. The patient was forty-three years of age, she had never menstruated in her life, had never shown any physiological evidence of ovulation, had been twice married, was then a widow and childless. She had for ten years a large fibromyoma of the uterus, which thus far gave no evidence of atrophy.

With regard to the pathology, the tumor always has its origin in the substance of the uterine wall, or subperitoneal connective tissue. The symptoms accompanying the presence of these tumors, in various localities and stages of growth, are widely different. However, the class of indications are patent as found in the vast majority of cases, and may be tabulated as follows: 1, vague pain in the pelvic region; 2, pain referred to the front or back of the leg; 3, irritability of the bladder or rectum; 4, uterine tenesmus; 5, menorrhagia or metrorrhagia; 6, dysmenorrhœa; 7, profuse leucorrhœa; 8, serous discharge from the uterus.

The diagnosis of very small fibromyomata, when many of the leading symptoms are absent, is considered extremely difficult. As far as the medical treatment is concerned, but little can be done for the relief of patients suffering from fibromyomata, and nothing for those suffering from those tumors which have undergone cystic degeneration. Surgically, there are but two routes by which solid uterine tumors can be removed—either through the vagina or by abdominal section. With the exception of small tumors with a well-defined pedicle, all subperitoneal fibromyomata are reached only by section of the abdominal wall. Dr. Sutton in one case divided the posterior wall of the vagina, and through this opening delivered the tumor.

SECTION ON GENERAL MEDICINE.

Dr. O. Everts, of College Hill, O., Chairman.

Forensic Medicine.—This paper was read by Dr. C. G. Comegys, of Cincinnati. The author had come to the conclusion, from his experience, that there are but few lawyers sufficiently informed in medical science to conduct a case in the interests of truth and justice, especially the most important cases in medical jurisprudence. Every physician, as an expert witness, must have observed the embarrassment of lawyers in trying medical cases. They ask questions enough, but from their lack of medical experience they are incapable of thoroughly understanding the answers of a witness, so that the proper interpretation of them bearing upon the history of a case at the bar may be reached, and when endeavoring to give the court and jury clear views of the subject by additional questions, they often confuse the whole investigation. This disagreeable state of affairs is usually brought about by certain lawyers who have armed themselves by a superficial study of medical works for the occasion. Dr. Comegys believes that the high order of legal men will welcome well-trained men in medicine as coadjutators in medicine in the lofty work of establishing justice.

Problems of Public Interest Concerning the Insane.—By Dr. Orpheus Everts, of College Hill, O. The author said there are several problems of public interest involved in the present relations of society to the insane. Among the more important of these are questions of dependency and curability of the insane, and the preventability of insanity. The author summarized his conclusions as follows:

1. Intelligent provision for the insane implies provision for various classes, according to the capabilities of enjoyment and the exercise of variously impaired faculties.

2. Public provision for whatever class of insane persons implies housing, clothing, food, sanitary and moral discipline, amusement and employment for such as are capable of being amused and employed, and medical treatment for the sick. The essential features of such provision are adaptability to the needs of each distinctive class.

3. Great, expensive, architecturally imposing palaces, providing alike for all classes, however serviceable they may have been, æsthetically considered, in time past, as they unquestionably were, are no longer necessary nor

appropriate to the needs indicated. So long as the insane are comfortably housed, each class according to its condition, it is comparatively unimportant whether it be in large or small houses, cottages or palaces, connected or detached, in high or low buildings.

4. It is important that the insane of all classes be well fed, under careful supervision; but whether in small or large dining-rooms, by groups or congregations, is of little consequence; that it should be a matter of convenience rather than of number.

5. It is important that public institutions for the insane be well organized and administered.

6. It is wise to retain in office capable men, who have demonstrated their fitness by successful management of affairs, so long as their capabilities continue to be elastic.

Chorea in its Relation to Rheumatism.—This paper was contributed by Dr. I. N. Love, of St. Louis. The author said that recently the pathology of this disease has been cleared up to a very considerable degree, so that now it is a definite affection, and one especially incident to childhood. Dr. Love reported a case of chorea occurring in his practice with a marked history of rheumatism, it being one of ten cases observed and illustrative of this class. The cases did not occur successively. Between them other cases presented themselves minus the rheumatic history, but four of the number occurred in rapid succession with a pronounced rheumatic history. Of the entire ten, seven were girls.

Among the exciting causes of the disease are irritation in the nostrils and adenoid growths in the vault of the pharynx. Inasmuch as Kirkes, Tuckwell, Hughlings Jackson, and Bastian support the embolic theory of the disease, and in consideration of the fact that chorea is so frequently associated with endocarditis, we should be on the alert to interrogate the heart when called to a case of chorea. As matters now stand, we have numerous exciting causes resulting in chorea.

Chorea: its Pathology and Treatment.—This paper was contributed by Dr. H. M. Lash, of Indianapolis. So much uncertainty has existed regarding the pathology of chorea that [illegible] and rapid [illegible] the above treatment. But, as a rule, if the case has been neglected until pelvic peritonitis has occurred, with its tendency to adhesions and recurrence, we will save many years of suffering, if not life itself, by advising removal of the appendages after a sufficient trial has been given to conservative treatment.

Frequently, in the puerperal state we have a pelvic peritonitis arise without affecting the tubes, the inflammation spreading directly through the uterus; there is an exudate formed which rest and proper treatment will absorb and leave the appendages healthy, so that later pregnancy takes place and the patient goes on to full term. In these cases, if suppuration occurs, laparotomy should be advised. In tubercular salpingitis the question of removal will depend wholly upon the amount of general systemic infection. The author believes that nearly all suppurative diseases of the tubes and ovaries are due to gonorrhœa, his experience leading to this belief.

The author closed with a few words on the value of electricity in the treatment of inflammations of the uterus and appendages. He values this very highly, and in the catarrhal forms of endometritis in young girls and primiparæ, we can obtain a cure if sufficient time is given. He applies the positive pole intra uterine, and the negative in the form of a broad electrode over the whole abdominal region, using a current strength of from twenty to fifty milliampères for five minutes, every third day. It requires from fifteen to twenty applications to complete a cure.

[illegible] cause of its singularity, in being more treacherous and insidious in its manifestations than any other affection that is met with by the practitioner of medicine.

The uncertainty of diagnosis had caused some excellent practitioners to adopt the pernicious habit of diagnosticating and treating all cases of sore throat, whether simple or malignant, as if they were true diphtheria. True, the treatment designed for a diphtheria may cure a tonsillitis, but inestimable harm may have been done in causing an unnecessary alarm on the part of the patient's family, and the disagreeable inconvenience that accompanies isolation of the patient and quarantining of the family, to be followed by the mockery of disinfection of non-infected apartments, and perhaps destruction of clothing and furniture. On the other hand, a case of diphtheria, diagnosed as a simple tonsillitis, may be the cause of breaking up a school or producing an epidemic, with an indefinite amount of sickness and many deaths. A case was cited in point.

Dr. Culbertson then referred to the importance of utilizing the science of bacteriology, and mentioned the plan adopted by the New York City Board of Health, of having undertaken to provide laboratory facilities for all practitioners of medicine in that city free of charge.

A Treatment Giving a Low Death-rate in Cases of Diphtheria in Hospital and Private Practice.—Dr. William A. Galloway, of Xenia, O., read this paper. The subject was treated from the standpoint of recent hospital practice, two hundred and thirty-four cases with a death-rate of fourteen per cent., under favorable sanitary surroundings. The paper embraced reports from private practice of physicians who had given the treatment faithful trial during the past three years, who unhesitatingly commended its value, and all were able to show a death-rate below ten per cent. The subject was divided into the hygienic, in which the most careful attention was paid to the isolation and surroundings of patients; the constitutional, and local topical treatment, the latter being considered by the writer as secondary in importance. Under constitutional treatment, immediately the nature of the disease was suspected, the writer gave one grain of calomel for each year of the patient's age up to eighteen, repeating the dose in four to six hours, and met the action of the mercurial with copious hot water injections. This treatment was persisted in until the full action of the calomel on the liver and kidneys was obtained, relieving these two important excretory organs of the paretic condition caused by the absorption of the toxalbumin product of the Klebs Löffler bacillus. Improvement in the patient's appearance was immediate, and the mercurial acted freely. The quantity of foul-smelling grass-green dejecta resulting is astounding. There is no fear from salivation, as under the most heroic use of mercurials no symptom of salivation has been observed by the writer or his friends. Internally, corrosive sublimate was given up to one-eighteenth of a grain, with full doses of tincture of chloride of iron, and alcohol, hourly at night and during the day. Local topical treatment consisted of peroxide of hydrogen, one-quarter solution, for cleansing the throat, which was commended, while as an escharotic twelve grains of salicylic acid to one drachm of alcohol were used twice a day by the physician only. It proved of great value in the writer's hands. This escharotic is very powerful, and should be used carefully if needed.

The Study of a Fatal Case of Essential Tachycardia.—This paper was contributed by Dr. John C. Sexton, of Rushville, Ind., in which he detailed the symptoms and clinical features of a case of essential tachycardia that died after thirty-five days' illness. The attractive feature of the case was the response to manipulative efforts, electrical and other, by the doctor, to produce stimulation of the pneumogastric nerve and thus to slow the heart. The paper then reviewed the ordinary symptoms of heart hurry as presented in the literature of the subject, and some further remarks concerning the causation, symptomatology, and treatment.

Papers were also read by Drs. R. E. Haughton, of Midland, Tex.; A. Ravogli, of Cincinnati, and others.

General Medicine.—The address on general medicine was delivered by Dr. James F. Hibberd, of Richmond, Ind. His conclusions were: 1. That there is a rapid progress being made in preventive medicine. 2. That our present conception of the complicated organization of the human body is based on the theory that the Creator in the beginning endowed vitalized matter with a perpetual law of virtue, of which man has been developed,

step by step, from primitive protoplasm. 3. That there is no longer dubiety in the proposition that the cell is the unit of vital activity, and that all living beings are a single cell or an organization of cells and cell products. 4. That the influence of the mind on vital activities, normal and abnormal, is not recognized as it should be, and that there is a line of study that would, if properly pursued, dissolve the agnosticism that has in the past embarrassed a knowledge of the reciprocal relations of matter and mind

---

SECTION ON OBSTETRICS, GYNECOLOGY, AND ABDOMINAL SURGERY

DR. ARTHUR W. JOHNSTONE, of CINCINNATI, CHAIRMAN.

Ovariotomy in the Aged.—The first paper in this section was read by DR. RUFUS B. HALL, of Cincinnati. The author confined his remarks to patients who were seventy or more years of age. He said it was generally conceded as true that any operation upon the old did not promise as good results as the same operation would upon the young or patients in middle life. Especially was this true in reference to all abdominal operations necessitating a hard strain upon the system from shock, or from traumatism to vital organs during the operation, as we not infrequently have in the removal of large ovarian tumors. Dr. Hall maintains that the death-rate is not greater than that which usually follows the same delayed class of operations on women between forty and fifty years of age. He had had but three ovariotomies upon women above seventy years of age. In each of the first two cases the friends of the patients hesitated to have the operation made on account of the advanced age of the patients. In each of these the operation was deferred until the patient was *in extremis*.

Dr. Hall then detailed three interesting cases of ovariotomy performed on patients, aged respectively seventy, seventy years and six months, and seventy-two years. Judging from the low mortality of the reported cases and from the work of the best known operators, the author is constrained to believe that ovariotomy in old women, if the kidneys are healthy, is as safe as in middle life.

The Value of a Close Observation of other Men's Work.—This paper was read by DR. WILLIAM H. LINK, of Petersburg, Ind. He said it is by the tireless energy of originality, and the endless application of original methods to both the expected and the unexpected in surgery, that has thus far pushed our work and its underlying science toward perfection. By close and frequent observation, defects in technique and improper application of surgical measures may be noted, and, having been recognized, may be avoided. There is no field in which object-lesson teaching is so effective, so fruitful of valuable practical results as in gynecological surgery. The observer may not always know whether the operation he witnesses carries the patient on to recovery or the contrary; but, if a close observer, he is improving his own surgical judgment. He is studying, rejecting, or adopting methods and aphorisms as they impress his intelligence or his reason approves. By seeing work done under varying conditions and with different results, we readily come to the conclusion that a private hospital is by no means necessary to successful work; that the pure air of a country or village home, or a clean room in a private residence in a city, is as good a place for surgical work as the most painted and gilded hospital, and that no one need hesitate because his patient cannot have the supposed advantages of some place especially set apart for the sick.

Intestinal Obstruction Following Abdominal Section.—DR. L. H. DUNNING, of Indianapolis, Ind., read a paper with this title. Of the complications following abdominal section, few are more fatal than occlusion of the intestines. It may appear in a few hours after the section, or not until several weeks have elapsed. In this paper the author dealt only with acute intestinal obstruction. The author is conscious of having met with but a single case in one hundred and thirty abdominal sections, yet this case occurred two and a half weeks after what he had considered a very successful ovariotomy.

The question of the administration of cathartics in cases of suspected or threatened occlusion of the intestines, is one oftentimes most difficult to decide. Under such circumstances he is inclined to the belief that during the first week after section cathartics are indicated, and he prefers to administer one-grain doses of calomel every hour for a few times, then administer two-drachm doses of Epsom salts every two hours, until an action is obtained, or it is demonstrated that a harmful effect is being produced.

A distinct understanding of the pathological conditions possibly present, must guide the operator in his search for the cause of the occlusion, and when found it should be dealt with in the shortest possible time consistent with the permanent cure of the patient.

The Present Status of the Treatment of Uterine Fibroids.—This paper was contributed by DR. XAVIER O. WERDER, of Pittsburg, and in the absence of the author was read by DR. THOMAS B. EASTMAN, of Indianapolis. For the sake of convenience, the author divided the treatment into the symptomatic and the radical, and confined himself to those views which seem to be generally accepted by the leading and unbiassed authorities of the present day. The principal symptoms produced by uterine fibroids requiring our attention are hemorrhage and pain. Hemorrhage is one of the most constant and dangerous complications, and is due to a diseased and hypertrophied condition of the uterine mucosa and hyperplasia of its blood-vessels (Wyder), or, according to the later researches of Semb, to an hypertrophy of the uterine muscles accompanying the growth of the myoma, with a simultaneous hyperplasia of the blood-vessels. The operations practised for the radical cure of myomatous growths are vaginal enucleation, removal of the appendages, enucleation by laparotomy, and supra-pubic hysterectomy. The author then considered these operations at length.

[illegible] important cases in medical jurisprudence. Every physician, as an expert witness, must have observed the embarrassment of lawyers in trying medical cases. They ask questions enough, but from their lack of medical experience they are incapable of thoroughly understanding the answers of a witness, so that the proper interpretation of them bearing upon the history of a case at bar may be reached, and when endeavoring to give the court and jury clear views of the subject by additional questions, they often confuse the whole investigation. This disagreeable state of affairs is usually brought about by certain lawyers who have armed themselves by a superficial study of medical works for the occasion. Dr. Comegys believes that the high order of legal men will welcome well-trained men in medicine as coadjutators in medicine in the lofty work of establishing justice.

Problems of Public Interest Concerning the Insane.—By DR. ORPHEUS EVERTS, of College Hill, O. The author said there are several problems of public interest involved in the present relations of society to the insane. Among the more important of these are questions of dependency and curability of the insane, and the preventability of insanity. The author summarized his conclusions as follows:

1. Intelligent provision for the insane implies provision for various classes, according to the capabilities of enjoyment and the exercise of variously impaired faculties.

2. Public provision for whatever class of insane persons implies housing, clothing, food, sanitary and moral dis-

Tuberculosis of the Peritoneum, with Report of Cases.—This paper was read by DR. H. O. PANTZER, of Indianapolis. The author said that the prognosis and treatment of peritoneal tuberculosis have changed within the last decade. The accidental discovery of its curability by laparotomy has shifted its clinical relations. The author then quoted the conclusions of Dr. J. Whitridge Williams, from the Johns Hopkins Hospital Reports, 1892,

on tuberculosis of the female generative organs. He reported a case of primary genital tuberculosis, giving rise to a tubercular peritonitis, and tubercular disease of the abdominal parietes. Case II. was one of primary genital tuberculosis following a childbed sacculated ascites resembling an ovarian tumor. Laparotomy was performed and the patient recovered. Case III. was one of genital tuberculosis complicated with a suppurative infection and pelvic peritonitis. Laparotomy was done, followed by recovery of the patient.

This disease, from being regarded as a fatal and most intractable affection belonging to the domain of internal medicine, since its accession to the realm of surgery has come to be regarded as quite submissive. A mistaken diagnosis had repeatedly led to the opening of the abdominal cavity. Instead of an ovarian tumor, an enlarged gall-bladder, a hydronephrosis, or some other legitimate object of surgical interest being found, tubercular disease of the peritoneum in some of its multiple forms presented itself. The abdomen was closed without any attempt at treatment, or at most the ascitic fluid was evacuated. It was noted that these cases did better afterward, and that some fully recovered. In 1884 Koenig advocated laparotomy as a curative measure for peritoneal tuberculosis, and the operation has been done by other surgeons since.

Treatment of Diseases of the Uterine Appendages.—Dr. William H. Humiston, of Cleveland, O., read a paper on this subject, in which he said the frequency and importance of diseases of the appendages are recognized by all practitioners of medicine. The early recognition of the same is of unusual importance, as by instituting proper treatment at once we save a large percentage of them from a major operation and a prolonged convalescence. Simple inflammatory conditions of the tubes and ovaries, before extensive adhesions take place, can be successfully treated by rest, boroglyceride, and iodine tampons, long-continued hot water douches, thorough curettement of the uterus, followed by a course of galvanism. He had cured a few cases where the ovaries were prolapsed and somewhat adherent, by adding massage to the above treatment. But, as a rule, if the case has been neglected until pelvic peritonitis has occurred, with its tendency to adhesions and recurrence, we will save many years of suffering, if not life itself, by advising removal of the appendages after a sufficient trial has been given to conservative treatment.

Frequently, in the puerperal state we have a pelvic peritonitis arise without affecting the tubes, the inflammation spreading directly through the uterus; there is an exudate formed which rest and proper treatment will absorb and leave the appendages healthy, so that later pregnancy takes place and the patient goes on to full term. In these cases, if suppuration occurs, laparotomy should be advised. In tubercular salpingitis the question of removal will depend wholly upon the amount of general systemic infection. The author believes that nearly all suppurative diseases of the tubes and ovaries are due to gonorrhœa, his experience leading to this belief.

The author closed with a few words on the value of electricity in the treatment of inflammations of the uterus and appendages. He values this very highly, and in the catarrhal forms of endometritis in young girls and primiparæ, we can obtain a cure if sufficient time is given. He applies the positive pole intra uterine, and the negative in the form of a broad electrode over the whole abdominal region, using a current strength of from twenty to fifty milliampères for five minutes, every third day. It requires from fifteen to twenty applications to complete a cure.

SECTION ON GENERAL SURGERY.

Dr. W. N. Wishard, of Indianapolis, Chairman.

Some Illustrative Cases of Nasal Headache.—The first paper in this section was read by Dr. H. W. Loeb, of St. Louis, with the above title. The author, at the last meeting of the Missouri State Medical Association, presented a paper upon nasal headaches in which the following list of such conditions was suggested as possessing an etiological significance in this regard: Acute inflammations of the nasal mucous membrane, chronic rhinitis, rhinoliths and foreign bodies, septal deformities, deflections, spurs, ridges, diseases of the accessory sinuses, chronic atrophic rhinitis, and anything which causes the middle turbinated tissues to press against the septum. In headaches of the following characters, it was stated that a nasal origin might be expected: 1, Frontal headaches; 2, hemicrania, starting about the orbit; 3, long-continued headaches; 4, headaches of which successive attacks are identical or similar; 5, headaches increased or originated by acute rhinitis; 6, headaches associated with evident disease of the nose or accessory cavities.

In the present paper the author presented cases which illustrated the characteristics, both symptomatic and causal, as stated in the before-mentioned contribution.

Dr. B. Merrill Ricketts, of Cincinnati, reported several interesting surgical cases, and exhibited photographs of the same.

Treatment of Fractures of the Leg, by Dr. J. T. Berghoff, of St. Joseph, Mo. In treating fractures of the leg, the author said the latter should never rest on the bedding, but should be suspended. He cares not how well the surgeon may co aptate the broken bone and protect the same with splints and bandages, or plaster-of-Paris, if the limb rest on the bedding, by each movement of the body of the patient the fracture is bound to move. The process of repair is exactly the same in soft tissues and bones. Why do we have union by first intention? Because we co-aptate the wounds exactly, and keep them so. The wound heals sometimes in three days, at the farthest a week. But to put the broken limb in an immovable condition and keep it so without great suffering to the patient, cannot be done under the old system.

Dr. Berghoff then described an apparatus or splint, the outgrowth of patient study for twenty years, but more particularly the last ten years. The apparatus is also adapted for treating diseases of the hip, knee, and ankle joints, as the extension can be adjusted as the case requires, the joints being kept immobile.

Incurability of Advanced and Extreme Cases of Talipes Equino-varus by the Means and Methods in Vogue at the Present Time; Suggestion of a Way to Remove the Deformity without Disturbing the Usefulness of the Extremity, by Dr. Louis Bauer, of St. Louis. Dr. Bauer presented a plaster cast of a talipes varus in which the weight of the body rested upon the dislocated astragalus and calcaneum. He produced also the skeleton of a leg and foot of a person who died while in this condition. He showed that there was complete dislocation of the astragalus, that the knee-joint surfaces had formed between that bone and the calcaneum, whereby the weight of the body rested entirely upon the end of the astragalus and calcaneum; that the scaphoid and other bones of the foot bore little, if any, part in sustaining the weight of the body. It has been found impossible, in extreme cases of talipes, to restore the foot to its natural position by tenotomy, or by *brisement forcé*. In one case, after six years trial, the doctor had proposed an amputation similar to Chopart, whereby all bones anterior to the astragalus were removed. The operation would leave a linear scar anterior to the astragalus in its new position and would be out of the way, and in such direction the artificial foot could be easily adjusted. He had not had an opportunity of trying this method, but felt sure that this amputation was a proper method in those cases where, after long-continued efforts, reduction could not be effected. He also reported a case where there was extreme lateral curvature of the spine from distortion of the pelvis, in a young musician. He became satisfied that the deformity was due to the unnatural position, and therefore directed a long splint applied reaching from the axilla to the foot, and the pelvis was

gradually pressed toward the splint by an appropriate bandage. After a period of time, not stated by the speaker, the patient recovered.

In the discussion which followed Dr. Marsee, of Indianapolis, took strong ground againt tenotomy, tarsectomy, or amputation in these cases, holding the position that by *brisement forcé* with a wrench or club-foot stretcher, he could bring the most refractory case in normal position.

Dr. Wm. E. Wirt, of Cleveland, believes in resection of some of the bones, after the method of Phelps, in cases where tenotomy or linear osteotomy had proved unavailable.

Dr. John B. Hamilton, of Chicago, agreed with Dr. Marsee in recommending the use of a club-foot stretcher or wrench. He would not hesitate to employ a force sufficient to comminute the dislocated astragalus, if it were necessary to put the foot in position. He had seen no bad results following osteoclasis. The difference between osteoclasis, osteotomy, or tarsectomy, is precisely that between a simple and open fracture. In regard to abrasions of the skin, he had not met with any, and strongly preferred osteoclasis.

New Devices for Cutting Bone, by Dr. Allan DeVilbiss, of Toledo, O. Dr. DeVilbiss exhibited a surgical motor with various forms of saws and drills, which he developed through a series of practical tests. He had used them first upon the dead, afterward upon the living. These instruments were adapted for operations upon the skull, maxillary bone, ribs, nasal bones, etc.

The Treatment of Old Cases of Hip Disease.—Dr. William E. Wirt, of Cleveland, O., read a paper on this subject. He said there is no doubt that if convalescent cases of hip disease were carefully and persistently treated during a long period of complete recovery, whatever deformity had existed up to this time, and that which accompanies this period, could be entirely overcome without operation. When shall a case of hip disease be considered to have progressed far enough to permit the removal of the extension-splint and the substitution of a convalescent-brace? The solution of this problem was a matter of judgment. It is better to allow the extension-splint to be worn unnecessarily long than for the substitution to be made too soon. The deformities requiring correction are flexion and adduction. Dr. Wirt had been surprised in several instances of old cases of hip disease with considerable deformity, where, after the application of continuous extension in bed for a few weeks, the deformity would be considerably reduced. After a trial of extension in bed with a failure to reduce deformity, there remains as a means of correction: 1, *brisement forcé*, with or without myotomy, tenotomy, faciotomy, etc.; 2, osteoclasis; 3, osteotomy. These operations were then considered by the author under their respective heads. Osteoclasis and osteotomy are reserved for those cases in which there exists bony union or a fibrous anchylosis of a very firm character. The author reported sixteen cases following Grant's operation.

A Case of Senile Gangrene Treated by Amputation.—This paper was contributed by Dr. G. W. H. Kemper, of Muncie, Ind. The patient was a farmer, aged seventy-three. After detailing the particulars of the case the author drew the following deductions: 1. While the gangrene is confined to one or two toes, it is best to defer amputation. If the disease extends to the dorsum of the foot amputation is proper. 2. Amputation below the knee is rarely successful, owing to lack of proper blood-supply and tendency to recurrence of gangrene in the stump. 3. Amputation through the thigh will save a large per cent. of the cases, and especially so when the subjects are free from a general disease. Mansell-Moullin observes that usually the thigh is small and wasted in the lower third; the artery is sound in Hunter's canal; the flaps are well supplied with blood, and old people as a rule resent operation very slightly. Their tissues are not prone to inflammation. 4. When amputation has been performed below the knee, and gangrene appears in the stump, unless the patient is exhausted, it will be proper to perform a secondary amputation above the knee.

A New Method of Operating at the Ankle-joint for Injuries of the Foot.—Dr. I. N. Quimby, of Jersey City, N. J., read a paper with this title. The method consists of making a curvilinear incision across the dorsum of the foot, commencing anterior to and a little below the internal malleolus, and terminating at a corresponding point a little below the external malleolus, and then uniting the two extremities of the dorsal section by an incision across the sole of the foot, forming an anterior and posterior flap, similar to the operation performed by Pirogoff, of Russia. After forming a short anterior flap and turning it back, he then dissects out the astragalus from its attachments, being careful to keep close to the bone; then forming a linear posterior flap from the sole of the foot, he makes a careful dissection, exposing the anterior half of the calcaneum. This being done, and the soft parts being well retracted by an assistant, the saw is applied so as to remove nearly the anterior half of the bone by an incision from above downward and from behind forward. The sharp edges of the remaining portion of the bone are then rounded off, and the sawed surface is applied directly to the articular surface of the tibia between the malleoli, without removing any part of the cartilaginous surface. After stitching up the flap in the usual way, a strap of adhesive plaster is applied, three or four inches in width, extending from the upper portion of the gastrocnemius muscle to a corresponding point on the anterior surface of the leg, passing directly over the os calcis, so as to keep closely and firmly in apposition to the articular surface of the tibia, which is kept there until the union of bones has taken place.

The Bacteria of the Surface.—Dr. Frank J. Thornbury, of Buffalo, read a paper under this title, in which the latest researches were set forth, rational mechanical means of disinfection summarized, and the non-utility of antiseptics proclaimed. The varieties of organisms which the cutaneous and mucous surfaces present in great abundance, comprise moulds, yeast fungi, bacilli, cocci, color- and odor-producing bacteria. The hairy regions, as the axillary space, and the interdigital folds, are the places of predilection for the bacteria upon the cutis. Myriads of microbes are present in the oral cavity, the intestinal tract, the genital tract of the female, the male urethra, and in the conjunctival secretion and cerumen of the ear. Among the masses are germs which are pathogenic, as the Fehleisen streptococcus of erysipelas. The cleansing of the surface constitutes one of the most important duties of asepsis. This pertains especially to the physician's own hands. The disinfection cannot be accomplished by the use of antiseptics, so called, which do not even reach the bacteria imbedded in the substrata of fat and dirt. The disinfection must be mechanical, dissolving away the glandular secretions, dead epidermal cells, vegetable and albuminous substances. For the latter purpose soap, hot water, and brush are used, aided by alcohol and ether, and rubbing with sterile towels. Baths are an important adjunct to asepsis, and one or a number should be administered previous to operation.

The Etiology, Diagnosis, and Treatment of Ulceration of the Rectum, by Dr. Joseph M. Matthews, of Louisville. The author dealt with this subject in a general way. As a matter of convenience, he classified these ulcers under four heads: Benign, malignant, tubercular, and specific. He said to this division there might be a valid objection based upon correct pathological grounds. For instance, in this classification he makes the term malignant synonymous with cancer, and yet the tubercular ulcer may in truth be malignant without assuming the characteristics of cancer. Again, some writers would have us believe that a tuberculous patient is closely akin, at least, to a syphilitic one, or *vice versa*. Benign ulceration is not so frequently found in the rectum as is supposed. Whenever the author meets with a well-defined ulceration existing in the rectum, he immediately begins to suspect some special diathesis. It is

only when the facility of defecation is interfered with that any danger is to be feared. The lumen of this portion of the gut is not narrowed by any ordinary causes. For these and other reasons, Dr. Matthews has long since been forced to believe that such ascribed causes as pregnancy, dysentery, etc., were not great factors in producing ulceration of the rectum. The speaker then dwelt upon malignant ulceration of the rectum, saying that the rectum is a favorite seat for cancer. Many times the disease is overlooked entirely, or diagnosticated as some other affection. It has occurred to him several times to have had patients referred to him for some trivial rectal trouble, when he found cancer instead. The more he practises, the more he is convinced that syphilis is responsible for fully one-half of the cases of severe ulceration of the rectum.

The treatment must in every individual case depend upon the known character of it. We cannot treat a benign ulcer as we would a malignant one, nor a tubercular ulcer as a specific one, nor the last named as the first named. Benign growths of the rectum require local applications; malignant, extirpation; tuberculous, the curette; syphilitic, antisyphilitic and local medication, extirpation, colotomy.

Inguinal Colotomy.—Dr. Leon Straus, of St. Louis, read a paper with this title, in which he entered a plea for more frequent and earlier colotomy in painful malignant diseases of the rectum. Dr. Straus stated his reasons for making colotomy as follows: 1. It is the greatest modern surgical relief measure, inasmuch as it completely does away with the function of the rectum, thereby relieving the intense pain caused by defecation. Pain is an inevitable result in advanced malignant disease of the rectum. There are few exceptional cases, which only prove the rule. 2. The lease of life is extended. There are many instances where it has been considerably extended. So great authorities as Cripps, Allingham, and Eiselsberg claim to have extended the lease for weeks or months. Are not these most cogent reasons for making a colotomy? 3. The risk of the operation has been minimized. Allingham has made sixty-eight colotomies with only two deaths, and they were total obstruction cases. Cripps, forty-five, with one death; this was a total obstruction case. Edwards has made sixteen, with one death. The patient was very septic at the time of operation. Reeves has made sixty-five operations without a death. Goodsall has made twenty-two without a death. Statistics show a death rate of less than two per cent. By making early colotomy the author believes that the death-rate might be reduced to less than one per cent.

Kraske's Operation, with Report of Cases, by Dr. H. O. Walker, of Detroit, Mich. The author of this paper said that a man or woman who had cancer of the rectum was of few days, and the method of relief could be done in three ways, either by proctotomy and scooping away of the growth, by excision of the cancer, or by colotomy, all of which were temporary, as the author had never seen a case of true cancer that ever got well. When the malignant growth was high up, say two or three inches above the rectum, the best operation to make would be by Kraske's method, that is, by making an incision down through the second sacral vertebra to the anus, to the left of the coccyx, and rapidly stripping off the muscular and ligamentous attachments to the coccyx and cutting them away with the bone forceps, and as much of the sacrum as is necessary to expose the growth. Then we have a full view for enucleating the growth and excising it. It is well known that it is a difficult matter to approximate the ends by suture method, and an idea was forced upon Dr. Walker, from his knowledge of the Murphy button, that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum and by this means prevent the infiltration of fecal matter, which by the other method was an impossibility. In this connection Dr. Walker said he had made the first end-to-end approximation by the Murphy button in a case of fecal fistula, on December 8th, and the patient on whom he had operated made a good recovery and within two weeks the patient was as well as ever, with no evidence of any contraction of the intestine.

Some Heresies Regarding Prostatic Pathology.—This paper was contributed by Dr. G. Frank Lydston, of Chicago. The author said that among the many ills which were marked *noli me tangere* until recent years, and which modern surgery has done much to relieve, prostatic hypertrophy occupies a very prominent position. The surgical resources at present at our command were then briefly stated. The author is becoming daily more firmly convinced that the ideal operation is a combined supra-pubic and perineal section performed at an early period. He believes that in many cases this early operation will not only forestall circumscribed prostatic obstructions, median or lateral, but will prove directly curative by restoring the normal function of micturition. Supra-pubic cystotomy is undoubtedly the best method of draining the bladder, as far as a single operation is concerned, and in many instances it is all-sufficient. When combined, however, with perineal section, prostatic dilatation, and prolonged drainage by a large tube, we often do away with certain conditions which exist in the way of contracted lumen of the prostatic urethra and hyper-excitability of this portion of the urinary tract, which supra-pubic cystotomy alone might not accomplish.

Dr. Lydston believes that the main factors in the etiology of prostatic disease are laid down in many cases, if not the majority, before middle life.

Inguinal Hernia, its Anatomy, and Better Methods for Cure.—The surgical address before the general session was given by Dr. Henry O. Marcy, of Boston, the subject named having been selected by a request. Dr. Marcy illustrated his lecture by a series of slides reproducing the magnificent illustrated work of the old masters—Kamper, Cooper, Scarpi, Bougerey, and others. By general consensus of opinion the profession is indebted to Dr. Marcy as an innovator in this field of labor. He has established the value of the buried animal suture, and published his results quite five years before those of Weith, of Germany, to whom in Europe the credit is generally attributed. The essential principles of his operation for hernia have become universally accepted. The result of the work of a large number of the modern operators gives from seventy to ninety per cent. of permanent cures. In *résumé* Dr. Marcy claims that the peritoneal sac, as a rule, should be resected after suturing quite to its very base; that the deeper structures which go to make up the posterior wall of the inguinal canal should be reinforced and restored to their original normal condition; that the external wound should be closed without drainage and the skin wound sealed with iodoform collodion. In his large experience, involving several hundred cases, he states that where the intestine has not been involved from strangulation or other cause, not one of his patients has appeared to approach the danger-line, and that of the entire number which he has been able to trace, more than ninety per cent. have remained after one year permanently cured.

Papers were also read before this Section by Drs. William N. Wishard, of Indianapolis; J. McLean Moulder, of Kokoma, Ind.; William T. Belfield, of Chicago, and others.

Election of Officers.—The following officers were elected for the ensuing year: *President*, Dr. X. C. Scott, of Cleveland, O.; *First Vice-President*, Dr. Leon Straus, of St. Louis; *Second Vice-President*, Dr. G. Frank Lydston, of Chicago; *Secretary*, Dr. Frederick C. Woodburn, of Indianapolis; *Treasurer*, Dr. George J. Cook, of Indianapolis.

Hot Springs, Ark., was selected as the next place of meeting.

After drafting and adopting resolutions of thanks, the Association adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

MEDICO CHIRURGICAL SOCIETY—MULTIPLE JOINT DISEASE—MEDICAL SOCIETY OF LONDON—GRAVES'S DISEASE—GYNECOLOGICAL SOCIETY—REMOVAL OF UTERUS BY CAUSTICS—HARVEIAN ORATION AT THE ROYAL COLLEGE OF PHYSICIANS—ILLNESS OF SIR ANDREW CLARK.

London, October 28, 1893.

On Tuesday last, 24th inst., the Medical and Chirurgical Society began its sittings. After a resolution of sympathy with the family of Sir Andrew Clark on his serious illness, the Marshall Hall prize was formally presented to Dr. Gowers, who expressed his extreme satisfaction at receiving this honor. A paper was then read by Mr. Bowlby on a case of multiple joint disease in a lad of thirteen, probably due to hereditary syphilis, in which death resulted from amyloid disease of the viscera. The post-mortem showed gummatous masses on the calvaria, old cicatrices of the pharynx and disease of both elbows, both knees, the right shoulder, both tibiæ, and both humeri. It was suggested that in chronic arthritis in children with congenital syphilis, such lesions of joints may be of the same type. Mr. J. Hutchinson, Jr., said the microscopical examination excluded tubercle, and the evidence of chondritis with fibrillation of cartilage showed it to be specific, according to Virchow, who had described similar cases. Moreover, the presence of a subsynovial gumma proved it. He said that symmetrical synovitis following interstitial keratitis, usually cleared up under treatment.

Mr. Shield said most surgeons met with somewhat similar cases, and absence of corneal changes would not suffice to exclude syphilis. The demarcation between tubercle and syphilis was obscure, and perhaps the two processes might be mixed. Lupus attacking congenital syphilitics was very severe.

The subject of Graves's disease occupied the attention of the Medical Society of London at its first meeting for the session. A paper was first read by Mr. A. Maude on some of the less known factors in this interesting disease, and a discussion followed in which various suggestions were made. Mr. Maude insisted that enlargement of the thyroid body was constant, though occasionally it might be slight or transitory. His statistics opposed a common notion, that it is not often seen in goitrous subjects, for he had found 12 cases out of 55 of enlarged thyroid collected in a population of about three thousand. Out of 7 cases detailed, one was the child of a myxœdematous mother, and the connection between these two diseases seems now fairly established. The results of excision of the thyroid, of which he had collected 20 cases last year, pointed in the same direction. The psychoses observed in addition to the usual irritability of temper were: *a*, oversensitiveness as to duty slightly removed from religious melancholy, with delusions of sin; *b*, incoherence of ideas, ambulatory epilepsy, vertigo, tinnitus. The very frequent, almost universal, symptom of tremor was most marked in the flexors of the arms, the interossei escaping. This tremor exactly resembled that caused in animals after removal of the thyroid, and was much more uniform than that of hysterical tremor, for which it might be mistaken. Mr. Maude reviewed the bulbar symptoms, said that many nerve symptoms pointed to peripheral neuritis, and suggested that the disease was due to a toxic substance acting chiefly on the medulla, and probably proceeding from the thyroid. In the discussion Dr. Hall said some cases had been improved after intra nasal operations, and thought this might very well be the case if the disease arose in the sympathetic. Dr. Savage held there was no connection between goitre and Graves's disease, for he had not met with one case of the latter in 1,000 cases of the former which he had collected. Dr. Pasteur said the exophthalmic cases were rare in Switzerland. Dr. Murray insisted on the oppositeness of Graves's disease and myxœdema, and suggested that the former may be due to excessive activity of the thyroid, and the latter to deficiency of the secretion. He pointed out that when too large doses of thyroid extract are administered it gives rise to accelerated pulse, moist skin, tremor of the hands, and muscular wasting, just as in Graves's disease. Dr. Ord had seen rapid reduction of the thyroid in this disease followed by myxœdema, and assumed greater vascularity of the gland at first had been followed by atrophy or destruction of the secreting structure. Other speakers said thyroid extract had not, in their experience, aggravated the symptoms, that there was often spontaneous amelioration of the disease which extended over long periods, and that the sympathetic theory was not yet dead and buried. Some microscopical sections were exhibited by Mr. Berry, to illustrate the appearances met with in the two diseases.

Removal of the uterus by caustics was the subject brought forward at the first meeting of the Gynecological Society, when the President, Mr. B. Jessett, showed three specimens. He had employed zinc chloride on cotton wool after removing the diseased tissues as far as possible by his dredger, protecting the vagina by tampons of sodium carbonate. Great necrosis had occurred in one case, a portion of the rectal wall having sloughed with the uterus, and the fæces therefore passing per vaginam. Still no other bad effect followed, and pain and discharge ceased, so that the patient, like the other two, lived longer with less suffering. Of course he would not run the risks of this plan when hysterectomy was possible. In the discussion various questions were raised as whether the whole uterine peritoneum had come away, whether the pelvic vessels were endangered, or must we run the risks of a happy-go-lucky procedure, the strength of the chloride to employ so as to avoid the extensive sloughing that occurred in these cases. Mr. Jessett had treated some 20 cases previously, but had not seen such complete necrosis before. The pathologist of the Cancer Hospital reported that one of the cases was epithelioma, the other two scirrhus. Dr. Routh said that any caustic would do. He had himself used sea-tangle tents dipped in bromine diluted 1 to 5. He could also recommend acid nitrate of mercury. In 1848 he saw Dr. Hugnier, of Paris, employ caustics. Dr. Bantock had used caustics in a few cases, but it was not very easy to regulate their action, and when such sloughing occurred as in the specimens, danger to the intestines and other structures was great. Dr. H. Smith had also used this method, which was first employed by Marion Sims.

According to custom on St. Luke's day (October 18th), the Harveian oration was delivered at the Royal College of Physicians. This oration has, for many years, been devoted to the honor of Harvey. It was founded and endowed by him—not for that purpose, but in commemoration of all benefactors of the college, and the lecturer was directed to add "an exhortation to others to follow their example and to search out the secrets of nature by way of experiment, and for the honor of the profession to live in mutual love and affection." But Harvey's name has overshadowed other benefactors and explorers, and the oration has continued to be in commemoration of him. Dr. Pye-Smith was the selected orator this year, and followed the tradition. It is not easy to say, under such circumstances, what has not been as well said many times before. After discussing the discovery of the circulation and the treatise on generation, Dr. Smith referred to a third phase of Harvey's intellectual work, of which the records have perished, but of which he found some indications in his writings. He held that Harvey contributed, or would have done, but for the adverse fate which destroyed or dispersed his MSS. when he was with the king at Oxford, a systematic study of morbid anatomy. In one passage at least, Harvey speaks of the benefit that would ensue from the regular observation of the structural changes produced by disease. This was then a novel notion. Though bodies were opened for

embalming and other reasons at that date, there was no systematic observations of the organs after death for some one hundred and fifty years afterward. But Harvey recommended the study and had himself recorded many autopsies that he had made. Had these reports been preserved, the study of morbid anatomy would have, no doubt, begun a century and a half earlier, and the orator pointed out some of the might-have-beens suggested by this fact. In his exhortations, Dr. Smith denounced the anti-vivisectionists, and defended the profession from the unjust charges of cruelty and the reckless falsehoods propagated by ignorant sentimentalists, and expressed "a hope that those who administered our laws will take heart of grace, and in this, as in other matters, try whether Englishmen do not prefer the conscientious maintenance of a statesman's own judgment before a time-serving subservience to ignorant clamor."

Sir Andrew Clark is seriously ill, and the gravest apprehensions are entertained by his numerous friends. As one of these, I was shocked when I heard on Thursday afternoon (the 19th inst.) that he had been seized with paralysis during his morning work, and was for some time insensible in his study. So much consternation prevailed at the house that somewhat contradictory reports were given to callers. Eventually, however, it was made known that the attack was one of right hemiplegia with aphasia. He partially recovered consciousness and has improved as to this condition, but the paralysis of both arm and leg is complete and speech is still very disordered, although with an effort he can make himself understood. This attack was unexpected, he was at his work as usual when seized. On the previous day he was at the College of Physicians at the Harveian oration mentioned above, but was late in arriving and seemed to have mistaken the hour. This must have been an annoyance to him, for when I was chatting with him some time ago he expressed his great satisfaction to me that he had never missed a meeting since he had been President, and, moreover, had never been late. He told me, too, that he would not hold the presidency except with the determination to sacrifice all practice which could interfere with the fullest discharge of its duties.

THE NEED OF A NATIONAL BOARD OF HEALTH.

To the Editor of the Medical Record.

Sir: I notice in your issue of September 30th, a communication from a gentleman who is of opinion that there is no necessity for a National Bureau of Health, and says that the different State Boards of Health can answer the purpose. There are several objections to that theory. First, the gentleman seems not to be aware of the fact that some States of the Union have no Health Board. Secondly, many of the States have a Health Board only in name; and in others the Board of Health simply offers positions for political wire-pullers. Thirdly, in some States the Commissioner of Health takes a real interest in medicine and sanitary science, and wants to do something for the public health, but for some reason or other his hands are tied and he can go so far and no further.

Modern scientific investigations have shown that there are such things as contagious diseases, due to bacilli, and that these bacilli can travel from one person to another, and from one place or country to another; and it seems to me that in view of these facts the matter of public health becomes not only a national question but also an international one. The question of public health is one of national consideration, and calls for international co-operation. State lines are not respected by epidemic intruders, and State Boards of Health have no jurisdiction outside of their State limits. If a body of competent, independent, non-partisan medical men were to be appointed by the Federal Government, and invested with independent executive authority in matters pertaining to the public health, the members to be well paid, and to devote their entire time and attention to the administration of sanitary laws, we should find things quite different and greatly improved. If, for example, an important question is brought up that is universal in its application, only a national Board of Health could properly deal with it. At the Pan-American Medical Congress held in Washington, September 7, 1893, in the Section of Hygiene, Climatology, and Dermography, it was resolved that tuberculosis causes more deaths than any other disease, and that it is known to be communicable, especially to persons living in houses and shops with consumptives. Now if such an important question as that were to be taken up and properly considered by a National Board of Health having authority to deal with it, the preventive measures could be at once put in working order, and something practicable would be done.

Another example is found in the news columns of the public press a few days ago, where it is announced that two Italian steamers, the Carlo R. and the Remo, arrived at Santos from the Mediterranean with cholera and were not allowed to land; the passengers were obliged to re-cross the Atlantic, and during the homeward passage the pestilence became more virulent, and one hundred and fifteen passengers of the Carlo R., and sixty-four of the passengers and crew of the Remo, perished of the disease. These examples show the need of an international quarantine system, as well as the somewhat selfish measures of individual nations for their own protection. The sending back of these ships was not at all in the line of sanitation or stamping out the plague, but, on the contrary, tended to increase it and sacrifice lives that might have been saved.

There are certain infectious diseases that only originate in some Eastern lands, but diseases are portable, and are frequently conveyed from their original habitat to other parts of the world, where, if they find favorable conditions for propagation, they develop and spread. The infectious germs of cholera are produced in India, and from there they have been carried to almost every part of the globe. If proper sanitary regulations were to be adopted by the various maritime nations the scourge of cholera would be stamped out in its breeding-place and would soon become a thing of the past. It seems to me that every intelligent physician who is familiar with sanitary science and knows what sanitation has done and might do to improve the health of the people, will range himself on the side of a National Board of Health, and do what he can to secure the passage of the bill in the United States Senate.

Leonard Landes, M.D.

976 Lexington Avenue.

IS MEMBRANOUS CROUP CONTAGIOUS?

To the Editor of the Medical Record.

Sir: The accompanying report by the Chief Inspector of the Division of Pathology, Bacteriology, and Disinfection of this Department is of very great interest to the medical profession and of great importance to the community. The Board of Health requests the co-operation of the physicians of this city, in order to definitely establish or refute the contagiousness of so called membranous croup. The fact that in a large majority of the cases of membranous croup (not apparently involving the pharynx) examined bacteriologically by the officers of this Department, swabs infected with the pharyngeal secretions were shown to contain the Loeffler bacillus, tends to the conclusion that membranous croup is laryngeal diphtheria, and that, as is shown in the report, it is liable to cause cases of like character, or of diphtheria of the ordinary type. Before declaring the disease to be contagious and classing it among the transmissible diseases which must, under the law, be reported to the Board of Health, the Board desires to have the results of the bacteriological investigation of a large number of cases tabulated in order

to base its action on irrefutable premises. The only way that this can be done is through the voluntary report to this Department by physicians of cases of membranous croup that may occur in their practice, with request for a bacteriological examination.

Therefore the Board respectfully requests physicians to report cases of membranous croup under that name, in the same manner that they report cases of contagious disease. The data already obtained is sufficiently convincing to cause this request to the profession, to treat membranous croup as a contagious disease; that is, to advise isolation and disinfection the same as in a case of diphtheria.

CYRUS EDSON, M.D.,
Commissioner, and Chairman of the Sanitary Committee of the Board of Health of New York City.

HEALTH DEPARTMENT, No. 301 MOTT STREET,
NEW YORK, November 3, 1893.

HON. CHARLES G. WILSON, *President.*

SIR: In compliance with your request I have the honor to submit the following report of the results of the bacteriological examinations made in cases of so-called membranous croup. These are cases from which cultures have been referred to this Department for examination because of the suspicion that they were of a diphtheritic nature.

During the last four months bacteriological examinations have been made in thirty-six cases of this kind. In all of these the membrane was either confined entirely to the larynx, or at most only slight deposits existed in the throat, while there was very extensive exudation in the larynx. In thirty of the cases the Loeffler bacillus of diphtheria was abundantly present. These cases therefore were really cases of laryngeal diphtheria. In six cases no Loeffler bacilli were found; these were therefore cases of catarrhal pseudo-diphtheritic inflammation of the larynx, and are to be considered analogous to similar pseudo membranous inflammations (non-diphtheritic) in the pharynx.

In five of the laryngeal cases in which the Loeffler bacillus was found, cases of pharyngeal diphtheria both preceded and followed within a week in the immediate vicinity. In three other instances the cases of croup were preceded by cases of true diphtheria, and in seven instances were followed by cases of true diphtheria. In the remaining fifteen cases of membranous croup pharyngeal diphtheria neither preceded nor followed in the immediate vicinity. None of the six cases of croup in which no Loeffler bacilli were found were followed or preceded by cases of diphtheria.

During the last four months, therefore, nearly eighty-four per cent. of the cases of so-called membranous croup referred to this Department for bacteriological examination have proved to be diphtheria.

(Signed) Respectfully,
HERMAN M. BIGGS.
Chief Inspector.

HEALTH DEPARTMENT, 301 MOTT STREET,
NEW YORK, November 1, 1893.

Congenital Absence of Nails.—Dr. Eichhorst reports the case of a man, twenty-six years of age, who had no nails on either fingers or toes. The nail bed and fold were well formed, and the former presented a shiny surface, giving the appearance of a very thin nail. Close examination showed, however, that there was not the slightest trace of a nail, the skin of this part being softer and more delicate even than the surrounding integument. Sensation was also as acute here as on the palmar surface of the fingers.—*Centralblatt für klinische Medicin.*

No Change.—BRIGGS: You say your doctor sends you a bill twice a year?
GRIGGS: Yes.
BRIGGS: What does he do that for?
GRIGGS: It's the same bill.—*Judge.*

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 4, 1893.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	25	9
Scarlet fever	59	3
Cerebro-spinal meningitis	4	8
Measles	135	8
Diphtheria	143	49
Small-pox	14	0
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

A Suggestion Regarding Improved Hip-splint.—Dr. F. Overholt, of Omaha, Neb., writes: "I have the MEDICAL RECORD of October 28th, the foremost article in which is one on hip-joint disease by Dr. Judson, which calls to mind the numerous hip-splints devised. It has often occurred to me that some one ought to devise a hip splint employing the idea in a bicycle saddle to obtain support and extension from the tuber ischii instead of with a perineal band. Having worn a hip-splint for a year or two some years ago, I may be said to be conversant with the disadvantages of the perineal band. I merely offer this as a suggestion, having done no experimenting, and, being in other work, have no opportunity to do so."

English Diplomas and Practice Abroad.—Further communications have been received from the Foreign Office, through the Privy Council Office, in reference to the question of reciprocity of practice for English medical men in foreign countries. Reference was made to communications received from the Governments of France, Italy, Germany, and Switzerland. It will be remembered that the restrictions on the practice of foreign medical men in France, though objectionable, were not very oppressive; in Italy there is virtually no restriction; and for practising the healing art in Germany no special official permission is required, but any one wishing to practise as a doctor or to be recognized or intrusted with official duties must receive a certificate which can be granted only after an examination. In regard to Switzerland the Federal Government are quite willing to grant all facilities to foreign practitioners, but the Medical Board, which has a decisive voice in such matters, remains firm in its opposition to any idea of reciprocal arrangements with this country. Thus this small community evinces a most illiberal spirit toward those medical colleagues who have made the health-resorts of their country of such importance as they possess, and shows an indifference to the welfare of the sick such as might be secured by medical men of their own country, forgetful that the pursuit of the healing art should know nothing of territorial boundaries or restrictions provided that due protection was afforded against ignorance and incompetence. Further communications on the same subject have been received through the Privy Council since the last session of the Council and will be laid before the members. It would appear that in Sweden the Chancellor of the University of Stockholm has already power to grant, in case of licensed practitioners, a certain reduction of the time required to obtain a qualification to practise. In Norway the Government can authorize individual foreign medical men to practise in practically the same manner in which the British law permits foreigners to practise in the United Kingdom. In Portugal measures of a provisional, incidental, and limited nature have been adopted, which are in accordance with the

privileges granted to foreign practitioners in the United Kingdom. In Denmark nothing can be done which would differentiate British from other foreign practitioners. It will thus be seen that great facilities, almost amounting to reciprocity, are afforded in many European countries, but that lesser facilities are afforded by France and Switzerland, especially the latter, where some of the chief health-resorts are situated. The special action of the Swiss Medical Board will no doubt tend to the establishment of health-resorts of equal value in other situations, where the sick will not be deprived of that valued medical assistance on which they can rely. Such resorts are to be found in Italy, Egypt, the Cape, California, Madeira, the Canary Islands, Australasia, New Zealand, and at home. Some of the places named, though distant, can be reached by sea voyages, which in themselves contribute so largely to the restoration of health.—*The Lancet.*

Treatment of Suppurating Buboes.—Dr. Otis gives an account, in the *Journal of Cutaneous and Genito urinary Diseases*, May, 1893, of his treatment of suppurating buboes. The skin around the affected part is first rendered aseptic by scrubbing with soap and washing with sulphuric ether, and then bichloride of mercury solution, 1 in 1,000. A narrow bistoury is next inserted into the suppurating part and the contents well squeezed out. The cavity is now irrigated with a solution of mercuric chloride, 1 in 1,000, and immediately filled to moderate distention with warm iodoform ointment (ten per cent.), introduced by means of an ordinary conical-pointed glass syringe. Care must be taken not to apply heat sufficient to liberate free iodine. On withdrawing the syringe from the wound, a cold compress, wet with bichloride solution, is applied, which solidifies the ointment at the orifice. A large compress of bichloride gauze is then applied and held in position by a spica bandage. Sixteen cases were treated in this way, and of these, 9 were cured in six days, 3 in twelve days, 1 in fourteen days, 1 in twenty-three days, and 2 ceased attending during treatment. Otis claims for this procedure, 1, that it is simple and safe; 2, in suitable cases cure as a rule seems to be more rapid than by any other method; 3, the patient is not prevented from going about during treatment; 4, the first gland being rendered thoroughly aseptic, other glands in the chain are less liable to become infected; 5, no scar is left; and 6, it does not interfere with the performance of any subsequent surgical procedure which may be requisite.

Fantastic Therapeutics.—The fantastic character of recent therapeutic suggestions will, it is feared, cause a revulsion of feeling in favor of therapeutic nihilism. The science of therapeutics is particularly subject to the fluctuations imposed upon it by the idealism of its votaries. But, as Sir Thomas Browne somewhere observes, "every poison contains its own antidote," and the excesses practised by the insistent therapeutist engender a corresponding scepticism and mistrust, which ultimately save this much-abused science from the oblivion of ridiculousness. These two traits, this confidence of the believer and the incredulity of the doubter, are admirably exemplified at the present time. On the one hand, it is found that the ideas which have resulted in the concoction of microbic and animal-extract panaceas for every ailment have devastated the reason of the therapeutist. The very reasonable hypothesis that the various glands supply an internal secretion to the blood necessary to its maintenance as a vitalizing medium has been twisted into the baseless fabric of a vision of every organ secreting or manufacturing specific nutritional substances. In harmony with this conception, a system of therapeutics is suggested which smacks of sixteenth-century enlightenment; in which extracts of various organs are administered for diseases of homologous parts. On the other hand, we find a distinguished German observer carrying his nihilism to the extreme of contending that all the results of electro-therapeutics are those of suggestion. Between so much faith and so little, where do we stand? Shall we next hear that opium relieves pain and chloroform produces anæsthesia by suggestion? or shall we learn that zygomaticin is extremely beneficial in melancholia? One of the potent causes of this therapeutic befuddlement doubtless arises from the proprietary interest in remedies. The profession is perpetually deluded by those who claim to enlighten it by carefully prepared information of an unreliable kind, regarding the physiologic and clinical action of remedies. This makes it more and more incumbent upon the intelligent physician to limit his prescriptions to the actual materia medica, of which he possesses definite and reliable information. It would be sad to think that nothing should result from this outrageous idealism in therapeutics. If it be that "the end of dreams is to break them," let them be broken rudely, provided this restore us to a fair degree of therapeutic sanity.—*The Physician and Surgeon.*

Kleptomania in the Consulting-room.—A correspondent of *The Lancet* gives the following account of a recent incident: "Sicily, the classic haunt of brigandage, seems ambitious of showing that highway robbery does not quite exhaust her methods of breaking the eighth commandmant. Some days ago, in Palermo, a well-dressed, pleasant-mannered young man was ushered into the presence of one of the leading alienists and proceeded, on painfully matter-of-fact lines, to state the object of his visit. His dear wife had during the few months since their marriage developed the most distressing, most incorrigible, habit of kleptomania. Not only in public shops and in private visits, but even in her own house, she could not keep her hands off other people's property, which, however, on coming to her real self some hours afterward, she invariably returned to their owners. Medical treatment had hitherto failed to wean her from the habit, and in his despair he bethought him of the Palermitan expert, whose success in such cases had come to his knowledge. The consultant, having put a few questions, which were intelligently answered, expressed his willingness to take the young lady in hand, and appointed an hour on the following day when her husband was to bring her to him. True to time the pair arrived, and the lady had hardly been introduced to the consultant when her beauty and frank, engaging manner imparted a quite peculiar interest to her case. During the interview she conducted herself like a high-bred woman of the world, except for the unfortunate failing she labored under—pocketing articles of value when she thought she was unobserved. Among these the vigilant eye of the consultant missed a photograph framed in brilliants (the gift of a patrician patient) and also a beautifully modelled statuette of pure gold. He also remarked that just at the moment of bidding him good-day she relieved him in the quickest and most graceful manner possible of a valuable cravat-pin which became 'secreted about her person' with the suddenness of magic. 'You see yourself,' groaned the afflicted husband in an aside to the consultant, 'how possessed she is with the thieving instinct. Oh! my poor, unfortunate wife! I will bring you back all the missing articles tomorrow at any hour you may appoint, when you will kindly give me your opinion of the case and advise me what to do.' To-morrow came and with it the appointed hour, and the consultant waited, and is still waiting, for the 'well-dressed, pleasant-mannered young man' and his stolen goods. He was as cleverly swindled as Gil Blas was by Don Raphael and Camilla, 'niece of the Governor of the Spanish colonies in the Philippine Islands.'"

The Chess Memory.—M. Alfred Binet has published a study of chess memory, founded mainly on communications made to him in reply to a set of questions by many of the most eminent living blindfold chess-players, supplemented in some instances by actual observations made in the psychological laboratory of the Sorbonne. He comes to the conclusion that the player relies mainly on visual memory, but partly also on verbal memory; the

more accomplished the player, the less distinct is the mental picture of the board and the pieces. Such a picture appears to be formed by all, but the verbal memory seems to be of little importance, and, as a matter of fact, the players rely less upon a mental picture or echo than upon a recollection of the relative position of the pieces which are recalled, not as possessing a particular form or a particular name, but as being endowed with certain powers. This is confirmed by the experience of several players, who state that when engaged in playing several games at once they distinguish between them by recollecting the character of the opening. When called upon to move in a particular game the act of memory is described by Dr. Tarrasch, the German champion, who is a medical man, somewhat as follows: He is told that in game number so-and-so his adversary has moved, and the nature of the move. At first his mind is chaos, the one fact which stands out being the nature of his adversary's move. Then he recalls the whole game, the first fact being the nature of the opening. "Ah," he says to himself, "that is the knight's gambit in which the opponent defended according to custom until such-and-such a move;" then he runs over each move that has been made until he comes to the last move just announced to him, which then fits into its place; then he has a dim image of the board with the pieces in their proper places. How far this process is a matter of verbal memory is not very clear. It is really the recalling of a series of incidents linked together by a chain of reasoning, and M. Binet adds the interesting fact that the blindfold player is very apt to forget, or to have difficulty in recalling, isolated or purposeless moves of his adversary. A good player will remember every move in an interesting game for a long time—months or years. Mr. Paul Morphy, for instance, on one occasion dictated from memory—not as a feat but in order that they might be published—eight or ten games that he had played eight months earlier. A blindfold player must have a good memory, but it is a very different sort of memory from that of the calculator Inaudi, who can recall long strings of unconnected numbers which he has heard recently. His memory is, however, short. M. Binet found on trial that Inaudi could recall three hundred numbers; these had all been heard within the two previous days. Numbers heard earlier had been entirely forgotten. The difference in retentiveness is, no doubt, due to the fact that in Inaudi's case there was no connecting link to bind the series of figures together, whereas the chess player's memory is not a memory of mere sensations, but of ideas.—*The British Medical Journal.*

The Influence of State Boards of Medical Examiners on Medical Teaching.—A physician writes: "A few years ago, when I studied medicine in one of the metropolitan schools, the course was two years—winter session, of not more than five months; spring session, of three months, for those who might wish to attend, and the number was usually small. Students were expected to be present at all the lectures, but often were not. Each professor was supposed to 'quiz,' for about an hour each week, on the lectures which he had delivered that week, but attendance was not compulsory, and few joined the class. The final examination was wholly verbal, and seldom a dozen questions were asked by each professor. Yet I never heard a student complain of this system. How different at present, and presumably because, in large part at least, of legislative enactments providing for State boards of medical examiners. My brother, who is attending the same medical school, will have to go at least three years. The winter course is two or three months longer than formerly. Students are ranged in classes, there being about three classes, of thirty or more, in each department—chemistry, physiology, materia medica, etc. An adjunct professor in each department 'quizzes' his classes once, or oftener, a week for an hour, and assigns them so many pages in the text-book for the next recitation, just as is done in the public schools. A percentage of ten, or perfect, is credited to those who recite without an error, and absentees are given zero. This percentage counts on the final examination. The latter is largely written. Class instruction extends also to laboratory work and clinical study at the bedside. Of course didactic lectures take place as formerly. The whole course is planned and carried out apparently with an appreciation of the fact on the part of the faculty that each graduate, before he can enter upon practice, will be examined by a State board which will show no mercy, and failure before such board will reflect discredit upon the institution granting the diploma."

The Weight of the Two Sides of the Brain.—Professor Braune, of Leipsic, has recently published the results of weighing the halves of 100 human brains. These were divided in the median line, and the cerebellum, with the medulla and pons, were cut off and bisected. The weights of the two sides of the whole encephalon were compared, as well as that of the cerebral hemispheres, and the halves of the cerebellum with the medulla and pons. It has generally been taught that the left half of the brain is heavier than the right, and that this is a physical cause of right-handedness. The results of Professor Braune's investigations do not seem to bear this out. He found the left side of the entire brain heavier in 52 cases, and the right in 47 cases, the two sides being equal in one case. And he also found that if the excess of weights of the two sides be added up, the right side showed a preponderance, the difference between the two sides being in most cases so slight as not to deserve any consideration. In five cases in which the right side considerably out-weighed the left, the bodies were examined for signs of left-handedness, but none were found. The left cerebral hemisphere was the heavier in 54, the right in 37 cases; while the left side of the cerebellum was the heavier in 54 and the right in 33 cases. Thus he found that the cerebral hemisphere of one side is the larger about as often as the cerebellum of the other; but the larger halves are on the same side about twice as often as on different sides.—*Boston Medical and Surgical Journal.*

Conception during the Puerperal Period.—Dr. Brasseur relates the case of a woman, twenty-two years of age, who was delivered on July 4, 1892, of her first child, July 8th she practised coitus, and was again delivered March 10, 1893, of a healthy child. Calculating from the date of coitus, the second pregnancy lasted two hundred and forty three days, that is, twenty-seven days less than the normal. This case has caused considerable discussion. Ovulation must have existed in the woman on the fourth day after the delivery, and it was necessarily quite independent of menstruation. Dr. Koenig, who actually observed the case, draws from it the following deductions: 1. A gestation period of two hundred and forty-three days after a fecundating coitus may produce a viable child. 2. The spermatozoa can live in the lochial secretions. 3. The functional activity of the ovaries is not completely suspended during pregnancy. The Graafian follicles so open that they may burst a very short time after delivery. 4. Ovulation and menstruation may occur independently of each other. 5. Among vigorous women, during the period immediately following confinement the uterine mucous membrane may undergo a rapid regeneration which renders possible the implantation of a fecundated ovule immediately after delivery.—*Gazette Médicale de Liège.*

THE TREATMENT OF ENTERIC FEVER.[1]

BY GUSTAVUS ELIOT, A.M., M.D.,

NEW HAVEN, CONN.

THE great mortality and wide prevalence of enteric or typhoid fever justify frequent discussion of its treatment. It is an important duty of the medical profession to try to discover such principles and methods of treatment as will diminish the severity and fatality of the disease, and to promote their dissemination.

I shall not attempt to bring forward any therapeutic novelties. Every remedial measure of which I shall speak was proposed and tried long ago. It is the modest purpose of this paper simply to discuss those principles and methods of treatment which are in more or less common use, and to point out those whose value has been most thoroughly established and which seem worthy of general adoption.

The first requisite in the successful treatment of enteric fever is rest. As soon as the physician begins to suspect that his patient has this disease it is his duty to insist that the sick person should at once go to bed, and should remain there, in the recumbent position, until all doubt in regard to the nature of the disease has been dissipated, or until the patient has entirely recovered. Everyone, unless he is a fool, knows that, you are saying to yourselves. Let me remind you that a little less than nine years ago Frederic Mahomed, one of the assistant physicians of Guy's Hospital, London, died at thirty-five years of age, of enteric fever, and that a few days before his death, while his temperature was 104° F., he left his residence and went to the hospital to see a student ill with rheumatic fever. Certainly this brilliant young Londoner ought to have known, even so long as nine years ago, the importance of rest in the treatment of enteric fever. Let us hear from his own lips the reason why he disregarded this fundamental rule. It was addressed to his wife: "Would you have me stay at home for a bilious attack when the life of another is in danger?" These words of a young man of extraordinary promise may serve to emphasize a point of the very greatest importance in this connection. It is the necessity of making an early diagnosis, if one wishes to treat enteric fever with the best results. If the brilliant young assistant physician of Guy's Hospital had realized that he had this disease he undoubtedly would have remained in bed, and very likely would have recovered, to continue his investigations in cardiac and renal pathology.

Many reputable physicians have, at some time in their experience, been guilty of this same carelessness in diagnosis, and have allowed patients, whom later developments showed to be suffering from enteric fever, to remain out of bed, or even to continue about their business. And this was permitted, not because the physician did not know that patients with enteric fever must be kept in bed, but because at first he failed to recognize the real nature of the disease. The best results in the treatment of this disease will never be obtained until the time comes when no physician allows a patient who has any elevation of temperature to remain out of bed, until he has positively and absolutely excluded the possibility that the patient has enteric fever. Every physician ought always to assure himself that his patient has no fever before he ventures to prescribe; and ought always to assure himself that a patient with any elevation of temperature has not enteric fever before he permits him to remain out of bed. The general observance of these simple rules would greatly diminish the mortality from enteric fever.

Immediate rest in bed is entirely inconsistent with a journey by rail, by boat, or by coach. It frequently happens that the victim of enteric fever is taken ill at a distance from home. The first thing such an one wishes to do, when he begins to realize that his illness may prove serious, is to take the first train for home. To travel is one of the most injurious things a man with this disease can do. Probably no one with enteric fever ever took a journey who was not thereby made worse. When these patients refrain from travelling fewer of them will die.

Rest in bed, furthermore, does not embrace receiving company, transacting business, or conducting correspondence. All must be absolutely forbidden, for either is liable to increase and prolong the fever, or to cause its return, if undertaken too early during convalescence.

The patient must not leave the bed for any purpose whatever. He must not go to the water-closet. He must not get out of bed to urinate or defecate, but must use a bedpan. He must not leave the bed to get a drink, or to unlock a door, or to open a window, or to see if the sky is cloudy, or for any other one of the innumerable things which occur to his mind as necessary and desirable things to do.

This complete rest may be most certainly secured if the patient is early placed in the care of a well-trained and faithful nurse. If the case is a severe one, two nurses may be necessary.

The requisite condition of restfulness will be further promoted by the maintenance of an even and agreeable temperature, of an adequate supply of fresh air, and of a moderate amount of natural light. Occasional sponge-baths, also, frequently contribute greatly to the comfort of the patient. This uninterrupted rest in bed must be maintained until for a week the temperature, both morning and evening, has been below 99° F.

The second point to be considered has reference to diet. This must be such as will necessitate the least possible activity of the organs of digestion and assimilation. Of all food, by far the best in enteric fever is milk. The ordinary duration of the disease is so long that systematic feeding should be continued from the beginning to the end. Milk should be given at regular intervals in sufficient quantity, so that two quarts or more may be taken in twenty-four hours. If intestinal symptoms are severe the milk should be sterilized. If, for any reason, raw milk does not seem to agree with the patient it may be peptonized, or if a mild stimulant is desirable, it may be used in the form of wine-whey. A patient who cannot, or will not, take milk is exceedingly difficult to manage. If it is absolutely impossible to nourish him sufficiently with milk, recourse may be had to gruels and meat soups, broths and extracts. These, however, are less desirable than milk, because they are likely to ferment in the stomach and intestines with the production of gas, and because they tend to cause or to increase diarrhœa.

Liquid diet, preferably of milk, like rest in the recumbent position, must be maintained until, for a week, the temperature, during the entire day, has been below 99° F.

After this period has passed the patient may be allowed

[1] Read at the tenth annual meeting of the New York State Medical Association, in New York City, October 11, 1893.

to sit up for a short, and gradually increasing, time, each day. He may also be given a somewhat greater variety of food, beginning with gruels, soups, and broths, then eggs, a little later meat and bread, and last of all fruits and vegetables. In the meantime the temperature must be carefully watched, and if fever returns, constant rest in bed and a liquid diet must again be enforced.

The general treatment or management of the patient, as already outlined, is applicable to all cases of enteric fever, whether mild or severe, in male or female, in old or young. In fact this plan of treatment may wisely be followed in the management of any patient who has fever, whatever the cause of it may be. With regard to the rules which have been enumerated, there would be practically no difference of opinion among educated and sensible physicians.

Turning now from the hygienic and dietetic rules, which may be denominated the physiological side of the treatment, we pass to the more strictly therapeutical side of the subject. The measures which have been mentioned promote the normal physiological action of the various organs. Those which remain for discussion are employed to produce modifications of the disease process, or of those disorders of function which it has caused.

If one were to attempt to enumerate all the remedies which have been used with alleged benefit in this disease the list would be a wearisome one. On the other hand, some maintain that all drugs are injurious or useless, except as they are used with reference to some special symptom or complication. Osler, the clinical oracle of three great cities, teaches that enteric fever "is not to be treated by medicines." Other writers and teachers make equally discouraging statements. Very many believe that it is impossible to shorten the course of the disease or to diminish its severity by the administration of drugs. I shall venture to present a somewhat more optimistic view of the subject.

What therapeutical measures should be employed in the treatment of enteric fever? I reply: It depends entirely at what stage of the patient's illness you commence to treat him with reference to the fact that he has that disease. You may feel inclined to sneer at this statement and to say that it is puerile. But no one who has had much experience in the practice of medicine, if he looks at the matter without prejudice and in a rational way, can fail to realize that in the case of many a patient who has passed through the course of enteric fever, or has died before he reached the end of the disease, the physician in attendance has confidently and repeatedly asserted that the patient had malarial fever, or bilious fever, or gastric fever, or typho malarial fever, or some other disease, which he did not have. Perhaps before the disease has ended, or has destroyed his patient, he has modified his earlier opinion and has affirmed that the disease has run into enteric fever, or that enteric fever has developed in addition to the earlier condition. Of course a physician who said anything of this kind, and believed it, would not begin to treat his patient for enteric fever very early in the course of the disease. You will, I have no doubt, agree with me that such vacillating diagnosis is generally the fruit of ignorance or carelessness. Intelligent practitioners who are not so profoundly convinced of their own infallibility as to be unwilling to admit that they ever make a mistake in diagnosis, understand and will agree with me that, while enteric fever may commence insidiously, and may at first be difficult to distinguish with absolute certainty from other affections, it nevertheless, as a rule, runs a definite individual course, and is not, except in very exceptional instances, entangled with other inflammatory or febrile disorders, as a complication or sequel.

But it is not always the fault of the physician that he commences the treatment late in the course of the disease. Often the patient does not seek medical advice until the disease has been pursuing its course for days, or even weeks. Often, also, the patient, by choice or necessity, wisely or unwisely, passes from the care of one physician to that of another. To him who first sees the case, at the middle or end of the second week of the disease, very different indications for treatment appear from those which are usually observed at the beginning or middle of the first week.

Assuming that the physician sees the patient early in the course of the disease, and is alert to detect its nature, one of the first questions concerning the medicinal treatment which arises has reference to the use of cathartics.

The time was, fifteen or twenty years ago, when medical teachers almost unanimously condemned the use of cathartics in enteric fever. They protested against their use on the ground that, inasmuch as looseness of the bowels was one of the common symptoms, there was no necessity of causing any increased action of the bowels, and furthermore, that there was danger of increasing the inflammation of the intestinal mucous membrane and of producing hypercatharsis.

For the last ten or fifteen years there has been a tendency to regard one member of this class of remedies with less disfavor. During the last decade calomel has acquired considerable popularity in the treatment of enteric fever. A considerable proportion of practitioners now approve of giving one or more doses of this drug when the patient is seen early in the course of the disease, and when the diagnosis is made promptly. The best way to use calomel in this disease is to direct that the patient shall take from seven and one-half to ten grains of the drug every other day, until four doses have been taken. The earlier this treatment is commenced the more beneficial results will be observed from it. Occasionally it will cause some griping and a large number of loose movements. Under these circumstances it may be necessary to give an opiate to relieve the pain and to counteract the hypercatharsis. But, on the other hand, sometimes a dose of the size mentioned fails to produce any action of the bowels. In that case the patient should be directed to take one drachm of sulphate of magnesia, dissolved in water, every four hours, until the bowels move. If after four doses of calomel have been taken the bowels show a tendency to constipation, and the condition of the patient does not show positive improvement a fifth dose may be given with benefit.

Occasionally signs of commencing salivation are observed. These can generally be relieved by a gargle of chlorate of potash, dissolved in water.

The fact that unpleasant symptoms sometimes attend the use of calomel naturally suggests the criticism that it is wise not to prescribe the drug at all, if it is likely to occasion symptoms to combat which further treatment may be required, in addition to that which is necessary for the disease itself. In reply to this criticism it may be said that unpleasant and undesirable effects are of infrequent occurrence. As a rule these doses of calomel produce a few loose movements, with little or no griping, and very rarely give rise to any signs of salivation. On the contrary, I am able to testify to the positive beneficial effect of this treatment. It is my sincere conviction that used at the beginning of the illness calomel helps to shorten the duration of the disease and to diminish its severity.

The use of calomel in enteric fever is not a new thing. Formerly its employment was very general. The revival of its popularity was brought about, in part at least, by the teachings of Leibermeister, in Germany, and of Bartholow and Wilson, in America. A large number of practitioners now use it to a greater or less extent, and bear testimony to its utility. Some give smaller doses, as from one to five grains. Some give a single dose and others two or three. Others give minute doses, repeated several times during the day. In none of these ways is the same favorable action of the drug obtained as when the large doses of from seven and one-half to ten grains are given every forty-eight hours until four doses have been taken.

It will be difficult to explain positively just how the drug produces a favorable effect upon the disease. It is

certain that, as a rule, it removes a large amount of useless, and perhaps injurious, matter from the intestinal canal, including, in addition to fecal matter, bacteria ptomaïnes and leucomaïnes. It doubtless also relieves to some extent the congestion and inflammation of the intestinal mucous membrane. It very likely, either in its own form or modified chemically during its passage through the alimentary canal, acts as an antiseptic. It perhaps acts indirectly as an antiseptic by stimulating the secretion of the liver, and of the other glands which are concerned with the function of digestion. Possibly it has a sedative action on the entire nervous system. Certain it is that when used in connection with other remedies, which will be mentioned later, it reduces the temperature so that antipyretics are less urgently demanded, and diminishes the frequency and increases the force of the pulse, so that stimulants are less frequently required.

Rarely vomiting is a prominent symptom at the beginning of enteric fever. If present it may interfere with the favorable action of the calomel, or may seem to entirely contraindicate its use. But, as a rule, the calomel itself does not cause vomiting, or disturb the stomach in any way. On the contrary, it improves the condition of that organ, and, in fact, of the entire digestive system.

Aloes, podophyllum, and colocynth have justly been banished from the pharmacopœia of enteric fever. They are likely to aggravate the inflammation of the intestinal mucous membrane. Sulphate of magnesia may be used with much less danger, and in some cases with considerable benefit. High injections have been highly commended, and no doubt are sometimes of positive value in clearing the intestines of much useless and deleterious material.

Leaving now remedial measures which promote elimination, we pass next to a class of drugs which are prescribed chiefly with reference to the condition of the alimentary canal. The more prominent members of this group are the mineral acids, pepsin, quinine, salol, turpentine, nitrate of silver, carbolic acid or phenol, and iodine. Most, perhaps all, of these agents may fairly be classed as antiseptics, and for this reason without doubt have a distinct value.

The mineral acids in particular, and especially hydrochloric acid, have been for a long time in very general use. Their action, although feeble, is distinctly beneficial. They possess antiseptic qualities to a moderate degree. They also aid digestion and improve the condition of the stomach. Pepsin also assists digestion and promotes assimilation, and is frequently prescribed with benefit.

Quinine, so useful in many other conditions, is of very little use in enteric fever. It rarely, if ever, materially influences the course of the disease, or produces any important modification of its important symptoms. If there is any good reason for suspecting the presence of a malarial element a few large doses may be given at the beginning. Such cases are rare. In nine cases out of ten, to put the matter conservatively, the patient would be just as well off without quinine as with it. In every case, unless there is a distinct malarial complication, probably something else would do much more good. If no patient with enteric fever were ever given any quinine, probably there would be fewer deaths from the disease; because if physicians gave up the indiscriminate use of quinine they would be more alert to detect the real nature of diseases presented for treatment, there would not be so many mistakes in diagnosis, and fewer patients who were really suffering from enteric fever would be allowed to walk about while being treated for the results of alleged malarial poisoning.

Salol, although theoretically a valuable antiseptic, especially in affections of the stomach and intestines, has very little influence upon the course or the symptoms of enteric fever.

Turpentine is much used to relieve tympanites and to strengthen the nervous system. It is a valuable antiseptic, and exercises a favorable influence upon the processes of inflammation and ulceration, as they affect the intestinal mucous membrane.

The value of nitrate of silver in the treatment of inflammations of mucous membranes and in promoting the healing of ulcers is universally recognized. Many have testified to its great usefulness in enteric fever, and its employment certainly rests upon a reasonable basis.

Of late years carbolic acid, or phenol, and tincture of iodine have been considerably used, not only separately, but also in combination, and especially in connection with repeated large doses of calomel. This has been called the specific treatment, and has come into considerable popular favor through the writings of Bartholow and Wilson. Carbolic acid and iodine are valuable antiseptics. Both have a sedative action upon the stomach, and are held in some repute as remedies for the relief of nausea and vomiting. Of a mixture containing one drachm of carbolic acid and three drachms of tincture of iodine, four drops may be given, in a wineglassful of cold water, every four hours. Administered in this way, in connection with calomel, the duration of the disease may be shortened, the severity of the fever may be diminished, the tendency to diarrhœa is lessened, the condition of the digestive organs is improved, nervous symptoms do not become so severe, there is less danger of hemorrhage, and convalescence is hastened.

Many, of course, will say that they do not believe these assertions. Some will say that they have tried this method of treatment, and that it will not do what has been claimed. Others will say that they have seen it tried with no better results than were obtained from an expectant plan of treatment.

Time permits me to mention only briefly some of the conditions which must be observed in order to secure the most favorable results.

In the first place, the treatment must be commenced early. One might reasonably hesitate to begin the administration of large doses of calomel to a patient who had been sick with enteric fever for two weeks. Carbolic acid and iodine, however, may be advantageously prescribed at any time, and continued until the patient is convalescent. Whenever a patient is sick with enteric fever his physician ought to remember and suspect the possibility of the existence of that disease the first time he sees the patient. Unless he can with reasonable confidence exclude its existence, he may wisely commence the treatment with calomel. It may not be possible to make a correct diagnosis in every case the first time the patient is seen, but it is far safer to treat a doubtful case as if the patient had enteric fever than to treat him as if he had no serious disease, and permit him to remain out of bed.

An assertion of this purport, published in the *New York Medical Journal*, on August 6, 1892, provoked the criticism from an obscure practitioner, in a small town somewhere over in New Jersey, that "if one may not be correct every time it would seem wiser and better for one to be reasonably certain of being correct every time before he begins specific treatment of any kind."

I had endeavored to make it clear that one ought to commence active treatment even, in some cases, before a positive diagnosis has been made, because if it subsequently becomes certain that the disease is enteric fever, the patient has been greatly benefited, and if he has not that disease, he has not been injured in the slightest degree by the specific treatment.

Of course everyone recognizes that physicians differ a great deal in temperament. One man always has a diagnosis ready for every case, and never knows that he is wrong, or has made a mistake. Another is habitually uncertain about his diagnosis, and rarely feels quite sure that he is absolutely correct. Between these two extremes there are men who have all degrees of confidence in their own diagnostic ability, and whose faculties of differentiating diseases differ within equally wide limits.

The man who is always sure is often wrong, and always dangerous. The one who is cautious is frequently right and generally safe.

If a man intends to wait until he can make a positive diagnosis—in a case which may possibly prove to be enteric fever—before commencing treatment, he certainly owes to his patients the duty of perfecting his skill in diagnosis to the very highest possible degree, and of not following the teachings of such writers as encourage delay in making a diagnosis. It is a pity that any man should allow his patients to die, because he is not certain what the matter is, and because he is too obstinate to adopt a good plan of treatment as long as there is any uncertainty.

A second condition of success with the specific treatment is that it should not be abandoned prematurely. After it has been commenced it should be continued, in the absence of any important contraindication, until the patient is convalescent. If it is discontinued after a trial of only one or two days, very little benefit from it will be observed. If commenced early and followed up continuously, there is no other treatment now in use which gives so good results in enteric fever.

But there will always be some physicians who will not treat enteric fever in the way described. They will frequently—others, sometimes—find it necessary to resort to other therapeutic measures.

Hyperpyrexia is the most common indication for symptomatic treatment. At present, bathing, according to the method of Brand, is enjoying an enviable popularity as a method of reducing temperature and preventing complications. This may answer very well in hospitals, where it makes no particular difference whether any individual patient dies or gets well, and where there are conveniences for bathing and plenty of assistants. I venture, however, to predict with considerable confidence that this treatment will never be generally adopted in rural districts nor in private practice in cities.

Much testimony to its efficacy has been presented, but rarely has anyone taken the pains to describe in print the piteous and ineffectual appeals to be spared the distress of further Brand baths, of patients who, in spite of a continuance of the baths, died. Such cases never occupy a very conspicuous place in scientific reports on modern antipyretic treatment. The pathetic side of the story never appears in statistics.

Of the drugs which may be used to effect a reduction of temperature, antipyrine, acetanilide, and phenacetine are well known, and very useful. Given with moderation, and yet with adequate boldness, their effect carefully watched, and unfavorable action guarded against by the use of alcohol, they act with a reasonable degree of certainty, and undoubtedly have been the means of saving the lives of many persons who have suffered from enteric fever.

Stimulants, especially whiskey and brandy, are of great value in many cases. They should not be given as a matter of routine to every patient, and are rarely needed at the beginning of the disease. When the action of the heart begins to become weak, and symptoms relating to the nervous system become conspicuous, the administration of stimulants should be commenced. In some cases large and frequent doses will be found necessary.

If insomnia is a troublesome symptom, the bromide of sodium, morphine, or hydrate of chloral are useful. Their relative value is indicated by the order in which they have been named. Either one of the three may be given separately, or the bromide of sodium may be given with either of the other two, or all three may be prescribed together. These three drugs may also be used if there is much delirium, but morphine will generally be found to act less favorably than either of the others, which, moreover, may often be used together very advantageously. Their action should be supplemented by cold applications to the head.

When diarrhœa is excessive and persistent, bismuth and morphine will in most cases be found useful. If intestinal hemorrhage occurs, turpentine or ergot will prove most valuable. Their action should be aided and supplemented by the external use of cold compresses.

In conclusion, the following rules may be formulated. They constitute a safe guide in the treatment of enteric fever:

1. Never overlook the disease or forget the possibility of its occurrence in any patient who seeks medical advice.

2. If the symptoms indicate that the patient may be suffering from enteric fever, begin to treat him at once, and follow up the treatment until it is certain that he has not that disease, or until he is well.

3. Commence the treatment by putting the patient to bed and keeping him there, by forbidding all solid food—limiting him if possible to milk—and by prohibiting reading, writing, and conversation.

4. Commence at the same time the so-called specific treatment, embracing the use of repeated large doses of calomel, in connection with carbolic acid and tincture of iodine. Commence this medicinal treatment early, and continue it until the patient is convalescent.

5. Do not permit the patient to abandon the recumbent position, a liquid diet, and absolute quietude until for a week the temperature, at no time during the twenty-four hours, has been above 99° F.

6. Do not condemn the specific treatment until you have tried it in the way described, and do not attempt to form an opinion in regard to it until you have tried it in a series of cases, and have carefully observed its effects, and compared them with those obtained by other methods of treatment.

CORRECTION OF DEFORMITIES OF THE ORAL REGION.

By ALBERT WESTLAKE, D.D.S.,

CLINICAL LECTURER, NEW YORK COLLEGE OF DENTISTRY, ETC.

A WELL-KNOWN and recent authority on the deformities of the oral region says: "The attempt at the replacement of a nose may be regarded as exceptional, for the reason that it is so conspicuous an organ that the appearance is of more consequence than utility. There is no organ of the entire economy the loss of which creates so hideous a deformity as the nose, nor is the successful prosthetic restoration of any organ so difficult."

Anticipating the interest that would be excited among the medical and surgical profession by a successful attempt to overcome such a deformity, I have had plates prepared from photographs, "before and after," and present them in this issue, together with an interesting ear case and an illustrated report of a practical dental device to overcome the deformity attending the extirpation of left half of inferior maxilla.

The history of Exhibit No. 1, artificial nose, is as follows:

In 1870 Mrs. X——, now aged sixty three, through the indiscretion of her husband, contracted syphilis. She first complained of soreness in the region of the nose and malar bones, and of an itching and pain in the hard palate. Subsequently the turbinated, vomer, nasal, and palate bones were removed. The appearance after twenty years is represented in Figs. 1 and 2, the parts, at present, being in a normal condition. After giving the mouth proper dental treatment by thoroughly cleansing and filling the root canals of remaining three teeth, I fitted gold cap-crowns over each tooth and then soldered them together, making a perfect union. They were carefully cemented to the teeth, and being closely fitted under the gingival margin of the gum, were comfortable and perfectly aseptic. I next fitted an upper denture, which closed the opening in the hard palate and articulated naturally with the lower teeth.

In the adjustment of a nose I followed a plan I had heretofore used in such cases. First taking a plaster cast of the head (and in the case of this patient being aided by an old photograph), I succeeded, by a careful appreci-

ation of the general facial contour in preparing a preliminary nose in wax. This is made as near as possible in color to the complexion, so as to secure the proper blending of shade and expression. When satisfactory to my patient and myself, I made an aluminum cast, about a line in thickness, and in weight not exceeding four pennyweights. Over this I painted the flesh enamel, being a preparation of wax, gum-arabic, gutta-percha, etc., which resembles closely the translucency of flesh, and is not affected by ordinary thermal changes. After the nose was thus prepared and adjusted to the face, I was fortunate in securing the services of Mr. Constant Thys, the artist in charge of the Eden Musée, who imparted the life-like appearance, blending with the complexion so closely, even to the wrinkles, pores, and veins, as to challenge detection.

The main difficulty was then presented in securing the nose to the face. I overcame this, after several trials, by fastening a bar of gold and platina to the inner ridge of the nose, and passing it down at a carefully studied angle through the centre of the artificial denture. Various devices were tried to secure the bar after passing through the plate. I found that although a nut and a triple thread would work well when I used the forceps or a specially prepared holder, yet the patient found it exceedingly awkward. I also rejected the plan of securing the bar by a spring-nut similar to those used in French clocks, fearing that if it suddenly loosened the patient would swallow it.

I finally decided and adopted, much to the pleasure and comfort of my patient, the simple extension on the plan of a blade and spring in a pocket-knife. As the nose was placed on the face and the bar passed through the hole in the plate, she could, by simply pressing the extension, spring it tightly in a groove in the plate, and as easily remove it.

The nose when adjusted is represented in Fig. 3. The only apparent joining that can be noticed is immediately below the junction of the eyebrows, and this is not visible when the patient wears glasses. Spectacles are not necessary to its stability. In masticating there is no movement of the nose.

As shown in Fig. 1, there was partial destruction of the soft palate. As our authorities state, and as we well know, this organ is an important factor in the perfection of human speech. The voice, as it issues from the larynx, is modified in tone and character, and interrupted in its passage by certain organs, the most important being the velum palati. This acts as a curtain, directing all the sound at times through the mouth, and again, combined or entirely, through the nasal passages, by being in firm contact with the dorsum of the tongue. The soft palate, in conjunction with the muscular wall of the pharynx, must be under active control to secure the purity of speech. A certain indistinctness of utterance follows where the soft palate is deficient or deformed (as often found after operations of staphylorrhaphy, when the newly formed septum is rigid, tense, and deficient in length), or the pharyngeal walls are paralyzed or inactive.

Although the velum lost in this case is not very extensive, requiring only an obturator less in size than a pigeon's egg, yet I was unable to fit it with comfort, owing to the gagging or apparently suffocating sensation it caused. The restoration of speech to this patient is remarkable. The improvement is marked in the vowels and diphthongs, because the plate covering the aperture in the hard palate allows the resonance in the buccal cavity —where all vowels are made—and closes the abnormal communication with the nasal cavity. The physiological action of the nares and nostrils is, of course, important for the production of purity in speech, and as this nose is mechanical, there remains imperfect sounds which practice will hardly overcome.

The patient, at my suggestion, has commenced lessons in elocution. I have advised the study of the French or some foreign language, mainly to divert the mind from the forced habit of speaking her own vernacular badly.

Professor J. Bond Litting, at the meeting of the New York Odontological Society, said: "I had the pleasure of seeing the finished case mentioned by Dr. Westlake, and I must say that the appearance and adaptation were as complete as I have ever seen. In fact, I do not doubt but that the party might walk into the room and a casual observer would not notice that the nose was artificial. The attachment was complete in the fact that there was no movement during mastication, it being attached to the plate, and the plate being fastened to the teeth, so it would hold perfectly firm. That the tissues may yield in the course of time I have no doubt; but the attachment that Dr. Westlake has with the spring, which will

Fig. 1.—Exhibit of model of jaw. Fig. 2.—Exhibit from photograph before operation. Fig. 3.—Exhibit from photograph after operation.

shut down closely, so as to hold the rod which fastens through the plate, I think will enable the patient to wear it a considerable length of time without alteration."

Fig. 4 represents a remarkable congenital deformity of the ear. The patient is a well-developed lad, twelve years of age, and the ear of the right side is beautifully formed.

During the early spring Dr. Charles McBurney made a skilful operation, opening through the stub close to the skull, providing a slit half an inch long and very strong. A skeleton frame was then made of aluminum, with platinum and gold spring, and an ear (see Fig. 5), an exact copy of the opposite one, composed of similar enamel material used in the nose case, was then cast. The piece of gold and

Fig. 4.

platinum marked A, was passed through the slit, and as the ear was pressed it locked tightly. To prevent too great a pressure on the stub, I advised the use of an adhesive cement about the edges of the ear, which held it closely to the skin, so no junction was apparent. When it was to be removed a small point posteriorly was pressed which unlocked the spring. There was no auditory canal, the patient hearing on that side by contact only.

Fig. 6 represents the dental aspect of the inferior maxilla immediately preceding its excision in March, 1891. About one year previously the patient had first noticed a small lump on the outer side of the left inferior alveolar process, opposite the second molar. The enlargement had grown rapidly, especially during the last few months, and was extending posteriorly, accompanied by sensation of throbbing and itching. The tumor was about as large as an egg, was hard, painless, ulcerated on upper surface, and bulging chiefly outward. It extended nearly to the angle. The second molar was pushed far inward. In the left submaxillary triangle an enlarged lymphatic, nearly as large as a bean, was noted.

Fig. 5.

Dr. Charles McBurney, who had charge of the case, explained to me that he was desirous of finding some way to overcome the great deformity which usually results from such an extensive loss of tissue. I thereupon obtained correct plaster representations of the teeth and their articulating relations, and constructed an interdental splint which was fitted and kept in readiness to be inserted immediately after the operation, to retain the remainder of the maxilla in normal position during the process of healing.

On March 21st, Dr. McBurney operated with a view to the removal of nearly the entire left half of the inferior maxilla. An incision was first made just beneath the lower edge of the jaw, extending from the median line to the angle. This incision was supplemented by a vertical one extending from the angle upward along the posterior border of the ramus as far as the middle of the lobe of the ear. The cheek and superficial soft parts were dissected from the outer surface of the bone, and the muscles, etc., from the inner surface as far as the mucous membrane, keeping well off from the tumor. The mucous membrane was then divided, the left first bicuspid extracted, and the inferior maxilla sawed through at that point. The end of the left section was then

Fig. 6.

seized and dislocated outward, the pterygoid muscles were divided, and the bone removed at the articulation.

The splint was adjusted before the patient left the operating table, to illustrate its application in view of the surgeons and students present. The splint was then removed until recovery from the influence of the anæsthetic. Thereafter it was kept in position, except during necessary irrigations, until the patient was dismissed as cured.

Fig. 7.

It was a happy inspiration that prompted the preliminary construction of this appliance, as the recovery of the patient was more rapid than ordinary, the splint fitting accurately and keeping the articulation of the remaining teeth continuously normal. On March 30th the sutures were removed, and on April 16th all the dressings were discontinued by reason of the complete healing of the parts. The microscopical examination of the

tumor demonstrated it to be a spindle-celled osteo-sarcoma.

Figs. 7 and 8 represent the resulting deformity. Accurate plaster impressions of all the teeth were obtained, and their articulations were correctly represented by the models. Silk ligatures were attached to each of the remaining inferior teeth, and the ligatures were successively caught on the hook of a "cotton scale" graduated to

Fig. 8.

register ounces and their fractions. By traction on the scale against the retracting or extensive action of all the muscles of the dismembered jaw, the amount of force requisite to overcome the drooping tendency of the jaw (see Figs. 7 and 8) was ascertained. The maximum distributed downward, or mouth-opening force of which the patient was capable, was registered at four pounds and two ounces. The involuntary or habitual tendency of the

Fig. 9.

jaw to drop equalled an average force of a little less than one pound.

An examination of all the accessible text-books disclosed no measurements of the dynamic powers of this group of muscles under like circumstances, and hence I infer the novelty of both theory and practice in the course and construction adopted in this case.

The first procedure was to fit and adjust upper and lower electro-metallic plates provided with retracting spiral springs of gold wire, but this contrivance was abandoned as being too bulky and lacking sufficient tensile strength in the springs to draw the jaw into position and retain it during the process of mastication. Several devices were then tried in various ways, including an inclined plane of steel. The final plan was to make for the superior left molars two gold cap-crowns, which were soldered together, and at their buccal junction there was soldered a stiff and knobbed gold wire projecting downward at an angle of about forty-five degrees. A gold cap-crown was also made for the inferior left cuspid, and to the labial surface of the crown was soldered another short-knobbed gold wire extending in the direction of normal occlusion. A steel spring similar to that used in the flexible connection of the dental engine with the hand-piece was repeatedly cut off and tested, until the required resilient power was found in a length of thirty-two coils. This spring was electro-plated, and the looped ends slipped over the knobs on the crowns, which had been previously cemented on to the molars and cuspid, respectively. The action of the device was very gratifying, for when the patient closed her mouth the remaining teeth were brought into normal apposition, as represented in Fig. 9, and were so retained by the action of the spring. The great mental depression experienced by the patient in consequence of the awkward position of the jaw (see Figs. 7 and 8) was immediately relieved, and both mastication and speech made easy.[1] The spring could be removed at will by the patient, and as occasion required a new one was substituted without displacing the cap crowns, which, being accurately fitted and highly polished, are perfectly aseptic.

As was confidently anticipated as the result of the splint and mechanical expedient, the remaining operative muscles were strengthened, so that within six weeks after the operation the patient had nearly overcome the retrograde tendency of the jaw, and upon removal of the spring could articulate the teeth. About six months after this the muscles were sufficiently strong for the mastication of meat, etc., without artificial aid, and I then removed the spurs and spring, and fitted a metal plate carrying a vulcanite "plumper," highly polished and fitted to fill out the lower integuments so well as to render the detection, at present time, of an operation only by a faint scar beneath the artificial ramus.

The precautionary measure in having in readiness the interdental splint supplemented by the spring attachments, together with the intelligent co-operation of the patient in training the muscles, have combined to secure the present success.

The First French Ovariotomist.—Ovariotomy was, it appears, performed for the first time in France by Dr. Voycikowski, on April 28, 1844. The patient was a Madame Reptumar, of Montfort, who died only a few years ago. Voycikowski, who was of Polish extraction, was born in 1810, took his doctor's degree at Montpellier in 1840, and practised his profession at Quingey, in the department of Doubs, till 1861, when he migrated to Paris. He died at Dijon, in very poor circumstances, in 1882. Dr. E. Rolland, of Toulouse, has taken the initiative in starting a subscription to raise funds for the removal of Voycikowski's remains to the new cemetery at Dijon, and for the education of his children.

Guaiacol Salts have, of late, been tried in cases of tuberculosis. The guaiacol carbonate or the guaiacol benzoate may be advantageously substituted for the preparations of creosote. Dose, from three to five grains up to point of tolerance.—Solis-Cohen.

[1] I have noted as an interesting physiological feature of all such surgical operations coming under my care, that the patient, for some period subsequent to the operation, complains of considerable loss of memory.

A MURAL DERMOID CYST OF THE UTERUS.

By W. W. STEWART, M.D.,

COLUMBUS, GA.

(Illustrated by Author.)

Before reporting this case I will give a brief *résumé* of the theories of the formation of dermoid cysts, their pathology, and their frequency.

Those theories, which have been advanced by different pathologists, are as follows: Extra-uterine pregnancy; diplogenesis by fœtal inclusion; plastic heterotopia (Lambert); pathogenesis; theory of impaction (Verneuil).

Extra-uterine pregnancy can well be excluded, as many instances are on record where they appear in the male as well as the female, and in numerous instances in children. Also their appearance in different portions of the body far removed from genital tract.

Diplogenesis by fœtal inclusion has a cloud thrown upon its verity by the large number of teeth often found in many cases.

Autenreith describes a case out of which three hundred teeth were taken, and more remained.

Schnabet reports a case where one hundred teeth were removed. Planquet, one from which three hundred were taken.

Plastic heterotopia is more a name than a description of a pathological process.

Pathogenesis, which considers their formation due to proliferation of germinating epithelial cells, is not satisfactory, as it fails to account for the presence of similar growths in other parts of the body where there is no epithelium.

This brings us to the true theory, at least the most tenable one, that of impaction, the theory of Verneuil.

According to him, a portion of the blastoderm is forced by pressure into the tissues, there remaining dormant for a while, afterward developing, thus producing by its growth erratic development of normal tissues.

Lannelongue classifies another formation as fœtal cysts where fœtal remains are found, and considers them as a combination of cyst and double monster.

The cyst-wall is usually composed of many component parts—as unstriped muscular fibres, epithelial cells, fibrous tissue, mucous membrane, structures much resembling true skin, containing hair-follicles, sweat-glands, and nerve-endings. Embedded in its walls are found bones of various shapes and sizes, teeth and hair, in greater or less abundance, growing from puckered ridges or protruding masses of tissues resembling true skin or mucous membrane.

In the cyst-cavity there has been found, in one instance, a body much resembling the human eye in minute structure. Also nerve-tissue, gray matter, balls of hair and nails. Olshausen collected statistics of 2,275 cases coming from a series of ovariotomies performed by Spencer Wells, Keith, Schröder, Krossowiski, A. Martin, Billroth, C. v. Braun, Esmarch, Dohrn, and himself. Out of this number there were only 80 dermoid cysts, 3.5 per cent. This shows the rarity of their development.

The case which I report is, as far as I can determine by my researches into the literature of the subject, the only case where the dermoid cyst was of the uterus. In the large majority of cases they are of the ovaries. Cases are reported where they have existed in the brain, lungs, floor of the mouth, orbit, mediastinum, mesentery, and testicles.

The case to which I would now invite your attention is that of Mrs. W——, aged thirty-one; married ten years; four children; brunette, five feet three in height; weight, when in health, one hundred and thirty-six pounds. Was brought to me on September 4, 1893, by Dr. W. D. Williams, of Cataula, Ga., under whose care she had been. He brought her to me for operation, having diagnosed an abdominal tumor, the character of which he was uncertain.

History.—When a child, was not strong; could not play as long nor as violently as other children, violent exercise producing cramps in the stomach. She continued in about the same condition till puberty. Her menstrual flow appeared in her thirteenth year, causing her much pain, bearing down in character; this condition remaining till one month after marriage, when she became pregnant. At the age of twenty-one she gave birth to her first child, labor lasting eight hours; normal in character. Eighteen months thereafter became pregnant again, labor lasting three hours, no complications. Again, after thirty-three months, became pregnant, labor lasting two hours, normal in character. Thirty months after last labor fourth child was born. Easy labor, lasting one and one-half hour. Did well till seventh day, when she was taken with one of her old attacks of cramps in lower portion of stomach, unusually severe in character, causing so much pain that her attending physician was compelled to remain all night, administering opiates. After this she had some fever lasting for several weeks. All menstrual pains ceased after birth of first child.

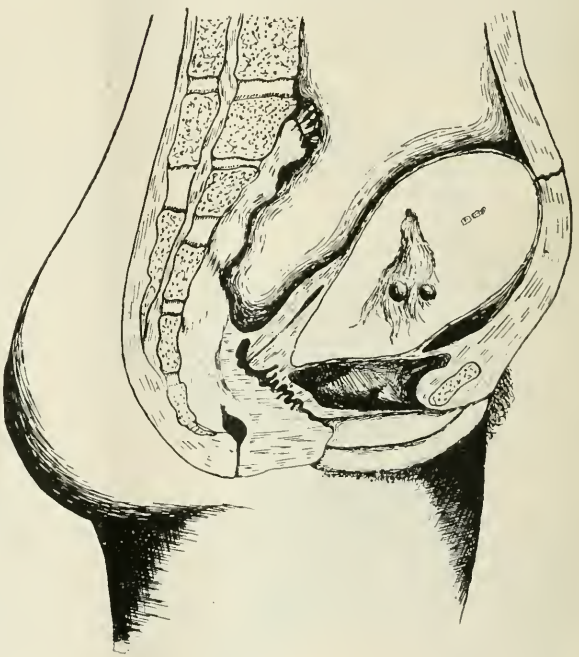

Fig. 1.

On March 20, 1893, she developed typhoid fever which continued for ten weeks, leaving her much prostrated. Fever continued after all typhoid symptoms disappeared, it then assuming a septic chart ranging from 99° F. to 103° F.; night-sweats profuse. She then began to notice an enlargement of her stomach. Thinking she was pregnant, consulted her physician on the subject, who for a while thought it a normal pregnancy.

On May 30th she had a uterine hemorrhage which was controlled by the administration of ergot. This reappeared every twenty-eight days, and was treated in the same manner till August 21st.

August 25th, noticed a soft spot three inches below

umbilicus, in median line. This point had been the focus of oft recurring pains since enlargement of stomach began. Pains were rhythmical in character, causing her to fear an oncoming abortion.

On August 26th it was examined by Dr. Williams. Detecting fluctuation he opened it by a small incision extending only through the skin. It discharged a quantity of foul-smelling pus mixed with white flocculi resembling closely vernix caseosa. The fistulous opening thus formed continued to discharge small quantities of pus. No more rhythmical pains were noticed after incision was made.

On September 4th I made a careful examination which

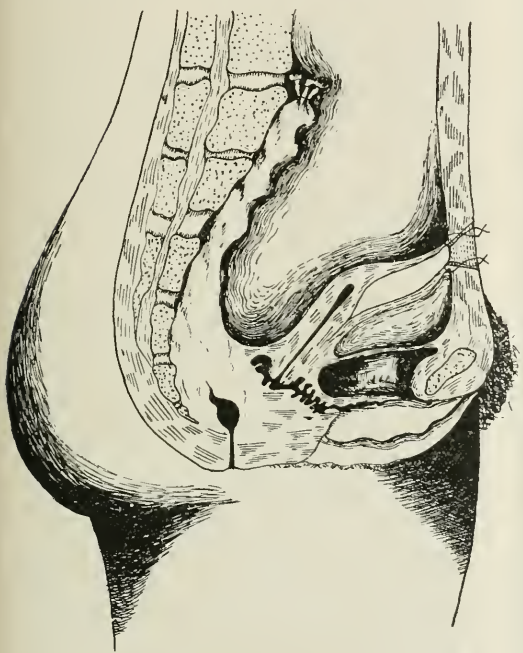

Fig. 2.

elicited the following facts: Vagina elongated, otherwise normal. Cervix drawn backward and upward, resting in median line, normal in consistency and size. Uterus could not be isolated from abdominal tumor, which was about the size of a man's head, and adherent to abdominal wall in median line. Cul-de sac of Douglas empty. Laterally, structure seemed to be in normal condition. Abdominal walls were tense, not permitting tubes or ovaries to be made out. Externally, the tumor had exactly the feel of a pregnant uterus. Uterine contractions could be detected by bimanual palpation. Pulse, 100; temperature, 102½° F. Cachexia marked. Face covered with brown blotches. Body emaciated. Urine normal.

Diagnosis.—Suppurating mural tumor of the uterus, the character of which could only be detected by exploratory incision. The condition, as revealed by examination, is depicted in Fig. 1.

Temperature remained between 100½° F. and 102½° F., and pulse between 100 to 120, from September 4th to 11th, the day of operation.

After preparatory treatment, assisted by Dr. George J. Grimes and Dr. McD. Blanchard, and in the presence of Drs. Williams, Tucker, and Pitman the operation was performed. An incision three inches in length, in median line, the fistulous tract marking its upper extremity, was made through superficial structures and down to peritoneum, which was drawn up with mouse toothed forceps and incised, which brought into view a dark-reddish body (the distended uterus). This in turn was caught up by tenaculums and sutured to abdominal walls, to which it was already adherent, and incised. Immediately there gushed out about one quart of thick and extremely offensive flocculent pus. The fingers were then introduced into sac, and a mass of matted hair, in balls, with long wisps connecting them, was removed. On further investigation three teeth were found embedded in left wall of abscess cavity.

It was evidenced, by palpation and rhythmical contractions, that the sac was a distended uterine wall. And from the deep implantation of the teeth, probably penetrating through the uterine wall, and the highly septic condition of the sac, it was deemed best to let them remain as they were.

Sac was then well irrigated with boiled water and packed with iodoform gauze, it requiring five ounces to fill it. At next dressing, two days after, sac was well washed with boiled water, then with peroxide of hydrogen, full strength, then packed with iodoform gauze. At this dressing it would contain only one ounce of gauze.

The same dressing was continued every second day till sixth day, when a solution tincture of iodine the color of sherry wine was substituted for peroxide of hydrogen.

The rapid contraction of sac continued. On the eighth day would contain only one ounce of water. Pus almost disappeared.

The rapid contraction of the sac further proved the nature of the sac-wall.

Temperature after operation fell to normal and remained so. Pulse to 80, regular and much fuller. Remainder of recovery uneventful.

STATIC ELECTRICITY IN CUTANEOUS AFFECTIONS.

By S. H. MONELL, M.D.,

NEW YORK.

THE literature of static electricity does not appear to indicate that it has hitherto rendered any important service in the treatment of skin diseases. The "Index Medicus," the "Annual of the Universal Medical Sciences," and late editions of dermatological text-books are equally silent upon this use of the static machine. Crocker disposes of the whole subject of electricity (apart from electrolysis) in a short paragraph, viz., "The galvanic current has been occasionally used to relieve the pains of herpes zoster and for pruritus, but it and the faradic current have found but small employment hitherto in dermatology, except in Raynaud's disease, in which galvanism has been of some service." A general survey discovers other writers who give more credit to these currents than Crocker, but none appear to employ the static machine in reported competition with "lotions, ointments, dusting powders, tar, and arsenic." It is therefore to be presumed that a report of an attempt to extend the therapeutic properties of the static current into a new field of usefulness will enlist the interest both of dermatologists and the friends of medical electricity. Last spring a young man came to my office who had been suffering for six months from furunculosis. History and examination failed to disclose any apparent cause. During the period of his affliction he had found a change of climate, rest, dieting, sulphur, sulphide of calcium, alteratives, tonics, etc., equally unavailing. He had been in other and very competent hands for treatment, but did not obtain relief. There finally being no indicated drug left untried in his case, he was placed upon my static platform and its influence tested. An improvement at once began. A few sittings were given, extending over a couple of weeks, when he was discharged without a single boil, and he has had none since. Shortly after this date I treated a case of herpes zoster in the same way. The burning and itching were immediately les-

sened, and the case rapidly went on to complete relief. A peculiar case of chronic cutaneous hyperæsthesia was next treated with static electricity.

Case I.—The subject was a male, aged sixty-two. The disordered sensation was limited to the surface of his body, his upper and lower extremities being entirely free. It had annoyed him persistently for thirty years, and during the past eight or ten years it had forced him to undress and retire to bed about four o'clock P.M. daily, as the weight and contact of his clothes became unendurable. In other respects he was perfectly able to attend to business. Firm pressure was fully tolerated, but slight contact or a current of cold air caused an extreme aggravation. This condition pursued the even tenor of its way undisturbed by season, climate, diet, constitutional state, outward applications, or internal remedies. I devoted more than a year to attempts to relieve him by drugs, but with no better fortune than my many medical predecessors from whom I had inherited the case. Static electricity was then employed. Its effect was grateful. In a week he was remaining dressed until seven or eight o'clock in the evening. In two weeks the relief was such that he was no longer compelled to retire before the usual hour. He continued this treatment for a month and a half, during which he received twelve treatments at my office, and then left the city for the summer. I am informed that his improvement is still maintained, and that he has a satisfactory degree of comfort.

But it is in eczema that I have been most delighted with the effects of static electricity. No matter how chronic, how thickened, obdurate, or extensive the case may be, it will find its master in skilfully directed static electricity. Books teem with prescriptions for this protean disease, a sure sign of the uncertainty of medical treatment. In fact, it is usually stated at the end of an interminable list of drugs that "there is no specific for eczema." Before proceeding to the citation of cases it will be interesting to every student of the physiological action of static electricity to hark a moment to the causes of this disease. "Of the predisposing causes the most universal and active is some disturbance of digestion, constipation, mal-assimilation, perverted nutrition, derangement of the liver. At other times the kidneys are at fault. Chlorosis and anæmia, uterine disorders and the menopause, are active factors. The strumous diathesis, derangements of the nervous system, rheumatism, gout, and varicose veins are other predisposing causes." Every word of this etiology sounds like a trumpet-call for static electricity. Perversions of nutrition and nerve action are especially amenable to its influence. It is a regulator of the body functions. I believe that skilfully directed static administrations—and particularly in the form of "potential interruption" lately introduced by me, and now briefly known as "the Monell Method"—constitute the most effective nutritional stimulant known to medicine; and the permanency of its effects indicates that it is far more than a mere stimulant. In eczema the results of static electricity are particularly happy. I have treated a number of cases successfully. All surface irritation and itching has been speedily allayed. In one case the first treatment gave entire relief for forty-eight hours. Moist eczemas become dry, chronic squamous eczemas, and indurated, thickened surfaces, scale off, healthier skin appears, and the transition to normal cuticle goes rapidly on under the influence of the tonic static stimulation. A few examples may be cited.

Case I.—Male, aged forty-five. Had syphilis twenty-five years ago, with recent tertiary lesions. One year ago had pruritus ani. By diligent scratching he had developed an eczematous condition of the entire inter-natal region and scrotum, with three large irritable ulcers and fetid suppuration. Pain prevented him from walking except very slowly, and for six months he had been unable to sit on a chair. Sleep was badly broken, and he presented a pitiable condition. Treatment was begun with the usual remedies, but three days later (September 7th) he appeared, suffering such intense pain and distress that I determined to test the efficacy of static electricity. It fulfilled my expectations completely. Two days later he again called and requested me to give him more static electricity, as it had afforded him his first real relief. He could now walk quite briskly with scarcely any pain on motion, and the fetor had been entirely removed. By September 14th suppuration ceased, the ulcers were healing, and the itch and pain were controlled. September 16th, ulcers scabbed over, can sit now with comfort and walk easily. September 20th, all pain gone, ulcers reduced to one-half original size, general condition greatly improved. Can run for a street car, for the first time in a year. September 25th, nearly well. September 29th, presented himself to report entire recovery, and treatment was stopped.

Case II.—Male, aged forty-seven. Bridge-builder; often stands in salt-water all day. Had eczema two years. Location chiefly forehead, nape of neck, bend of elbows, and both lower extremities. From knees to ankles the entire surface was affected, and ankle-joints were swollen so he could not wear shoes. Paroxysms of itching were severe. Treatment was begun with galvanism and continued for two weeks, with some relief to his intense pain, but with slight general improvement. Static administrations were substituted on September 4th, and at first were applied daily. On the 14th he was able to discard sandals and resume shoes, walked without pain, slept comfortably, and each treatment controlled the itching till he came again. His forehead now appeared normally free from eruption. By September 28th he appeared nearly well, the lower third of extremities alone showing any traces of the affection. Reported himself free from all surface irritation, and did not return for further treatment. He had nine static applications altogether.

Case III.—Female, aged thirty-eight; married. Oval patch of squamous eczema on left breast, one inch above nipple, two inches long by one and a half wide. Has been constantly present for fifteen years, changing but little in its condition and resisting such treatment as various physicians gave it. When first seen by the writer, on September 21st, it was very red, rough, and itchy, and covered with a thick scaly surface. Static applications were made on September 21st, 26th, 28th, October 3d, 9th, 16th, and 23d. Between sittings she has almost entire relief from itching; the patch is already reduced one-half in size, and normal cuticle is beginning to appear in places. This improvement in a lesion existing for fifteen years has been very gratifying to the patient; but it can hardly be questioned that the static current, which is so powerful to regulate organic functions and improve the nutrition of muscles and nerves, is equally able to regulate the functions and improve the nutrition of the skin. Other cases could be cited, but the foregoing are sufficient for the purposes of this article. In every lesion of the skin where stimulation of local or general nutrition is indicated, static electricity can be made an important factor in the treatment.

It also seems probable that further experience will prove static electricity to be one of the most potent of anti-pruritics. Carbolic acid has won its fame as "the opium of the skin." Its sedative property is invaluable, though the ease it affords is often brief. The relief of all painful, pruritic, and neurotic symptoms associated with the cases of skin disease which I have treated with the static machine has, however, seemed to be prompt and lasting. In the itching of eczema, where a full week has elapsed between two séances, the distress has been controlled during even this long interval, and in no case treated by me has this symptom continued as an annoyance. I will report one case which may be considered typical, viz., chronic pruritus of the scrotum, existing since 1883. The victim of this exasperating neurosis has been under my close personal observation for several years, and I had made fruitless attempts to cure him. From 1883 to 1890 he had made the most careful, painstaking, and persistent search for a means of relief. His

efforts had received the able assistance of Dr. Bulkley, Dr. Keyes, and a number of other excellent dermatologists in this and other cities. He had tested the whole art of medicine, and finding in it no lasting benefit he abandoned all hope of being cured. The itching in this case was unusually severe, even by day, and the paroxysms on undressing and during the night interfered greatly with sleep and impaired his general health. I began the administration of static electricity with less confidence than in my cases of eczema, and at first it made no impression upon the trouble, but on the third visit to my office he reported a slight improvement. The gain has slowly and steadily continued. He is at length emancipated from the nightly applications of lotions and sedative ointments. The frenzied paroxysm upon undressing is absent, and such itching as at times occurs is mild and tolerable compared with the suffering of the past. It seems reasonable to expect an ultimate cure, the main uncertainty arising from the fact that he has obtained so great a degree of comfort that he does not come regularly for treatment.

665 Lexington Avenue.

KEY-NOTES TO THE TREATMENT OF CONSUMPTION.

By E. C. ATKINS, M.D.,

COLORADO SPRINGS, COL.

In these days when hundreds of invalids are seeking our mountainous elevations and sunny climate for the cure of pulmonary disease, and when physicians from all over the world are sending such cases here for treatment, it is hardly necessary to enlarge upon the advantages of climatic treatment in this most intractable disease. That many such cases recover here is too well known for argument. Looking back over four years of personal experience with the disease, and of careful study of my own and hundreds of other similar cases, certain factors stand out prominently as essential and vital points to be observed in treating this disease, and which, if neglected, too often end in failure and death.

I am convinced that too much reliance is being placed upon medicine and the unaided climate, and that vital principles of nutrition, hygiene, and the common laws of health are being utterly neglected. A blind and implicit trust is placed in the climate, while the patient is allowed to violate all the laws of health, which, under any other circumstances, would have been taken into account.

No one denies that, whatever the original cause of phthisis, whether it be the tubercle bacillus, as most of us think, or something else, once established it is a wasting disease, with failure of all the nutritive functions as prominent symptoms in most cases.

We have sought in vain for medicines that will reach the foundation of this disturbance, and the ever increasing number is evidence of the futility of all. Cod-liver oil, so much relied upon by many, does more harm than good; it disorders the digestion, and, as often as not, passes the bowels unchanged. Creosote, a recent favorite, if it has any beneficial action, seems to have its effect indirectly through its action on the digestion. Malt, hypophosphites, and other tonics and nutritives act indirectly as aids to nutrition. The drug that has any specific action on the disease itself has yet to be found, unless (oh! shades of our ancestors!) the "animal juices," "pulmonine," shall prove to be that potent agency.

I have noticed that the cases that recover here are either the incipient hemorrhagic ones, or, if more advanced, are those that have a good stomach and a vigorous appetite, who are able to digest and assimilate a sufficient amount of nitrogenous food to supply the waste and build up the diseased tissue. Without such a stomach neither this nor any other climate can cure the disease, unless the digestive powers can be roused to do their duty. This they can be made to do, but not with medicine. The bitter tonics, the nutritives, alcoholics, all fail us in our time of need.

The climate of Colorado Springs will accomplish a cure if it has a fair chance, but it cannot do so without the proper materials to work with. Nature's laws and her mute appeals for help must not be entirely disregarded if good results are to be looked for. I wish to call attention to a few points which I feel will appeal to every thoughtful physician.

The Stomach.—If, as is the case with many, it will not work, it must and can be made to do so. It is absolutely necessary that an abundance of nitrogenous food should be digested and assimilated, for it is to this food alone that we must look for material to restore the diseased tissues. The appetite must be roused to the point of taking meat with a relish. This can be done even in those cases where there is great disgust for food, and where, apparently, no meat is digested.

Let us suppose a case. A patient in the first or second stage comes here for treatment. If he improves, well and good. If not, there is a reason for it, and with careful examination that reason will be found in some grave disturbance of the digestive and assimilative functions. It may manifest itself as a slight impairment of appetite, or there may be entire loss of appetite, vomiting after eating, and colliquative diarrhœa. His stomach heaves at the thought of meat. We find him eating no solid food—a little soup, milk, fruit, mustard pickles, and the like.

How much building material can be got out of a diet of that kind! How can climate work a cure when there is no material to work with! The lung lesion may be such that the patient ought to recover, but can any sane man expect him to do so while he starves himself to death on a diet in which the tissue-building foods are conspicuous by their absence?

Such a case dies from exhaustion induced by the lack of proper food rather than from the disease of the lung. Such a condition gives all the advantage to the disease, and it never fails to make the most of it. Now what can we do if the patient will not eat? Shall we sit calmly by and wait for the climate to act under impossible conditions till the patient dies for the lack of a little common-sense guidance? Such a case, even in the late second stage, can be made to respond to treatment, and to eat meat with abundant relish.

The day is passed when such advice as "eat anything you want, and plenty of it," can be given to such a case with safety. Let us have a reason for what we do. Let us feed our patient according to well known physiological laws, and with a scientific and accurate knowledge of what and how much he needs. It does not make one particle of difference whether the bacilli are found in the sputum or not. Whether the case is tubercular, hereditary, a result of the grippe, or what is the cause, the fact is that he responds to treatment just as quickly in the one case as in the other. Pay no attention to his plea that he "cannot eat meat." Put him at once upon a diet of broiled beef pulp and hot water, exclude all other foods and drinks, and wait for your results. It will not be long before the stomach accepts the terms offered, and goes to work in earnest; the appetite returns, and then the trouble is to keep the patient from eating too much.

Quantity of Food.—The appetite becomes ravenous, and the greatest care must be exercised to prevent the patient from eating more than can be assimilated. No good and much harm comes from over-eating. The appetite is no guide to quantity or kind of food. They want everything and will eat everything if you let them, but the oxidizing capacity of the body is limited. In the healthy adult it is estimated to be seven hundred and fifty grammes in a day, but this amount is largely diminished by the enfeebled condition of the consumptive invalid. If more than the required amount is taken there is trouble at once. Undigested food remains in the intestines to decompose and ferment, causing diarrhœa and other digestive disturbances, while nature attempts to eliminate some of the excess, or what has been absorbed

through the lungs, causing irritation there; more or less soreness is felt in the diseased area, the cough becomes worse, and the expectoration is more abundant and contains more pus. If this excessive feeding is allowed to continue, the kidneys are overtaxed, the urine becomes high in color and specific gravity, and is loaded with urates and uric acid, and finally albumin appears and grave symptoms of renal disease. The patient makes no progress under such conditions. When he has reached the point where other foods are allowed, still the greatest care must be used as to quantity.

The appetite for the C H O foods is great, and more will be taken than can be used. The oxidizing capacity of a healthy man being seven hundred and fifty grammes, about one hundred and thirty grammes of this should be nitrogenous food. The proportion of the latter must be far greater in the diet of consumptives, in order that there be a surplus, after supplying the waste, with which to build up the diseased tissues. If more than the required amount of the C H O foods is taken, the oxygen, uniting most readily with this class, oxidizes all of it first, till the supply of oxygen is exhausted and there is not enough left to carry the nitrogenous food through to complete oxidation, and, as a result, the body is deprived of just that kind of food it so greatly needs, while it has an excess of that for which it has little need, and which cannot contribute to the rebuilding of diseased tissues. The partly oxidized products in the form of uric acid, etc., remain to irritate the lungs and kidneys and to disturb the appetite and digestion.

The exclusive beef diet is to be kept up till the urine is clear and free and the appetite good, when a gradual enlargement of the diet along the line of whole meats, eggs, and bread, may be carefully entered upon. Fats and starches should be used carefully at first, till they are readily digested without acid fermentation. The cereals may be used when well cooked, but vegetables are best avoided. All desserts, sweets, made dishes, and fried foods should be avoided. Meats are best used freshly broiled or roasted.

The Excretions.—It will be seen from the foregoing how very important it is to watch the excretions during this process of feeding. The urine must be seen daily and its condition carefully noted. The stools should be examined microscopically for undigested food, the action of the liver and bowels stimulated by the proper laxatives, all the eliminations carefully attended to, and all errors of diet carefully guarded against. A regular and systematic washing out of the stomach is a valuable aid. It can be done either by drinking hot water and allowing it to pass down the alimentary canal, or by lavage with the stomach-tube. The former is to be preferred in most cases as it has the advantage of acting upon the liver and kidneys, and also of increasing the volume and fluidity of the blood, and thereby largely facilitating the elimination of the soluble effete matters. Lavage is more local in its effects. Either will improve the appetite and digestion.

Hygiene.—Another matter that is too commonly neglected is the care of the skin. Let us not forget that the skin is not a garment but an organ with important and vital functions to perform. .

The skin of a consumptive is always dry and indolent and unhealthy. Its circulation is poor and does not respond to the stimulus of cold, and the patient suffers from the lack of the protection which it should give. He shivers at every draught and "cannot bear the cold." The skin should be roused to do its work of elimination and of protecting the organs within. Daily sponge-baths, followed by vigorous rubbing of the whole surface will, in a short time, restore the normal tone of the capillary circulation, and the patient experiences a degree of comfort and safety perhaps never before known. He no longer shrinks from every draught, but has confidence in his ability to resist the cold. His skin reacts to every stimulating draught, and the blood, now abundant and rich, flows quickly to the surface, preventing all congestion of the internal organs, and changing what would have been a chilly sensation into a warm and comfortable glow. He no longer "catches cold" as he did, and is not as prone to the grippe, and if he does get it it goes lightly with him.

A healthy skin is of the greatest importance to the invalid. A weekly or semiweekly "tub," followed by oiling the whole body, contributes much to this end.

Exercise.—Too much care cannot be used in the matter of exercise in consumption. It must be carefully administered as the strength improves. Physical rest is the watchword during the active stage. A common error is to do too much under the impression that the more exercise and the deeper the respiration the more benefit. Bear in mind what changes occur must be physiological, and therefore slow. It is a mistake to push matters in this respect. Too much exercise induces overactivity of the lung, and is often the cause of active trouble. It should be taken cautiously, always within the limit of fatigue, and never just before or just after a meal. Pulmonary gymnastics are out of the question in this altitude. Sufficient activity and expansion of the lung is effected by the rarity of the air, and to exercise is to increase this activity to an extent that may be hurtful. Pulmonary exercise and physical exercise is what is wanted.

I feel sure that if some of the points briefly touched upon are more carefully observed, seventy-five per cent. of those who die here will be saved or largely benefited and restored to a much better condition of health.

Progress of Medical Science.

The Toxic Effects of Gallic Acid.—In a recent issue of the *New Zealand Medical Journal*, Dr. Thomas W. Bell contributes an interesting clinical note as to the possible poisonous effects of this remedy, which is regarded as harmless in anything like moderate quantities. A man, aged thirty-two, with internal hæmorrhoids, had a venous oozing with each passage of the bowels; various applications, including iron and cold water, had been used without any permanent benefit. One morning, just after an evacuation, he applied to the bleeding pile some ung. gallæ cum opio (B. P.). The piles were not painful and on their being replaced all discomfort ceased. After a little while he had for the first time in his life a slight attack of hay asthma, which was referred to the probable inhalation of some irritant dust. Three or four days later, after a second use of the ointment he had a similar asthmatic attack, followed by an urticaria lasting three or four hours, but no relation of cause and effect was thought to exist between the remedy and the subsequent outbreak. As the hemorrhage still persisted after each motion, Dr. Bell ordered a three-grain tannin suppository a short time before and after each movement of the bowels. The sequel is stated by Dr. Bell as follows: "In the afternoon, feeling quite well, he inserted a suppository. In about four minutes the symptoms of the asthma began to show. I watched the case throughout. First, there was pain and a tight feeling under the sternum, and a trouble in breathing; the breathing got quicker and labored, accompanied with wheezing and an occasional cough—until, in about half an hour from the time when the suppository was introduced, all he could do was to lie on the bed gasping and straining for breath, face flushed, hot, and perspiring, râles and rhonchi all over chest, and pain on coughing. With each cough a little pellet of mucus was expelled. This condition lasted for another half-hour, and then the pain and rapidity of breathing began to subside, but then the attack of urticaria commenced. Starting about the head and neck, it extended all over the body, and became especially marked about the feet. The irritation and itching was intense. Some of the wheals were from two to three inches in diameter. At the end of about four hours the

cough had stopped, the breathing had returned to normal, but the irritation of the skin continued in a less degree till next morning. The patient has never had any asthma, or anything approaching it, before or since, nor have any of his relatives ever had anything of the kind. Nor has he ever had urticaria or any skin eruption whatever." The physician was at a loss to account for these phenomena except as the effects of the gallic acid. No such result followed the use of various other remedies. None of the standard text-books attribute toxic qualities to gallic acid, either in the line of vaso-motor disturbance or that of skin eruption. Some peculiar idiosyncrasy seems to have existed in this patient.

Formation of a New Sphincter after Extirpation of the Rectum.—Dr. Willems has described a plan of preventing the fecal incontinence which so frequently occurs after removal of a portion of the rectum for malignant disease. The good results of simple separation of the fibres of the rectus muscle in gastrostomy have led him to believe that a similar advantage might be attained by fixing the cut edges of the remaining portion of rectum to a slit made in the gluteous maximus by forcible separation of its muscular fibres. The following are the steps of this procedure, which has hitherto been practised only on the cadaver: After removal of the lower part of the rectum, together with the sphincter, by the perineal operation, the body, if it has hitherto rested on one side, is now placed in the lithotomy position. If the rectum has not been divided very far above the anus, and its remaining portion can be readily drawn downward, a skin incision about two inches in length is made over the ischial tuberosity in an oblique direction upward and outward, so as to run parallel to the fibres of the gluteus muscle. A slit is next formed in this muscle about a finger's-breadth above its lower margin, by separating its bundles by means of a director or closed dissecting forceps. The extremity of the remaining portion of gut is finally drawn through this opening and stitched to the edges of the wound in the skin. When a considerable portion of the rectum has been removed and it is found impossible to drag down the gut margin as far as the ischial tuberosity, the author would endeavor to insert this end of the intestine at a higher part of the gluteus muscle and between the muscular bundles which arise from the margin of the sacrum. In such case the incision, which is made through skin and fasciæ, should be carried obliquely downward and outward from the right margin of the sacrum. The exposed muscular bundles having been separated, and also, if it be necessary, the sacro-sciatic ligaments divided, the end of the shortened gut should then, as in the former instance, be drawn through the slit and tied by sutures to the external wound.—*Centralblatt für Chirurgie.*

The Curative and Preventive Action of Mercury and Iodide of Potassium.—Dr. Mauriac holds that the two drugs most powerful in the treatment of syphilis do not realize the conditions essential to entitle them to be named as specifics, though they are incontestably superior to all other remedies which have been employed against syphilis. Their curative action is often wonderful, and can usually be implicitly relied upon when the drugs are given in accordance with the recognized clinical manifestations of the disease. In their preventive action, however, they are less satisfactory. This action is feeble, superficial, and transitory, since the outbreaks of the disease seem to be prevented not at all by the prophylactic treatment. There is only one condition under which this preventive action has proven satisfactory—that is, when administration of the specifics prevents hereditary transmission of the disease from the husband or wife free from apparent manifestations. Daily experience demonstrates that mercury neutralizes the latent infection of the spermatozoa of the sperm, the ovule, and the blood which occasions hereditary syphilis. This, again, however, seems to be transitory, since, after treatment and apparent cure, hereditary transmission may appear latent, and the parents themselves may be attacked by recurrences. It cannot be doubted that there is a tendency toward spontaneous cure in syphilis. Since well-directed treatment cannot injure the system, since it powerfully aids this tendency to spontaneous cure, the disease should never be abandoned to its spontaneous evolution. Whatever be the degree, form, tendency, or age of syphilis, it should always receive specific treatment. This is especially so when the disease is in its active state; medication should be directed not only against manifestations of the disease, but against the diathesis. Under these circumstances (the absence of symptoms) medication must be conducted somewhat by guesswork. Admitting that the syphilitic diathesis may be present, and admitting the value of the administration of specifics against this diathesis, the logical deduction would be to administer specifics during the entire period of life after syphilis is once acquired. This, however, is an unnecessary extreme, abandoned by its one-time most enthusiastic advocates. Mauriac believes that the best preventive results from the specifics are to be obtained by pushing their curative action as far as possible each time manifestations appear. The indications under these circumstances are clear and correct, and the dosing should always be full. In the intervals, when no external signs of syphilis are to be found, the mercury can be suspended until new developments require its administration. Mauriac believes that during the periods of latency the administration of a specific is without good effect, excepting as a means of preventing hereditary syphilis. Here mercury is incontestably the strongest guarantee against the chance of transmission of the disease.—*Therapeutic Gazette.*

Hepatic Venous Souffle.—Dr. Martini describes three cases of atrophic cirrhosis of the liver, accompanied by marked enlargement of the spleen, in each of which a continuous souffle, increasing during inspiration, could be heard in the sixth intercostal space about the right anterior axillary line (*The British Medical Journal*). In one case the souffle diminished after the patient had had hæmatemesis. Two of the cases ended fatally, but nothing was found which would obviously account for the peculiar souffle heard during life. The author is of opinion that this was due to a displacement of the ascending vena cava in consequence of the liver being pressed against it by the hypertrophied spleen and the ascitic fluid. The displaced cava would under such circumstances tend to become squeezed against the edge of the phrenic orifice of the diaphragm, below which it was, in fact, observed to have become widened. Under such circumstances the occurrence of a murmur might probably be due to the formation of a *veine fluide* at the site of the obstruction.

The Nerve Lesions of Leprosy.—Drs. Hallopeau and Jeanselme have published some observations on the multiple lesions affecting the peripheral nerves in leprosy. These lesions give rise to various forms of paralysis, anæsthesiæ, and to some amyotrophic conditions, which are especially remarkable both as regards their distribution and general character. It was chiefly in the limbs that these symptoms attained their maximum intensity; the extensors of the feet were especially affected and wasted rapidly. As regards the face, complete paralysis of the right facial nerve occurred within a few days, all the muscles supplied by it being affected; the right orbicularis muscle was implicated on each side, so that the eye could not be properly closed. Sensibility was abolished in the limbs in the regions around the elbows and knees, and it was perverted in the arms and thighs; thus the contact of a cold body produced the sensation of a hot one being applied. It was the same over the forehead. The nerves which supplied parts which had wasted had considerably increased in size.—*L'Union Médicale.*

It is Brutal to Relieve distress and then take a dollar—it ought to be charged, or be $10.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, November 18, 1893.

ARE AMERICAN WOMEN DETERIORATING?

IN the *North American Review*, Dr. Cyrus Edson, of this city, has stated that American women are deteriorating. They do not, he thinks, endure childbearing. Young women who are apparently strong, healthy, and active, marry, and have two or three or more children; in a few years their color is gone, they look old, they are nervous, fretful, easily fatigued, and have changed their freshness and youth for a premature age. They wander about in a gynecological Odyssey, seeking relief through operations which restore a tear in the perineum or cervix, or are curetted and electrified for a sub-involution, but, strangely enough, they do not get well.

Some such story as this is familiar to many of us; the question is, Does it represent a condition of affairs which is general? Two Chicago physicians have replied indignantly to the contrary. They have collected the histories of all the young families of their acquaintance and assert that in the vast majority the women are sound and healthy.

The question, however, is not to be settled so easily. We do not know how healthy the childbearing women of a generation or more ago were. Miss Catherine Beecher, writing in 1850, said they were a wretchedly feeble and valetudinarian class. As for to-day, only a very large number of observations can furnish a true answer to the inquiry. The statistics of the last census show a decided decrease in the birth-rate among Americans, and this is a rather serious indication of degeneracy. There is also a steadily increasing urban and decreasing rural population. This is not a healthful change for childbearing women. So that altogether it does not seem to us that the Chicago physicians have quite established their assertion that marriage nowadays makes more than it mars the health of American women. The problem is one of extreme importance, for upon it depends the future of our race. In this particular city it has been noted that the girls are larger and stronger than they used to be. In London the same is said to be true, but it is added that the men are not so vigorous. An observant Englishwoman in a recent interview states that American women are not so strong as the English, and she attributes this to the fact that mothers put their babies in boots (high shoes) instead of slippers with straps. The boots develop ankles that do not enjoy walking. This simple explanation of our physical inferiority is almost too good to be true.

ENDERMATIC USE OF GUAIACOL.

THE introduction of this remedy into therapeutics seems likely to be a great addition in several directions. As the essential element of creosote it has served well in tubercular affections, and is perhaps the most vaunted of all internal remedies for that class of maladies. Recently it has come to be used locally, and several of the recent French journals have contained quite remarkable statements as to its power when used in this manner, to reduce temperature.

In *L'Union Médicale* for July 11, 1893, are given the results of Robillard's experiments upon tubercular patients with fever. The amount of guaiacol used for each application was from one half to two grammes. Various bodily sites were made use of, varying in area from one to five decimetres square. It was found that with this dosage the temperature fell rapidly, in every case, from one to five degrees and remained low for several hours. The rapidity of action was greater than that of the quinine salts. It did not seem to make much difference over what area the application was made, arms, legs, chest, and back gave similar results. As might be expected, such a powerful effect has not been without its drawbacks. The patients have complained of a profuse sweating and a pronounced guaiacol taste. The urine has been increased in amount, but none of the remedy has been found therein. The foregoing facts prove beyond a doubt the existence of cutaneous absorption. Control experiments with harmless agents gave a negative result.

In *La Loire Médicale* of August 15th of the present year, we find still further allusions to this antithermic power of guaiacol. In an able article by Guinard, he gives credit to Sciolla as the originator of the endermatic use of the remedy. This latter experimenter placed varying quantities of the remedy upon the skin, and found rapid antipyretic changes to follow. This was true not alone in phthisical cases, but in pyrexias from all causes. Guinard alludes to the reports of Bard, Federici, and others, and states his surprise that, in view of the great resistance offered by the skin to the penetration of liquid or solid substances even of a fatty nature, an exception seemed to obtain in the case of guaiacol. He thought at first that the remedy must really have entered by the breath, in view of the rapidity with which its antithermic action was manifested. He assured himself of the truth of this fact by bathing with guaiacol the skin of a dog who, by means of a tracheal cannula *in situ* and connected with a long tube, breathed air which came from without the laboratory in which the experiment was made. In this case no trace of the remedy was found in the urine after two hours and three-quarters, during which time the temperature fell only one to two degrees. He argues therefore, that if none was found in the renal product none could have been absorbed through the skin. A control experiment had previously shown that the remedy, if inhaled, could penetrate through the respiratory channels into the system sufficiently, in the course of three hours, not to lower the temperature, but to appear slightly in the urine. While the results of these experiments were somewhat conflicting, the fact of the marked fall of temperature remained unexplained. Guinard was therefore led to search further for the cause of this very pronounced effect.

He advances the proposition that the effects of guaiacol upon the thermogenesis are probably the result of a selective action of this substance upon the peripheral nerve-endings. He found that two rabbits, one bathed with creosote and the other with a liquid preparation of mustard, showed practically the same fall of temperature under the same conditions of experimentation. A control experiment was made by bathing the hind limbs of two rabbits with guaiacol. In one the sciatic nerve had been cut four days before. Here the application caused no fall in temperature, while in the rabbit with nerve intact the same fall was observed as before. To establish the logic of the foregoing argument it was necessary to prove that guaiacol was irritant. Lepine had noticed that its application always caused considerable redness of the epidermis, but a purer product did not produce this redness. Guinard using pure guaiacol, generally found signs of local modification. In company with several other observers, he noticed that the temperature depression was greater if the region acted upon was covered with some light gauze like protective.

In this country, a recent brief note by Dr. J. Solis-Cohen (*Philadelphia Medical News*, September 30th) is the only mention of the method which has come to our notice. He employed it in two cases of phthisis. In one, a woman with a temperature of 102.4° F., thirty minims well rubbed into the skin over the pulmonary cavities, at 3 P.M., gave the following results: At 3.33, 99.3° F.; at 5 P.M., 97.4° F., when the patient was sweating considerably. The pulse was good and the skin warm. At 6.15 P.M., the patient was chilly and finger tips blue; at 6.35 P.M., temperature, 97.4° F., gradually rising to a little above normal. In this case it did not reach 102° again for several days. Similar trials gave like results both upon this and upon another patient.

From the foregoing observations it is evident that the febricide properties of guaiacol are more powerful than has generally been thought to be the case. The figures given in the various experiments suggest their own caution. The endermatic method is worth further trial, but the latter must be very cautiously made, and great care taken to see that collapse or other untoward symptoms do not follow.

A FRENCHMAN ON AMERICAN PROSTITUTION.

No Frenchman travels in America without making a more or less attentive study of the question of prostitution. The erotic feeling which dominates the life and literature and art of Paris makes the Parisian traveller feel that he must show some attention to the shady side of social life wherever he goes. So M. Marcel Baudouin, of Paris, after having shown to his countrymen that there was nothing of much interest in Chicago or the World's Fair, and after paying homage to the California Athletic Club, writes to *Le Progrès Médical* of "American Prostitution." He goes over the same old tales of the shameless openness of prostitution in our cities, of the lack of licensing and supervision, and ends with a very hard crack at New York, which he considers as "assuredly the most debauched city of the two Americas!" Such a statement will hurt the feelings of Chicago more than it will those of New York, for, as we understand the situation, Chicago's greatest pride, after the World's Fair, was in its immeasurable and unrivalled sinfulness. M. Baudouin adds the usual compliment of hypocrisy to our debauchery, and expresses in a general way his lament at the inferior condition of our public morals.

All this comes from a country in whose history is embalmed the infinite public rottenness of the Panama Canal. We are sorry Mr. Baudouin did not stop in New York long enough to see the work of our hospitals and colleges, rather than spending his time in the night displays of the Tenderloin district.

A HAY-FEVER CURE.

A TOUCH of hay fever produces feelings of human kinship to an extent not seen in other complaints. This we infer from the fact that the hay-fever patients of this country have formed an association, now twenty years old, for mutual condolence and help. We do not know of any other class of patients who are thus banded together in misery, though it might not be altogether useless if other similar organizations were established. The United States Hay-Fever Association publishes an annual report and offers prizes for the best essay on the subject of their pet malady. At the nineteenth annual meeting the prize was awarded to Dr. S. S. Bishop, of Chicago, and a copy of his paper is before us.

Dr. Bishop proposes a new theory and new treatment for hay fever. Adopting the suggestions and facts furnished by Dr. Alexander Haig, he asserts that the disease is of uric-acid origin, and that the paroxysms are brought on by the irritation of this acid, which gets into the blood in excess and causes the nerve-storms of sneezing, coughing, etc. The cure for an attack is to take ten to thirty drops of dilute sulphuric acid two or three times a day. The first dose should be taken early in the morning and should be largely diluted with water. In the intervals, or, more particularly, about forty days before an attack is expected, salicylate of soda and phosphate of sodium should be taken. A diet of milk, fruits, vegetables, butter, etc., should also be adopted.

Dr. Bishop does not say that uric acid is the only cause of hay fever, or that his treatment should exclude attention to nasal and other irritations, but by following it one causative factor that is often prominent, if not essential, is excluded.

Perineal Lithotomy in early childhood represents a safe operation and gives excellent results. A relatively enormous percentage of deaths in old age can be explained by the co-existence of grave complications about viscera (especially kidneys). Supra-pubic lithotomy does not offer any important advantages over the perineal operation. The mortality remains yet very high, even in children. Still, speaking generally, in the presence of stones measuring above two centimetres in diameter, the high section should be preferred, but in cases of smaller calculi perineal lithotomy should be performed. —LINDENBAUM.

Gonorrhœal Inflammation about Neck of Bladder.—Hourly doses of salicylate of soda up to ten grammes daily, when acute.—MEVNIER.

News of the Week.

A Hospital Boycotted.—The Charité Hospital of Berlin has been "boycotted" by the Social Democrats. An order has been issued by the party forbidding its members to go to the Charité, the reason alleged being that the syphilitic patients are treated with indignity.

A "Church" Saloon.—A saloon has been opened in this city under ecclesiastical auspices. That is to say, the proprietor has given a clergyman his bond to sell only pure whiskey and good beer, and not to sell to women, or minors, or drunken people.

Robbing Doctors' Offices.—Two men were recently caught who have been making a specialty of robbing doctors' offices. This is the first time we have ever heard of the New York police catching this class of sneak-thieves, and we are pleased to believe that the constabulary are waking up. If the New York police were a little more alive, doctors wouldn't have to put combination locks on their front doors, and chain their overcoats to the hat stand.

Cholera Therapeutics.—An enormous amount of rubbish seems to have been written regarding the treatment of cholera, since the epidemic struck Europe. Many of these ingenious measures have been tried in St. Petersburg during the past season. A correspondent of the *British Medical Journal* says: "The use of Cantani's hypodermic injections in the treatment of cholera has been now abandoned in almost all the St. Petersburg hospitals. They were found to be practically useless. In the Obuchovski Hospital intra-venous injections of saline solution are now being tried, but the benefit resulting from them appears to be as fleeting as it is, for the time, remarkable. All the physicians I have conversed with on this subject are agreed that heat, both external and internal, is the sheet anchor in the treatment of cholera. Very hot baths (both air and water baths) and hot rectal injections are of undoubted value—a statement that cannot be made unreservedly of any other remedial measure or drug, with the exception perhaps of stimulants, nervine and cardiac. Internal antiseptics of all sorts have been tried and found wanting by most observers, though at the 'Alexander Hospital, in memory of the Emancipation of the Serfs,' they are thought to be of some use."

India proposes to have a medical congress.

Died in the Discharge of Duty.—Three deaths have lately occurred among the younger members of the profession of Paris, in the performance of their medical duties, two from diphtheria and one from typhoid fever.

A Curious Omission.—Some surprise is manifested in the medical world that measles, whooping-cough, and erysipelas should be excluded from the list of infectious diseases drawn up by the Academy of Medicine, requiring notification and disinfection. These half-measures are condemned by the medical press, which considers that all contagious diseases should be declared, and this should be compulsory.

The Ohio State Asylum for Epilepsy.—Governor McKinley has declared open the new retreat for epileptics at Gallipolis. The trustees are ready to receive two hundred and fifty male patients, but they are not fully provided with the proper information to enable them to classify the applicants for admission. Dr. H. C. Rutter, who is the medical officer, may be addressed at the asylum at Gallipolis. The blank forms of application are in the custody of the probate court of each county, and those who seek the benefits of the new institution are desired to call upon the probate judge and fill out the regularly prepared papers.

Recovery of Damages for Miscarriage.—The Superior Court of New York City has ruled that when a married woman is so injured through the negligence of another person as to miscarry, her husband can recover damages for the loss of the child. In the case on trial the damage was assessed by the jury at $2,250.

Consumption Officially Declared a Communicable Disease in Michigan.—At its meeting of September 30th, the Michigan State Board of Health unanimously decided that consumption is a dangerous, communicable disease, and must be reported by physicians and householders to the several health boards.

A Medal Awarded to the Boston City Hospital.—A medal has been awarded to the Boston City Hospital for the completeness and excellence of its exhibit at the World's Fair.

The Death-rate in New York City last week was the lowest ever recorded, namely, 17.46 per 1,000.

Dispensary Abuses.—In perusing the discussion on the dispensary system in another column, it is impossible to resist the conviction that most of the dispensaries are badly managed, that there are too many of them for the real needs of the poor, and that the gratuitous services of the physicians are not properly appreciated. But is not this the old story? We are glad to see, however, that a good move has been made to have physicians members of the board of management.

Intestinal Obstruction in Children.—The announcement of this subject for discussion at a recent meeting of the Section on Pediatrics of the Academy of Medicine, drew one of the largest medical audiences which have been seen in the city during the season. The surgeons who discussed treatment of intussusception (the most common form of obstruction in children) favored early laparotomy, believing that the statistics would show a much larger percentage of recoveries if the surgeon were called and operated early. They admitted, however, the propriety of first trying pressure by water or gas during the first twenty-four hours. After that time gangrene was liable to exist and pressure might cause perforation. The general practitioners, on the other hand, seemed to have more confidence in treatment by pressure, and all who spoke gave preference to water over gas. The Davidson syringe was condemned. Use the siphon method, gradually elevating the reservoir above the patient, but not passing beyond a height of fifteen feet, which would cause a pressure on the gut of about six pounds to the square inch, the limit of safety in a child. To prevent water from escaping around the tube introduced into the rectum, use roller bandage.

Suggestions for the Improvement of the Naval Medical Service.—Surgeon-General Tryon makes the following important suggestions regarding the naval medical service. He first proposes to change the titles of the officers of the corps. The chief of the bureau he would

call Medical Director-General, thus leaving Surgeon-General exclusively an army title; the Medical Inspector would hereafter have the name of Fleet Surgeon; the Passed Assistant Surgeon—an awkward designation—would be Surgeon, while the present Surgeons would become Staff Surgeons; finally, the title of Assistant Surgeon he would make Surgeon Junior Grade, just as in the line there are Lieutenants and Lieutenants Junior Grade. A second point noted is that Passed Assistant Surgeons, after remaining in that grade for fifteen years, are promoted without either physical or professional examination to the grade of Surgeon, where they remain about as long before being examined to be made Medical Inspectors. This makes a consecutive service of perhaps twenty-five or thirty years without having their qualifications tested by examination since promotion from their status as Assistant Surgeons. The remedy is to commission Passed Assistant Surgeons on reaching their grade, and then to promote them to the grade above only after a regular physical and professional examination. Legislation for that purpose could easily be supplied by Congress. A third point suggested by the Surgeon-General is that, since medical officers must lose professionally during each cruise of three years at sea, a partial offset could be had by sending some of them as attachés to the legations of London, Paris, and Berlin, the chief medical centres of Europe. Besides getting opportunities for study there, they might make valuable reports upon all matters connected with public health, and so be of much service while absent from routine duties. Finally, the Surgeon-General shows the need of repairing and enlarging the naval hospital at Brooklyn. It is overcrowded; it furnishes less than one-third as much air-space per man in its wards as well-equipped modern hospitals give; it has bad floors, ceilings, plumbing, and defective ventilation and heating; in short, it should be renovated as well as extended throughout.

A New East Side Hospital was opened recently at East Eighty-sixth Street. It is a Maternity Hospital under Catholic auspices, and will have accommodation for one hundred and thirty patients. The hospital will cost about $110,000. Dr. T. J. McGillicuddy is the attending physician.

Caffein Sulphate is recommended by Drs. Heinz and Liebreich as a diuretic. It acts somewhat like diuretin, but the dose is smaller.

A Memorial is to be erected to the late Surgeon-Major Park.

Professor Virchow celebrated his fiftieth doctorate jubilee on October 21st. The *Berlin. klinische Wochenschrift* devotes a special number to the event. Virchow was so recently celebrated on the occasion of his visit to London, that a return to the subject is just now hardly necessary. Professor Virchow deserves all his honors, and may he live long enough to enjoy many more.

Medical Fees in Russia.—The Czar of Russia recently issued a ukase on medical fees which divides the population into three separate classes, the first one composed of the nobles, the capitalists, the landowners, the manufacturers, the bankers, the principal merchants, and members of the first six classes of the civil, military, and naval service. The second class comprises lawyers, parsons, and professional men of one kind and another, as well as government employees of the seventh and eighth grades; while class number three is of the balance of the population. For patients of the first class the fee is limited under severe penalties to $2.75 for each consultation; for those of the second class to $1.65; while the cost of medical advice to the masses is limited to 19 cents. If the fee were proportioned to incomes, the first class would pay $27; the second, $16; while the 19 cent fee would remain.—*Medical Standard.*

A New Form of Ambulance.—Among the novelties in the way of ambulances, is an ambulance car that is to be introduced upon the electric street-car system of St. Louis. It seems that the health commissioner, Dr. George Homan, has devised a plan that the car company are giving him cordial support to perfect. It consists of an emergency hospital on wheels, with the springs so constructed as to prevent severe jars to the occupants of the car.

Washington, which has already four medical colleges, is now favored with a fifth, viz., the National Homœopathic Medical College.

Professor Potain has been elected successor to the late Professor Charcot, in the Académie des Sciences.

Emergency Hospital at the World's Fair.—There were treated at the World's Fair Emergency Hospital, 18,500 cases, and there were twenty-three deaths at the institution.

University of Georgia.—The Medical Department of the University of Georgia is against the abolishment of the Board of Medical Examiners by the State Legislature, and makes an earnest appeal that it be re established. The professors of the Medical College adopted the following resolutions:

Whereas, It is an indisputable fact that since the Board of Medical Examiners of Georgia was abolished by act of the Legislature, Georgia has been a veritable paradise for quacks who have been driven out of other States;

Resolved, That the Faculty of the Medical Department of the University of Georgia heartily indorses the principal features of the bill as printed in the *Atlanta Medical and Surgical Journal*, December, 1893, pages 612, 613, and 614, captioned, "A Bill to be Entitled an Act to Establish a Board of Medical Examiners for the State of Georgia, and to Protect the People from Illegal and Unqualified Practitioners of Medicine," which bill was passed by the Senate of Georgia at its last session.

Resolved, That a committee of three members of this Faculty be appointed and charged with the duty of appearing before the Legislature of Georgia, and using all honorable means to secure the enactment of said bill.

Resolved, That this Faculty, through the said committee, requests the Senator from this Senatorial district, and the Representatives of the Lower House from this county, to exert themselves to secure the passage of said bill.

Resolved, That this College points with pride to the fact that it was the first medical school in America to insist upon the necessity of higher medical education in the colleges of the United States. This fact is shown first, by the record that in 1825 the first board of State medical examiners was organized at the request of the board of trustees of this college; second, in the early history o-

this college the term was six months. In 1845 the faculty of this college attempted to have all medical colleges in America require of their students attendance on two full courses of six months each, as a requisite to graduation. This medical school only receded from its then advanced position, because forced to do so by refusal of all other colleges to join in the movement, no other college having expressed a willingness to join in the crusade against the disgraceful practice of yearly graduating large numbers of ignorant and unqualified medical students.

Resolved, That it is, in the opinion of this faculty, a blot upon the escutcheon of the State, to permit Georgia to be without a board of medical examiners to protect her citizens against medical pretenders.

Professor Charcot's Successor at the Salpêtrière.—Insurmountable difficulties appear to have arisen in the choice of a physician deemed worthy to take the late Dr. Charcot's place at the famous institution which his neurological researches have made famous all over the world; a compromise has accordingly been arrived at in the nomination of Dr. Brissaud for the period of one year, at the end of which term it will be decided whether he is to continue to hold the office.

At the Meeting of the International Medical Congress which is to be held at Rome next April, it seems likely that a proposition will be made to hold the twelfth meeting of the Congress in the capital, or some considerable town, of Russia.

Suit for Malpractice.—Dr. Marcus E. Babcock, of Branchport, N. Y., is to be congratulated on winning the suit of malpractice brought against him in April, 1892, by John Bell, of Branchport. Bell, in June, 1891, severely injured his right hand, breaking and partly dislocating the second joint of the right little finger. He also claimed to have dislocated the third joint of the same finger. Dr. Babcock treated the hand seven weeks. In the fall of 1891, it appeared that the third or knuckle-joint of the same finger was so dislocated that it would not remain in place, and causing the finger to seriously interfere with the prosecution of his trade and producing great suffering. In April following, he brought an action in the Supreme Court against the doctor to recover $1,000 damages, claiming that the third joint was dislocated when the second was, and that the doctor failed to discover and properly reduce and treat the dislocation. The case was on the calendar and finally referred to Mr. William H. Nichols, of Bath, as referee. The action was stubbornly fought on both sides. On August 5th, the learned referee made his decision, exonerating and sustaining the doctor, and dismissing Bell's complaint with costs.

Dr. Charles Wesley Stanley, who died in this city on October 26th, was born in Conway, N. H., on May 28, 1828. He received his early education at the Oneida Institute, and was graduated in 1866 from the Medical Department of the University of New York. In 1870 he removed to Chicago, where for over twenty years he was actively engaged in the practice of his profession. Dr. Stanley was quiet and retiring in disposition, and a devoted student. As a physician he was capable and sympathetic, and by his kindly nature he endeared himself to all with whom he came in contact. He was married in 1869 to Miss Harriet Armstrong, who survives him.

Medical Society of the University of Maryland.—At a meeting held for the purpose, at the University of Maryland, Baltimore, the "Medical Society of the University of Maryland" was organized with the following officers: *President*, Dr. J. J. Chisolm; *Vice-President*, Dr. C. W. Mitchell; *Secretary*, Dr. W. B. Canfield; *Executive Committee*, Drs. J. E. Michael, W. B. Platt, and J. M. Hundley. The society will meet on the first Tuesday of each month, and will be composed of the faculty, the adjunct faculty, members of the teaching and hospital staffs, and graduates of the University.

Malaria Prevalent in Denver for the First Time.—County Physician Dunlin, of Denver, says there are several hundred cases of genuine malaria in Denver now, for the first time in the history of that city. The chills and fever are identical with the Illinois variety, but there is no shaking, it taking more the form of dumb ague.

Beri Beri in Philadelphia.—The steamship Lenark, Captain W. B. Cross, from Java, via Port Saïd, Algiers, and Gibraltar, arrived at Philadelphia November 3d, with her crew sick of beri beri. Quarantine physician Dr. Henry C. Boenning writes that, "there are eight cases of beri beri in our hospital and thirty-one suspects in the barracks, held for observation. The cases are well marked." Fifty Hindoos and several Arabs composed the crew. Mohammedans are mutton eaters. The cargo was sugar.

The State Medical Society of Maryland will hold its semi-annual meeting at Annapolis, Md., Tuesday and Wednesday, November 21st and 22d. There is a prospect of a full and interesting meeting.

Reviews and Notices of Books.

RINGWORM. Its Constitutional Nature and Cure. By J. COMPTON BURNETT, M.D. Philadelphia: Boericke & Tafel.

THAT ringworm is due to a specific fungus is one of the certainties of practical medicine. The author makes this statement, and then through one hundred and twenty pages tries to prove that it should be treated by internal remedies. Throughout there comes occasionally to the surface the underlying idea that there is close relationship between tuberculosis and ringworm. So far as the opinion is upheld that the parasite may only flourish on soil suitably prepared for it by preceding constitutional disease, we have no serious criticisms to oppose. We are far, however, from believing that the author has proven his case.

DECIPHERMENT OF BLURRED FINGER-PRINTS. By FRANCIS GALTON, F.R.S., etc. Pp. 18, with 16 plates. London and New York: Macmillan & Co. 1893.

THIS monograph is a supplementary chapter to the author's more elaborate work on "Finger prints." The whole matter is of medico-legal importance, with reference to the identification of criminals by comparison of registered prints made as described. The conventional objections to this method have always been, first, that the ordinary official would not take the prints with sufficient sharpness to have them of any use; and, secondly, that no jury would ever convict a man on finger-print evidence. The author has had the opportunity of comparing prints made by the same persons at intervals of fourteen years. From the evidence thus presented he endeavors to reply to the objections above stated. The well executed plates illustrate his text in a graphic manner. The work is of great interest.

Society Reports.

AMERICAN ORTHOPEDIC ASSOCIATION.

Seventh Annual Meeting, Held at St. Louis, September 19, 20, and 21, 1893.

President's Annual Address—The Embodiment of an Idea.—Dr. A. J. Steele, the President of the Association, said that each advance in orthopedics first existed only as an idea in the mind of man, to finally become embodied in a perfected operation or mechanical device. He dwelt particularly upon the importance of subjecting each new device or plan of treatment to a thorough and extended test before rushing into print, and pointed out the time lost to the surgeon and the harm done to the patient by the publication of an ill-digested idea and unproven plans of treatment. Each member was urged to contribute his share of inventions and experience, that the whole might be a credit to the specialty.

Some of the Uses of Continued Extension.—Dr. Henry G. Davis, of Everett, Mass., communicated a paper with the above title, which was read by the Secretary. The author reviewed his early work in the use of extension, and pointed out its usefulness in the treatment of all diseases of the joints; for the reduction of long-standing dislocations; for old cases of supposed anchylosis; for treatment of fractures of the neck of the femur; for elongating the true skin to supply the place of the cicatrix of a burn; for enlarging the cavity of the chest; for a trying fracture of the patella; for the reduction of spinal kyphosis of the neck accompanied by paralysis; and as a means for preventing shortenings in all chronic joint diseases.

Cases of Osteo-sarcoma Simulating Tubercular Hip Disease.—Dr. A. J. Jillette, of St. Paul, reported several cases, and pointed out the difficulty in differential diagnosis in this class and hip disease.

The Double-lever Stretching Apparatus for Club-foot.—Dr. T. Halstead Myers presented through the President a paper describing his apparatus. The apparatus is a modification of the Thomas osteoclast, the handles being so arranged as to hinge at the middle post, and the upright posts arranged to slide upon the handles and lock with a thumb screw so that a single handle can be used, somewhat after the manner of the Thomas club-foot wrench.

The Treatment of Lateral Curvature by Means of Pressure Correction and Gymnastics.—Dr. L. A. Weigel, of Rochester, read a paper with the above title, illustrated by a large number of lantern-slides. Dr. Weigel treats lateral curvature by means of a compression apparatus developed on the principle of that used by Drs. Bradford, of Boston, Hoffa, of Wurzburg, and Shede, of Hamburg, and supplements by a removable paper corset fastened with elastic lacings, and by exercise. Up to the present time Dr. Weigel has not treated these cases by the permanent plaster jacket applied to the patient while corrected by the pressure force, but he has demonstrated that even in very bad cases the bony deformity can not only be temporarily effaced by the pressure, but that in many cases the opposite deformity can be produced.

Correct Form and Expression, and Incidentally One Case of Lateral Curvature.—Dr. O. A. Wall, of St. Louis, by invitation, lectured upon the above subject, and illustrated his remarks by a large number of lantern-slides. He pointed out the facts that girls are constantly trained to stand with the weight resting upon one foot or the other, and constantly cautioned not to stand awkwardly erect. Standing with the weight resting upon one foot causes a temporary lateral deviation of the spine, and this was believed by the speaker in some cases to form the starting-point of a permanent lateral curvature.

The Mental Condition of the Patient as an Element in the Treatment of Joint Disease.—Dr. Ansel G. Cook, of Hartford, Conn., read a paper with the above title, and urged upon the Association the importance of a cheerful and happy frame of mind as an element in the cure of all chronic surgical affections. Special reference was made to the importance of an out-door life, and pleasant surroundings, and healthful occupation of the mind, and the author believed that carious bone would heal, and long-standing tubercular sinuses would close rapidly, when the patient was given his liberty, after the healing process had remained obstinately inactive for months during confinement in a hospital ward.

A Case of Fragilitis Ossium.—Dr. Wallace Blanchard, of Chicago, reported a case of a young woman, aged twenty-seven. At birth she was believed to be a healthy baby, but during the second month of life she suffered a fracture of the left femur, at or near the neck, and demonstrated the brittleness of her osseous system over twenty years with astonishing frequency. The case was first reported by Dr. Blanchard in 1875, at which time the following fractures had occurred: Right arm, 3; right forearm, 4; left forearm, 3; right thigh, 2; left thigh, 3; right leg, 14; left leg, 11; total, 40. There was also evidence at this time of there having been a transverse fracture of the sternum between the fourth and fifth ribs. The mother of this girl has become so skilled in the treatment of these fractures that the surgeon has not always been called to attend her, but in so far as can be learned there has occurred, up to the present time, over seventy-two accidents, including at least one hundred and sixteen fractures of the long bones. In these fractures there is but slight evidence of laceration and contusion, such as occur in fractures in a healthy subject, as well as the inflammation and congestion that usually accompany it; consequently this patient has suffered comparatively little pain. The process of union has been tedious in the extreme, soft union only being present on the removal of the dressings at the end of the seventh or eighth week, and two or three years being usually required to bring the union to any considerable firmness.

A New Traction Mechanism for Hip splints.—Dr. L. A. Weigel, of Rochester, N. Y., exhibited a hip-splint with a traction mechanism, which consisted of a coarse screw which telescoped into the shaft of the splint, this shaft being constructed of steel tubing. For the purpose of preventing the screw from rotating within this tubing a feather is braced in, which works in a groove cut in the screw. Traction is obtained by running the screw out by turning a milled nut. When a desired amount of traction is obtained this nut is firmly held in position by a lock-nut, which prevents all possibility of the screw going back from its position by concussion in walking, or other means.

The Question of Excision of the Hip-joint for Tubercular Disease, with Results of the Operation.—Dr. Harry M. Sherman, of San Francisco, read a paper with the above title, of which the following is a summary:

Not Submitted to Operation.

Perfect recoveries	7
Imperfect "	10
Dead	4
Passed from observation	40
Under treatment	21
	— 82

Submitted to Operation.

None in	1 case (error).
Slight in	14 "
Medium in	5 "
Bad in	5 "

Limp—Non-operative Cases:

Bad in every case.

Etiology of the Deformities of Knee-joint Disease.—Dr. A. M. Phelps, of New York, in place of his formal paper with the above title, made some remarks on the subject illustrated by blackboard drawings. The principle of his experiments is the same as that which he applied to the deformities of hip disease, published in these columns some time since. He showed that the extensor muscle group is stronger than the flexor muscle group, when the limb is straight at the knee, but in the case of tubercular disease in either the femur or tibia, the patient voluntarily flexes the leg on the thigh to some degree to relieve the pressure upon the tender spot. Now, when the leg becomes flexed, the extensors are placed at a disadvantage, and the flexors at an advantage, and they become the stronger of the two. This results in the flexion deformity which is always met with in cases of knee-joint disease, and the subluxation which is found present in very many.

The History of the Treatment of Tumor Albus of the Knee.—Dr. J. D. Griffith, of Kansas City, read an elaborate historical and statistical paper with the above title. He reviewed very completely the literature of the subject, and gave statistics of various plans of treatment, referring especially to excision of the joint, obtained from records of the Surgeon-General's office in Washington, statistics obtained from a large number of letters received from American surgeons, detailing the number of cases treated, the means of treatment employed, and the results. He went on to discuss the various medicinal and mechanical remedies employed, but offered no new suggestions for the treatment of the disease, except a further plea for the administration of guiacol.

The Present Form of the Thomas Knee-splint.—Dr. John Ridlon, of Chicago, exhibited two splints and a cutting appliance for the transformation of one splint into the other, and made some remarks on the subject. He said that the form of Thomas knee-splint ending in a patten at the bottom, which is in pretty general use, had not been used by Mr. Thomas for some time prior to his death. The speaker had not used it for some three years, because, in his opinion, it gave less effective immobilization than the caliper form of splint. In the splint with the patten ending, the foot and leg dangles and not only tends to move from front to back, and from side to side, but to also rotate. He urged the use of the bed form of splint, which extends far enough beyond the foot to prevent the patient from walking, terminating in a loop which can be utilized to fasten the straps from adhesive plaster in those cases where traction is demanded. Patients should be kept recumbent in this splint until all deformity has been corrected, and all pain is gone, and some considerable advance made toward convalescence, then with the cutting appliance the loop end of the splint is removed, and the cut ends bent toward each other to form the caliper splint, and inserted into a tube in the heel of the shoe. Care must be taken that the ends of the splint be bent at such a point that, when applied to the limb, the heel of the foot cannot reach the sole of the shoe, that all concussion may be saved from the joint in walking. The splint, fastened as it is to the shoe, effectually protects the joint from any rotation of the limb.

Exhibition of a New Knee-splint, its Action and Advantages.—Dr. A. E. Hoadley, of Chicago, presented a new splint, consisting of two perforated metal troughs, joined by one T-shaped and two straight slotted steel bands, which locked by a series of thumb-screws, and made it possible to place the metal troughs at any

desired angle or relation to each other, and securely fastened in such position.

A Simple and Effective Knee-splint.—Dr. Wallace Blanchard, of Chicago, exhibited a knee-splint constructed of two pieces of sole leather moulded upon a plaster cast of the limb to an accurate fit and laced in the front, the two being joined posteriorly by a strong bar of soft iron. To the top of the thigh-piece and the bottom of the leg-piece, both on the inner and outer sides of the limb, buckles are attached as a means for obtaining traction. The leather pieces are secured to the limb by lacing in front. The iron bar posteriorly can be bent to fit any angle of deformity, and straightened as the deformity is reduced during the subsidence of the inflammatory process.

Bone Operations for the Correction of Club-foot—Based on an Analysis of 341 Operations by 108 Operators.—Dr. H. Augustus Wilson, of Philadelphia, Pa., read a paper upon the above subject. The mortality was one and four-tenths per cent. Death was caused as follows: Three from septicæmia, 1 from diarrhœa, and 1 from septicæmia following amputation which was done for unavoidable hemorrhage after a bone operation. In addition, correspondence elicited two other causes not included in table—one where was suppuration with subsequent amputation and death, and another where amputation was required, and death. Gangrene occurred in 1 case; suppuration occurred 21 times, or six per cent. In 41 cases the age was not stated. The earliest age at which bone operation was performed was two months. Seven (two and one-half per cent.) were operated upon prior to the age of one year; 16 (five and one-third per cent.) prior to two years; 81 (twenty-seven per cent.) prior to six years; 165 (fifty-five per cent.) prior to ten years. Between the ages of six and eighteen 174 (fifty-eight per cent.) cases were operated upon. The oldest patient was forty-seven.

In 123 cases, or thirty-six per cent., the astragalus was the only bone removed; in 190 cases, or fifty-five per cent., the astragalus was removed together with other and surrounding bones. The greatest amount of bone removed was when, in addition to Phelps's operation, the astragalus, cuboid, third cuneiform, scaphoid, anterior of os calcis, and the malleolus were removed.

In one other case there was an osteoplastic resection after Vlarmiroff Mikulicz. Tarsectomy, without describing extent, was performed eighteen times. A wedge of tarsus was removed sixty-one times. In 20 cases Phelps's operation was done, in 13 of which more or less extensive bone removal took place.

With comparatively few exceptions braces were required after operation. On the whole, the study of these 341 cases would indicate that in a very large number better functional results, as well as a more natural-appearing foot, could have been obtained by recourse to soft structure section and properly constructed mechanical appliances.

Cases suitable for bone excision are becoming more and more rare as the importance of early treatment, persistently maintained, is becoming more thoroughly appreciated.

The Cause of Flat-foot.—Dr. Newton M. Schaefer, of New York, read a paper in which it was claimed that many cases of flat-foot were solely due to a shortening of the gastrocnemius muscle. The shortened muscle was pulled by the heel, and in so doing not only stretched the plantar tissues but actually tipped downward the tarsal joint. In such cases the remedy consisted in elongating the active muscle by a stretching apparatus.

Exhibition of a Paper Corset, also an Apparatus for Recording in Lateral Curvature.—Dr. L. A. Weigel, of Rochester, exhibited a spinal corset constructed of alternate layers of linen and the kind of matrix paper used in the stereotyping process. The construction of the jacket is much the same as Waltuch's wood corset, being made from a plaster cast. The corset is laced in front with elastic lacings.

The apparatus for recording the rotation in lateral curvature consisted of a board upon which are fastened two parallel rods, upon which slides a third rod set at right angles to the first two. At the end of this third rod is attached a small wheel playing around a peripheral axis instead of a central axis. Nearing the other end of the rod a pencil is attached which traces a line upon the paper placed upon the board as the wheel is made to follow the outline of a cross-section of the patient's thorax.

An aluminium corset hinged at the back was shown by Dr. Phelps.

Does Traction Distract in Hip Disease?—Dr. E. H. Bradford, of Boston, said that although there is a general opinion that some advantage can be expected from traction, and in many places traction is employed, yet many deny that any benefit is to be expected from it, and a few regard it as almost injurious. Pathological evidence is of the first importance in an inquiry of this sort, and the pathological finding is that in all mechanical inflammatory processes at the hip joint the head of the femur is displaced upward and backward toward the upper and posterior part of the acetabulum. This can be seen on examining every pathological specimen of hip disease. It is clear that if a force in hip disease can be applied counteracting the backward and upward pressure, it would be of therapeutic benefit, first, in relieving the amount of distraction of the bone from increase and pressure; and second, in checking the inevitable deformity following the cure of hip disease.

To overcome this upward and backward force there should be a force in the opposite direction sufficient to counteract the increased muscular spasm, and also to actually distract, that the inflamed bones may not be crowded together, and that the cicatrization of the granulations and diseased tissues may take place uninterrupted by the friction and pressure of contiguous portions of inflamed bone pressed together. An articular bone surface relieved from pressure heals readily, as is seen in cases of amputation of the hip where a carious acetabulum readily heals.

These above-mentioned facts would readily be accepted beyond dispute, but the bone of contention would be found furnished when the statement is made that in hip disease a diminution in inter-articular pressure can be practically brought about by mechanical means, and to an extent which is not only practicable but also beneficial. The questions as discussed were not complicated by consideration of the advantages of fixation in hip disease, but the inquiry was limited to the simple question—Does traction distract; and if so, under what circumstance can distraction take place?

The experiments and observations made by several observers on cadavers and on living persons, prove without the possibility of a doubt that traction properly applied can and does distract the diseased hip-joint in the inflammatory stage, provided traction is applied with the limb in a slightly flexed position.

It is also found that lateral traction aids in distraction, that lateral traction alone is not as effective as lateral traction and horizontal traction combined, that the check to traction are the muscles and the ligaments, particularly the ileo-femoral ligament, that in the stage of hip-disease where cicatrization has taken place traction does not distract.

The Manual Treatment of Bow-legs and Knock-knees.—Dr. Samuel Ketch, of New York, read a paper upon the above subject, showing the excellent results which might be expected from constant and faithful attention to these deformities by stretching alone. He advises against trusting this work to the mother, and urges for the child to be brought to the surgeon three times a day.

A Surgical Cot.—Dr. Weigel presented for Dr. John Schapp, of Brooklyn, N. Y., a cot developed from the familiar canvas-covered frame, with provision for supporting it at any convenient height or incline, and for the application of adjustable pressure to any part of the spine, traction to the spine or to a limb, and for suspend-

ing a limb. It is designed to maintain an uninterrupted recumbency so that the parts under treatment remain unchanged, or subject to only such change as the surgeon may determine. A hole, long and narrow, is provided for urination and defecation. This hole is closed by a flap secured by stout straps. Padded straps are sewed to the canvas to buckle around the shoulders. A pelvic belt, laced on and provided with two buckles, is used to strap the patient's pelvis to the cot, and also to make some counter-traction. Traction is applied to the head by means of a head-piece, the cord from which passes several times around a wooden drum to the weight. By means of a parasol and rubber-tired wheels it is converted into a perambulator.

Election of Officers. — The following officers were elected to serve for the ensuing year: *President*, Dr. A. M. Phelps, of New York; *First Vice President*, Dr. H. Augustus Wilson, of Philadelphia; *Second Vice-President*, Dr. Harry M. Sherman, of San Francisco; *Treasurer*, Dr. E. G. Brackett, of Boston; *Secretary*, Dr. John Ridlon, of 103 State Street, Chicago.

AMERICAN PUBLIC HEALTH ASSOCIATION IN CONJUNCTION WITH THE INTERNATIONAL CONGRESS OF PUBLIC HEALTH.

Twenty-first Annual Meeting, Held in Chicago, Ill., October 10, 11, 12, 13, and 14, 1893.

(Continued from p. 570.)

Second Day, Wednesday, October 11th—Evening Session.

Pathogenic Bacteria. — At this session Dr. George M. Sternberg, Surgeon-General of the United States Army, delivered a stereopticon lecture on "Pathogenic Bacteria." Slides of the typhoid bacillus, the bacillus of anthrax, of tuberculosis, of glanders, of tetanus, of influenza, of hog cholera, etc., were shown.

On motion of Dr. A. R. Reynolds, of Chicago, a vote of thanks was extended to Dr. Sternberg for his entertaining lecture.

Third Day, Thursday, October 12th—Morning Session.

Tuberculosis and the Food-supply.—The first paper read was by Dr. D. E. Salmon, Chief of the Bureau of Animal Industry, with the above title. The author assumed without argument, as already established by scientific investigation, that tuberculosis is a parasitic disease, that it is caused by the multiplication of a specific micro-organism in the tissues of the animal body, and by no other means. Of the two methods by which the disease is contracted with men, as well as with animals, it may be admitted that the most frequent, and therefore the most important, is the inhalation of the micro-organisms suspended in the inspired air. The speaker had no means of estimating the proportion of cases of tuberculosis which arise from infected food, but he was prepared to admit that tuberculosis of the abdominal organs and tubercular meningitis, particularly of children, were generally caused in this way. The author then considered infection through the milk-supply and infection through the meat-supply. Tuberculosis is one of the most common diseases of milch cows. It exists in many dairies, and may affect fifty, seventy-five, or one hundred per cent. of the animals in large herds. We do not know the average proportion of cows affected in this country, but in the dairies around our large cities from three to five per cent. have been affected when the diagnosis was made by the ordinary methods of examination. In the United States we have no statistics of the results of the tuberculin test, except with herds known to be tuberculous. Fortunately the milk from all tuberculous cows does not contain the bacilli. When there are tubercles in the udder, however, the milk may contain immense numbers of these germs, and this is particularly the case if the tubercular mass softens and its contents escape into the milk-ducts. The milk from cows so affected must be considered an extremely dangerous article of food.

The prevalence of tuberculosis in dairy cows can be lessened, and the danger from infected milk diminished, by a careful and periodical inspection of the herds from which the milk supply is obtained. This inspection must consist not only of a physical examination, but must also include the tuberculin test. There must in addition be some means provided for securing the destruction of animals found to be tuberculous.

Syphilitic Infection as a Vehicle of the Communication of Tuberculosis, by Dr. Manuel Carmona y Valle, of Mexico. The author of this paper cited the history of a case demonstrating the possible association of the syphilitic virus with the pathogenic agent of tuberculosis, and the possibility of transmission not only of the syphilis, but of the tuberculosis also. He had found in the ulcerations of the throat both characters.

The Influence of Habitations in the Propagation of Tuberculosis, by Dr. Manuel Gutierrez, of Mexico. Pulmonary tuberculosis is more frequently observed in the United States than in the republic of Mexico. The statistical records give a proportion of from one hundred and eighteen to one hundred and twenty per thousand in America, while in sunny Mexico it does not reach the number of sixty to every thousand. One of the causes which contribute to produce so notable a difference in the propagation of so dangerous a disease is the difference in the elevation in both countries, because we know that dry air is not a vehicle for the multiplication and generation of the bacillus of Koch, and the relative rarefaction of the air is in a direct ratio to the elevation. Mexico being two thousand two hundred and fifty-seven metres above the sea-level, it is consequently not difficult to explain its superiority in arresting the conditions favorable to the propagation of a disease which undermines so many constitutions.

The author's attention has been called to the fact that not only in the hotels and public establishments, but also in private dwellings in the United States, there are rooms constantly illuminated with artificial light and in which the light of the sun never penetrates. The individuals who work therein are deprived for many hours of the beneficial action on the economy that we know solar light exerts, and we know that this privation, and the special conditions that accompany it, can contribute to the development of tuberculosis by producing, 1, the anæmia and its consequent state of malnutrition, preparing the ground that serves for the cultivation of the germs of the disease; 2, increasing considerably the temperature of the place illuminated constitutes also a propitious cause of multiplication of the pathogenic principles involved and in the tuberculous process.

Prophylactic and Therapeutic Value of Food.—This paper was contributed by Mrs. Ellen H. Richards, of Boston. She said the prophylactic value of food is to keep the human body in a high condition of health. The main object to be gained is to establish a higher standard of health in the community, to make as widely known as possible the fact that most of the ill health now prevalent is needless; that a little self-denial, a little more attention to the rules of hygiene, a little more living in the open air, would cause a large number of the diseases now so common to disappear.

Hygiene of Hair-dressing and Barber Shops, by Dr. Angel Contreros, of Pueblo, Mexico. The disease which persons are most liable to contract in barber shops is scurf, and the author therefore touched on what appeared to him the most important points in the consideration of this matter. Scurf is understood to be a disease of the capillary system caused by the presence of vegetable parasites. The disease can be transmitted by some animals which already have it; but the contagion most commonly takes place from person to person and in families; in educational establishments and in barracks the disease

assumes an endemic character. Several times the centre of this propagation has been found in a hairdresser's or barber's shop, and has arisen from the use of instruments which have been badly cleansed. Barbers and hairdressers ought therefore to be very careful in cleansing the utensils which have served for one person before they are employed on another. All the utensils should be subject to the action of heat for a space of ten minutes, in a vessel or receptacle, at a temperature of 120° F., and the razors in an oil bath.

The Water-supply of Chicago, its Sources and Sanitary Aspects, by Dr. Arthur R. Reynolds, Commissioner of Health of Chicago, and Mr. Allen Hazen. The extensions of the various tunnels within the last two years have undoubtedly secured for the city a water less liable to sewerage pollution than was formerly obtained. The available analyses of the water are perhaps inadequate to measure accurately the improvement, but fortunately we can apply that most satisfactory of all water tests, the typhoid fever death-rate. The improvements in the water intakes have not all been made at a single date, but if we compare the two years ending September, 1892, and September 30, 1893, we find that during the earlier years the shore intakes at Lake View and Chicago Avenue were in common use, while the four-mile tunnel was not yet opened; while for the greater part of the latter year the shore inlets were entirely closed, and the four-mile tunnel and the one-mile tunnel at Lake View were in use. For the year ending September 30, 1892, the number of deaths from typhoid fever in Chicago was 1,790 in a total of 26,646, or a percentage of 6.72. For the year ending September 30, 1893, deaths from typhoid fever were 712 in a total of 26,977, or a percentage of 2.64. It is most unfortunate for this comparison that the old supplies were partly in use during the first few months of the latter year, before the four-mile tunnel was opened. We may believe that if this had not been the case the comparison would have been still more favorable to the improved supply. It is a well-known fact that people using a water-supply to which they are not accustomed are often more susceptible to any infection which it may contain than are those using such water regularly. A striking illustration was furnished by Philadelphia in the Centennial year, when the typhoid death-rate was nearly doubled, while in Chicago the present year, for the first five months of the Fair period, the rate has been less than half as high as for the corresponding month of the preceding year, and for the entire year under consideration. In spite of the vast numbers of visitors continually present, there has been a reduction of over sixty per cent. in the typhoid fever death-rate. This reduction is most striking, and it can hardly be doubted that the improvements in the water supply have been the chief, if not the only, cause. As there is no marked local distribution of the typhoid fever, so there were no exceptions to the general improvement with better water-supply. Not a single ward but showed a substantial reduction. Stronger evidence could hardly be produced to show the causal relation between the contamination of the water-supply and typhoid fever. The mortality percentages from typhoid fever in a number of cities may be compared as follows: Chicago, 1892, 6.72; in 1893, 2.64; Philadelphia, 1892, 2.22; Boston, 1.22; Paris, 1.01; New York, .90; Brooklyn, .80; London, .49; Berlin, .42. The cities having the lowest typhoid fever death-rate, London and Berlin, use only filtered water. London draws nearly all of its water from the two grossly polluted rivers, the Thames and the Lee, and, after filtering it, supplies it to a population that is almost free from typhoid fever. It may be a question worth considering by the engineers whether filtration would not be as cheap and effective a means of improving the water-supply as the farther extension of the tunnels.

Removal of Pathogenic Bacteria from Drinking-water by Sand Infiltration.—This paper was read by Mr. George W. Fuller, of Lawrence, Mass. That drinking-water is the carrier of some diseases there can be no doubt. Numerous laboratory experiments, by many investigators, indicate that the bacteria generally attributed to be the specific organisms of typhoid fever, Asiatic cholera, and other diseases, live in ordinary drinking-water for many days. The results of long-continued investigations at the Lawrence Experiment Station show that the typhoid bacillus is able to live in the water of the Merrimac River, in greatly diminished numbers, for a period of at least twenty-four days. Other investigators, using different water and different conditions, estimate the length of life of this germ at from three to eighty days. The duration of life of the cholera spirillum in various waters has been observed to be from two days to seven months. Modern hygiene demands that drinking-water shall be free from pathogenic bacteria, and the means by which such water can be obtained are worthy of our most careful consideration.

During the past forty years many filter-plants have been constructed in Europe, and numerous experiments in the filtration of water have been made, particularly during the past decade. This is largely due to the aid of bacteriology, which enables us to determine the actual efficiency of filters with regard to the removal of bacteria. The operation of many filters is quite satisfactory, as is shown by the low death-ratio from these diseases conveyed by drinking-water, and by the results of numerous bacterial analyses.

In summing up our present knowledge upon the removal of pathogenic bacteria from drinking-water, we may state that in addition to the experience of certain European cities, the Lawrence investigations, covering a period of more than five years and including the bacterial examination of more than eleven thousand samples of water, indicate that it is entirely practicable to construct filters that will economically purify water and remove more than ninety-nine per cent. of bacteria which may be present in the unfiltered water.

Dr. Thomas Noriega, of Mexico, read a paper on "The Potable Waters of the Country Presenting many Dangers," and Dr. E. Liceaga, of Mexico, on the "Statement of Scientific and Experimental Data for the Establishment of International Maritime Police." Dr. Domingo Orvanaños, of Mexico, read a paper entitled "Difficulties in the Practice of Quarantine in Some of the Mexican Ports." Other papers were read as follows on this subject: "The Canadian Quarantine System," by Dr. Frederick Montizambert, of Quebec, Canada; "Quarantine System of Texas," by Dr. R. M. Swearingen, of Texas; and "Quarantine," by Dr. S. B. Ollifant, President of the Louisiana State Board of Health.

Evening Session.

At this session addresses were delivered by Dr. Sarah Hackett Stevenson, of Chicago, on "Municipal Sanitation;" by Miss Ada Sweet, of Chicago, on "Voluntary Health and Public Improvement Societies;" a paper by Sir Charles Cameron, of Dublin, on "Importance of Civic Public Hygiene to the State;" "Municipal Sanitation of Minneapolis," by Dr. E. S. Kelly, of Minneapolis; and "The Importance of Sanitary Bureaus, their Economic Organization," by Dr. Jesus E. Monjaras, Sanitary Inspector of San Luis Potosi, Mexico.

Fourth Day, Friday, October 13th — Morning Session.

Papers were read at this session as follows: "The Best Way to Restore the Practice of Vaccination to Its Proper Place as a Preventive of Small-pox," by Dr. Charles N. Hewitt, Secretary of the Minnesota State Board of Health; "Animal Vaccine: Why It Should be Preferred to Human Vaccine," by Dr. Miguel Marques, of Chihuahua, Mexico; "La Grippe," by Dr. Gregorio Mendizabal, of Mexico; "Diphtheria in the City of Mexico," by Dr. Roque Macouzer, of Mexico; "Notes on Scarlet Fever in the City of Mexico," by Dr. Fran-

cisco Marin, of Pueblo, Mexico; and "Unrest," by Dr. William Oldright, of Toronto.

An Experiment in Disinfection: How an Epidemic of Pneumonia was Checked.—This was the title of a paper read by Dr. Jerome Cochran, of Birmingham, Ala. The paper dealt with an epidemic of pneumonia checked by disinfection. The total number of cases during the epidemic was 93; total number of deaths, 30, nearly one-third of the cases. The epidemic occurred in the prison at Pratt Mines, Ala. The prison was divided into three sections, and while the disinfection was going on in one section the convicts belonging to that section were crowded into the other two sections. The mattresses were taken off, and these together with the blankets were scattered over the floor. Then by means of a force-pump and a long hose-pipe the ceilings, walls, and the floors, with their contents, were literally deluged with a solution of bichloride of mercury, 1 to 1,000, until the bichloride solution stood in puddles and ran in rivulets on the floors. The mattresses, etc., were turned over so as to be wetted as thoroughly as possible on both sides. Dr. Cochran has more confidence in the disinfecting power of heat than in the bichloride. The mattresses, blankets, etc., were therefore put into large steam chambers that had been constructed for the purpose, and kept there for six hours, after which they were taken out and dried. In the meantime the disinfected wards were thoroughly scrubbed out, whitewashed, and fitted up so that they could be occupied again the next day. The convicts, before they were returned to their old quarters, were required to take a bath and to put on clean clothes. In one week the epidemic, attacked at the period of its most rapid increase, went out like a fire under a deluge of water.

A Contribution to the Study of Yellow Fever from a Medico-geographical and Prophylactic Point of View in the Mexican Republic.—This paper was read by Dr. E. Liceaga, President of the Superior Board of Health, Mexico. The author presented the following conclusions:

1. The places where yellow fever reigns, and which can be considered as centres of infection are in the Gulf of Mexico, Vera Cruz, Frontera, Campeche, and the districts on the northern coast of the Yucatan peninsula, the last named separated by the Yucatan Canal from the island of Cuba, where the fever also reigns. On the great Pacific coast which belongs to the Mexican republic there is not a single yellow-fever centre.

2. All the Mexican territory on the Gulf of Mexico and on the Pacific coast is well adapted for the disease when imported.

3. Yellow fever has become epidemic in the following places of the coast on the Gulf: Matamoros, Altamira, Tampico, Tuxpam, Papantla, Misantla, Nautla, Alvarado, Goarzavoalcos, Minatitlan, Lagang, and San Juan Bautista de Tabasco.

4. The epidemic has extended into the interior, but never into places situated more than 1,008 metres over sea level.

5. On the Pacific there is not a yellow-fever centre, but it has been imported into the following places: On the peninsula of Lower California, La Paz, Todos Santos; on the continent, Guaymas, Altata, San Blas, Mansanillo, Santiago, Acaponeta, Puerto Angel, Salina Cruz, Tonala Soconuzco, Tapachula and San Benito, and in the interior in Hermosillo and Culiacan.

6. Immunity against yellow fever is obtained after having had the disease in any of its forms. It is possible that this immunity may be lost at times, but it is seldom the case, as it happens with typhus, small-pox, and scarlet fever, which may be had by a person who has had them.

7. The vaccine of Jenner against small-pox, and others which science has discovered, authorize us to look for the one that will prevent the yellow fever. The inoculations against this fever which Dr. Manuel Carmona y Valle has practised with success, should be tried on a large scale, in an uniform manner, in order to be able to find out if they are efficacious. If this experience confirm it, then they should be made compulsory in the countries where the fever reigns. If they should not prove worthy, then the inoculation of blood serum, as proposed by Dr. Sternberg, from persons enjoying immunity, should be tried on a large scale and in an uniform manner.

8. The purification of the drinking-waters used by persons who have to expose themselves to contract the disease should be recommended. The purification of the water used on board the ships leaving or calling at infected ports should be proposed.

9. The sanitation of the places which are yellow-fever centres should be done at once.

10. To prevent, by means of sanitary police measures, the importation of fever into places where it can be developed.

How shall Our Lepers be Cared for? by Dr. Benjamin Lee, of Philadelphia, Pa. He said the State Board of Health of Pennsylvania and the Board of Health of the city of Philadelphia have had some unpleasant experiences with lepers, which had led both of these bodies to appeal to the general government to establish a colony, or colonies, where these unfortunates might be provided with the comforts of home and medical care and nursing, and at the same time might cease to be a menace to the health of those with whom they were thrown in close contact. The United States had only gone so far as to make the affection quarantinable at the sea coast, and to order those found suffering from it on arriving vessels to be at once returned to the ports from which they came.

Dr. Manuel Carmona y Valle, of Mexico, contributed a paper on "Yellow Fever." Papers were also read by Dr. Luis E. Ruiz, of Mexico, on "Typhoid Fever in the City of Mexico;" "Some Reflections on the Infection and Contagion of Typhus Exanthematicus," by Dr. Ramon Icaza, of Mexico; "Registration," by Dr. S. W. Abbott, Wakefield, Mass.

Dr. John H. Rauch, of Chicago, Ill., introduced a resolution to suspend immigration until the epidemic of cholera was over, which, after some discussion, was referred to the Executive Committee.

Election of Officers.—The American Public Health Association elected the following officers: *President*, Dr. E. P. La Chapelle, of Montreal; *First Vice-President*, Dr. Manuel Carmona y Valle, of City of Mexico; *Second Vice-President*, Dr. J. N. McCormack, of Bowling Green, Ky.; *Treasurer*, Dr. Henry D. Holton, of Brattleboro, Vt.; *Permanent Secretary*, Dr. Irving A. Watson, of Concord, N. H.

Place of next meeting, Montreal, Canada, October, 1894.

Note.—Although the gathering was denominated an International Congress of Public Health, very few outside of the members of the American Public Health Association contributed to the proceedings. The bulk of the work was done by the members of the American Public Health Association.

After drafting, introducing, and adopting resolutions of thanks, the President declared the Congress adjourned.

The Testicle in Hereditary Syphilis.—1. The testicles may be affected so slightly in congenital syphilis that it needs the microscope to detect the malady. 2. In a small percentage of cases of congenital syphilis, the lesions of the testicle are such that they can be detected by physical examination. It appears, as a rule, in the first two or three years of life. 3. The globe is chiefly affected; and there is no affection of the prostate, vas, or vesiculæ. 4. The disease is frequently bilateral. 5. Hydrocele is fairly frequent, the swelling is painless, and may be nodular. 6. The enlargement is rarely great. The microscopical appearances are those of inflammation of the fibrous tissue framework of the organ, leading to fibrosis, and, if the disease is not checked, to atrophy of the organ. Gummata are rare.—Carpenter.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 19, 1893.

D. B. St. John Roosa, M.D., President, in the Chair.

Myoma Uteri and Its Treatment.—Dr. Andrew F. Currier read a paper on this subject. After some general remarks, in which he referred to the rapid strides which surgical interference had made in cases of myoma uteri, he took up special modes of treatment. The method recommended by Schroeder, which rested upon the proposition that if the uterine canal were intact, the myoma involving only the muscular structure, it might be removed, and the organ with its functional power be preserved, was applicable in only a limited number of cases at best. The technique was difficult, there was danger from want of drainage, there was liability to recurrence, and, if pregnancy took place, it was likely to end in abortion.

Regarding galvanism, he had studied this method carefully, and could say without bias, unless it were in favor of the procedure, that, while it relieved most of the urgent symptoms, it was never followed by permanent cure, except in a few rare cases where some other explanation was at hand. Moreover, there were cases in which it had provoked forms of degeneration which involved great risk to the health and life of the patient. The attempt to cure by so uncertain a means was not to be recommended as a rule. In fact, the most that had been claimed for the electric method by even its warmest advocates had been a symptomatic cure. But if the symptoms were in abeyance, while the condition which had caused them still existed, one could not say how soon they would again be awakened. He was personally acquainted with a number of cases of recurrence of symptoms, which had been allayed by electricity. Ergot, and medicines having a like influence upon the uterus, if given in sufficient quantity to be of effect might also do harm. He had seen gangrene caused by them.

The main question was, whether the symptoms produced by myoma uteri were of such a nature as to warrant removal of the organ. While the claim might be a just one that this disease seldom caused death directly, yet all must have seen many cases in which the loss of blood and other symptoms had brought the patient to premature death. Insensitive women, more especially negroes and Germans, who led an out-of-door life, sometimes suffered little inconvenience from myomatous tumors of the uterus; but he had never seen an Irish or French woman who did not complain. The legitimate symptoms were hemorrhage, pain, and disturbance of function. The latter related to other organs as well as to the uterus. Spontaneous disappearance of the tumor was rare. An early diagnosis was seldom made. The growth of the tumor was usually slow. While it might diminish in size at the menopause, yet the number of recorded cases was increasing, in which the growth had continued, or there had been change to the malignant form.

Aside from modes of treatment already referred to, Dr. Currier said that curettage might check the flow for a time, but it would return. Galvanism sometimes prejudiced a favorable issue from surgery. All cases of tumor of the uterus should be treated. Regarding removal of the uterine appendages, his own success from this method would lead him to regard it with greater favor than would the general statistics.

The procedure which received chief attention in the paper was total removal of the uterus by the abdominal method, the vaginal vault being covered over by the peritoneal flaps. This was regarded as preferable to leaving any portion of the cervix, since, above the latter, pus was liable to collect, and there had even been sloughing away of the small stump. The advantages derived from the Trendelenburg posture had rendered hysterectomy by abdominal incision comparatively easy and safe. Dr. Currier employed gauze drainage into the vagina. He doubted the propriety of operating on very large tumors. Such patients would almost surely die from loss of blood contained in the tumor itself. He had not seen a case of total extirpation in which the pelvic roof had not become as strong as might be desired. Of course the appendages should also be removed during the operation. There was no more reason, the author thought, why the mentality should be affected after the operation than after the menopause. He concluded by expressing the opinion that in the near future the radical operation would be resorted to more frequently than in the past.

A Bright Future for Hysterectomy in Myoma Uteri.—Dr. William M. Polk was quite in accord with the view that hysterectomy for fibroids of the uterus was destined to be resorted to more frequently. This opinion was based upon the history of other pelvic operations, and upon the marked success which had attended hysterectomy for fibroids recently in this country and in Europe. There could be no doubt in the mind of one who had performed the operation that it was a comparatively innocuous one. At least the time had passed when it could be condemned on the ground of excessive mortality. The only question was, What influence had it upon the woman's health and her usefulness as a member of society? Usually the patients were restored to excellent health, and were enabled to perform their duties with a vigor which was surprising to themselves.

In considering the question of removing the appendages and leaving the uterus, one should bear in mind the possibility of retrograde changes taking place, passing into malignant disease. At present the method of operating lay between total extirpation and amputation, leaving only a portion of the cervix. In spite of the many advantages which Dr. Goffe had claimed for the latter method, Dr. Polk preferred total extirpation. Where a small portion of the cervix remained, pus was liable to collect behind it, and the patients would probably suffer more or less the remainder of life. The pelvic floor would remain in as good condition, as well supported, after total extirpation. He would vary the technique, from that described in the paper, and close the peritoneum over the vault, instead of putting in a drain. The patient could leave the bed in twelve or fourteen days. The Trendelenburg posture was of great value in this operation. The mere size of the tumor should not argue against its removal. The four arteries, ovarian and uterine, could readily be tied in the Trendelenburg posture, so that hemorrhage could be thoroughly controlled even while removing by enucleation large tumors with facets projecting under the peritoneum.

No Treatment Required in Most Cases of Myomata Uteri.—Dr. G. M. Edebohls thought that most cases of fibroma and myoma of the uterus were unattended by symptoms, and therefore required no treatment. That did not mean, however, that in a given case symptoms would not arise in the future and demand treatment. Regarding the risks of an operation, he thought they were no greater than in removal of ovarian tumors. In either case, if complications existed, the chances would be less favorable. As to medicinal means, he would expect no more from them in tumors of the uterus than in tumors of the ovaries. Surgery, embracing electricity and the knife, was the only remedy. Treatment by electricity involved as much anxiety as did total extirpation of the uterus and tumor. Personally, he would prefer to perform hysterectomy. He had even lost one patient by electricity.

Dr. H. J. Boldt mentioned the following points: myoma uteri hardly ever occurred before puberty; the cause seemed to be an irritation of the muscular coat of the small vessels; where a change took place it was usually into sarcoma, although he knew of one case in which the tumor became carcinomatous. Electricity should be regarded as a surgical procedure, and should be tried only in special cases. Martin, of Chicago, and others had in some cases tied the uterine arteries with

good result. After total extirpation of uterus with tumor, Dr. Boldt believed in closing the pelvic vault completely. There was no necessity for drainage, after either abdominal or vaginal hysterectomy. He did not think abdominal hysterectomy would take the place of vaginal. He advised complete extirpation as opposed to incomplete.

Galvanism in Two Classes of Cases.—Dr Joseph E. Janvrin had used galvanism in two classes of cases, (1) where the tumor was small and the patient was under thirty-five years of age; (2) at the menopause. In the latter class of cases he usually resorted to curettage also. He did not believe galvanism ever caused the growths to disappear, but the symptoms might be relieved for months or even for years. Where the tumors were multiple, galvanism and curettage had often carried the patient along to the menopause, when shrinkage was likely to follow. He thought the question, whether it was best to leave a part of the cervix, had not been settled. He had never seen these tumors of the uterus undergo malignant change. True, he had seen them coexist with malignant disease of the uterus, but the fibroids and the malignant affection were quite separate, involving different parts of the organ.

Dr. J. R. Goffe was strongly in favor of operative measures. He could not accept the statement that the entire cervix should always be removed. He had performed supra-vaginal amputation, leaving a small portion of the cervix, eight times, with one death. In Europe the procedure had been resorted to many times, with a very low mortality in the hands of those who had done it oftenest. It disposed of traumatic tissue much better than did total extirpation, and the danger of wounding the ureters was much less.

Dr. A. P. Dudley said we had listened nearly two hours to remarks upon the radical operation for uterine fibroma; he would like to ask, What were the hundreds of physicians outside of New York and a few of the larger cities going to do with their patients? Few of them could be expected to perform hysterectomy, and not all patients could come to New York. True, he must himself be classed among those who believed in radical operation, but he had not found it necessary or desirable to urge it upon the patient the first time he saw her. There were palliative measures which should be discussed as fully as the radical operation. He claimed that Schroeder's method of excision still had a field, *e.g.*, in cases of fibroids in unmarried women who had not passed the menopause, and looked forward to the marriage state. Drain through the uterus. Then there were cases where curettage would relieve the symptoms, especially hemorrhage, for often the cause of the hemorrhage was only a little tuft on the mucous membrane which could be easily removed. Electricity was of benefit in some cases. Surely it must have a place, else Keith, at one time the greatest operator in myoma uteri, would not have discarded operating in favor of electrical treatment. In cases of multiple tumors, Dr. Dudley thought the radical operation called for. Regarding complete or incomplete removal of the uterus, he thought it a strong statement that any measure short of total extirpation should be relegated to the past. He would continue to spare a portion of the cervix, and save the vaginal vault, so long as the method was as easy and as safe as total removal. In general he had abandoned Hégar's operation.

About Electrical Treatment.—Dr. A. H. Goelet said he had had occasion to review the literature of this subject, and he believed the opinion of the best part of the profession was to the effect that, when these tumors of the uterus caused no symptoms, there should be no surgical interference. His personal experience had been largely with electricity, and he could say that there were few cases in which the symptoms could not be allayed by electric treatment. He was, therefore, opposed to removal of the uterus (unless there were some urgent necessity) before electricity had been given a trial by one who understood how to use it. He did not claim that this agent would produce a radical cure, but he did claim that in the majority of cases it would cause a symptomatic cure, and sometimes would cause a decided diminution in the size of the tumor. It had not been his experience to meet with a recurrence of the symptoms, especially not in an aggravated form. In spite of assertions to the contrary, this treatment did not complicate subsequent removal. Indeed, by its influence upon the adhesions, and improvement of the general health of the patient, it made success from subsequent removal more probable. He said that, of course, cases complicated by purulent accumulation in the uterine appendages would not admit of electric treatment. A dispensary was not the proper place for its application.

Dr. Lesser was in accord with the last speaker. He had tried galvanism in eighteen cases, in a hospital, and could say that it was of benefit in many, especially those in which the growth was interstitial. He had not known its use to be followed by renewed growth of the tumor. He had tied the uterine arteries with benefit in two cases.

Dr. Currier closed the discussion. Danger to the ureters during supra-vaginal hysterectomy could be avoided by Stimson's method of exposing these.

The Coroner System.—J. H. Girdner said: The Section of Public Health of this Academy took up the subject of reforming the coroners' office last spring and did some good work. On the subject I desire to offer this resolution:

"*Whereas*, The Grand Jury of this county made a public presentment in the Court of General Sessions on September 29th of the present year, declaring the coroners' office to be 'a cause of embarrassment to the interest of public justice,' and suggesting the adoption in its stead of a law providing for the appointment of medical examiners to make all preliminary inquiries to determine the cause of death in cases requiring official examination; therefor be it

"*Resolved*, That the New York Academy of Medicine heartily indorses this action of the Grand Jury, and urges upon the public and the members of the Constitutional Convention soon to meet in Albany the necessity for a change in the constitution of this State sufficient to allow the Legislature to create a new and better system in place of the present useless and antiquated organization known as the coroners' office; and be it further

"*Resolved*, That the New York Academy of Medicine earnestly calls the attention of the public and the approaching Constitutional Convention to the admirable system of medical examiners which the State of Massachusetts has substituted for the coroner system, and that a committee of five members be appointed by the President of this Academy to press the matter upon the attention of the Governor of the State and upon the Constitutional Convention, the Legislature, and the general public."

Dr. A. Jacobi said that if it was proposed to act upon the resolutions at this meeting, and in their present shape, he must oppose them, on the ground that they had to do with politics and questions foreign to the purposes of the Academy.

After some further remarks, the resolutions were laid over until the next meeting, when a fuller attendance might be expected.

SECTION ON PUBLIC HEALTH, LEGAL MEDICINE, AND MEDICAL AND VITAL STATISTICS.

Stated Meeting, October 30, 1893.

S. T. Armstrong, M.D., in the Chair.

Dispensaries, Historically and Locally Considered.—Mr. Charles C. Savage, President of the Demilt Dispensary and Trustee of the Roosevelt Dispensary, presented the paper. He had found very little in literature of aid to him in its preparation. How could those who were strong mentally and physically best aid those who

were weak and in poverty without destroying self-respect, which was the backbone of character. The duty of the State to care for the chronically incompetent ought not to be doubted. Private charity could best assist persons during temporary need, but it should then cease. The true design of charity was to remove the occasion for it.

The primary intent in organizing a dispensary was briefly defined in the charter of the Demilt Dispensary, namely, to furnish medical and surgical aid to those who were in need thereof, and were unable by reason of poverty to pay for it.

Philadelphia was the first city in the United States to establish a hospital (1786); then came New York, then Boston. Dispensaries in New York City could be divided into three classes. The classes shaded into one another, but were organized on different models for different purposes. 1. The original or general dispensary, whose prime motive was to prescribe medical or surgical treatment for the sick poor—a simple humanitarian system founded on the least expensive plan. The physicians were not allowed to charge the patients a fee, but were expected to devote their services free. At present, however, some of the dispensaries paid the physicians a small salary. No indigent person need suffer without a physician. Maternity cases were not taken. 2. Within the past twenty five years the principal hospitals had established an out-patient or dispensary department. They did not pay visits to patients' homes. It was not certain that their object was so much humanity as clinical practice. They did not diminish the attendance on the general dispensaries. A large supply of material, however, was found, if not created, by their existence, even though the hospitals were located outside the so-called poor districts. 3. Special dispensaries for medical or surgical treatment. In them experience was gained which enabled the specialist to become pre-eminent in his line. While they were an advantage to some poor patients, they were a disadvantage to poor physicians. A fourth class might be made to include dispensaries, etc., connected with homœopathic institutions, but their charitable purpose was not so evident, since they were usually located outside of poor districts. Then there were churches, missions, societies, etc., which gave assistance to those in whom they were especially interested. The system of provident dispensaries in England, which had been established to take the place of clubs, etc., was supposed to encourage thrift and foresight among the poor. They have been praised by some and condemned by others who had investigated them. The plan which had been adopted by most dispensaries in New York, of charging ten cents a prescription, had worked more successfully than had been expected. About eighty-five per cent. of those coming to the dispensaries, and seventy per cent. of those visited at their homes, were able to meet this nominal charge. Probably nine-tenths of the dispensary patients were foreign-born or one remove therefrom. They lived from hand to mouth. The rent of their rooms ranged from three to fifteen dollars a month. Many gave a false address, and many visited different dispensaries, thus multiplying the number of persons apparently receiving charity.

Does Gratuitous Relief Have a Demoralizing Effect on the Recipient, and Does it Interfere with the Emoluments of Practitioners?—On this question superficial thinkers were divided between yes and no. But there were complex problems involved which yet remained unsolved. It was admitted, in discussions in some of the newspapers and medical journals, that dispensaries did a great deal of good, but it was also charged that they did an immense amount of harm by indiscriminate bestowal of gratuitous service. One complainant had suggested an investigation in each case, but Mr. Savage regarded such a plan as impracticable. Moreover, physicians would oppose it, as it would, if carried out thoroughly, result in closing some institutions in which they were interested. Free music in the parks, free libraries, free baths did not demoralize the recipients, nor make mendicants of them, and he thought the same might be said of free medical treatment. The average poor man's doctor was either inexperienced, incompetent, or a scheming quack. The patient's desire was to be cured, and he was anxious to obtain the best service which his poverty would permit. Whatever fault might exist in dispensaries, he thought reasoning philanthropists must regard them as absolutely necessary in a dense community. From forty years' observation, he felt quite sure that dispensary charity was the most healthful and least harmful of a number of ways of assisting the poor; that it acted least toward breaking down self respect and desire to be self-supporting. Physicians competed for positions in the dispensaries. Appointments were made for ability alone, the chief purpose being to help suffering humanity, and only incidentally to benefit the physician. A question which had been much debated was, how should the board of managers be constructed? Should they be laymen or physicians, or composite? Mr. Savage believed they should be laymen, but he did not believe in appointing laymen for social position or wealth when they took no active part in conducting the work of the dispensaries.

Dispensaries had come to stay, for good or for evil, and the fact that they had not received discussion in city, State, and national medical societies was to be deplored.

Dr. J. West Roosevelt, being requested to open the discussion, expressed gratification at having listened to remarks upon the subject of dispensaries by one so eminently fitted to discuss the subject. Complaint regarding the dispensary abuse usually came from certain physicians who felt that improper cases received treatment free. But the question had often been discussed from a narrow standpoint. First, however, let us admit that dispensaries, in spite of the good they do, do a great deal of harm, but not nearly so much harm as those think usually who criticise them. In a large floating mass of dispensary patients, it was impossible to correctly estimate the number receiving free medical treatment. The fact that certain physicians were benefited and others injured by establishing dispensaries, did not affect the question of right in founding them. The public weal, not individual weal, was to be considered. Physicians in dispensaries had for their chief object personal benefit by gaining experience. In teaching dispensaries the instruction obtained from the patient's case should in no wise be regarded by the patient as paying for the medical service. To decide who was worthy of dispensary charity was a difficult problem. Must the person be reduced to absolute penury? He thought not. Appearances could not constitute a basis, for a clerk might be in poverty, and yet be compelled to put on some appearance of thrift in order to retain even a miserable position. There was no comparison between ordinary charity and charity to the sick. The sick seeking charity could not be regarded as vicious or criminal. At the Roosevelt dispensary more than eight per cent. of applicants were rejected simply on their own replies to questions. A charity organization society could not possibly visit all to determine their worthiness of medical aid. He did not believe in "playing pay." The dispensary physician could do a good deal toward eliminating patients who were able to pay, and he should have that privilege.

Glaring Abuses.—Dr. H. D. Chapin said that abuses were particularly glaring in children's dispensaries. He had been connected with four. One evil was that babies were brought out which ought not to be taken out at all. A baby with pneumonia or pleurisy would sustain much greater injury by being taken to the dispensary, than it could receive of good from a prescription for medicine. Then, dispensaries did more toward spreading contagious diseases than all other factors. He objected strongly to boards of managers being composed exclusively of laymen, just as he objected to boards of health which excluded physicians as members. It had been objected that doctors were cantankerous, and would be unfair in

making appointments, etc. It was true that they were actuated more or less by favoritism, as were other men, but he insisted that those who had to treat the sick should have the management of the institutions in which they were treated. Certain improvements would surely follow. At present the work done in dispensaries was worthless from a scientific standpoint. Conclusions drawn from dispensary statistics did more harm than good in medical literature. There should be a laboratory in each dispensary, where blood could be examined for the plasmodium of malaria, etc.

A child was brought to the dispensary with diarrhœa. The mother paid ten cents for a prescription, when the doctor who wrote the prescription knew quite well that good milk was the only remedy. There should be a corps of visitors to go to the homes of the poor and correct the cause of sickness there. Then they could judge of the financial circumstances of those seeking charity.

Dr. F. W. Jackson said he had given a great deal of time to dispensaries for many years. He thanked God that he had not been connected with any which permitted the abuses spoken of by the last gentleman on the floor. He knew it was possible to carry on dispensary work without such abuses. At present, however, there was some danger in most dispensaries of spreading contagious diseases. The plan in vogue in Germany would be desirable, that of having patients seen first by a physician, who should isolate at once those with contagious diseases. He earnestly opposed the view that good scientific work could not be done in dispensaries. A laboratory would be desirable, but it was not indispensable. At Roosevelt they were going to give the sick children good milk at four or five cents a bottle. Perhaps he stood alone in the view that a gift did not demoralize the recipient. He had turned many persons away from the dispensary, telling them they were able to pay a doctor, and they had usually admitted they were. He had been surprised at how many of these persons had gone to the institution because they thought it was a public one, that the attending physicians received a large salary, and that they were desired there as patients. They had no idea they were acting the part of paupers, and went away willingly when he explained to them that they were taking his time, which should be devoted to the poor. It seemed to him the doctor outside had no right to cry. He had not the energy or luck to get in. But the doctor inside had a responsibility which he ought not to shirk. He should never take a patient through his opportunities at the dispensary. He should act fairly to the doctor outside, even though he did not know him. It would be very difficult to have the condition of every patient inquired into, but the dispensary physician could exclude many who were able to pay by a few well-directed questions.

Dr. Joseph Collins had had four or five years' experience with several dispensaries, and spoke warmly against their abuses. One had not been mentioned, namely, the sending of patients by physicians to teaching institutions for the opinion of specialists. As to the value of dispensary work for scientific purposes, he would like one to mention a contribution of worth published within a decade, based on dispensary observation. He believed that if the wealthy people would pay a corps of twenty physicians a small salary, say five hundred dollars a year, and a corps of nurses at eight hundred dollars a year to visit those seeking help at their homes, and enable them to prescribe free milk if it were needed instead of free medicine, more good would be done than was being done by all the dispensaries. Large sums of money were spent upon dispensaries, these were conducted according to old methods, and no note was taken of the advances made in sociology. How many young ministers or lawyers would devote as much time to the poor without compensation as was being done by scores of physicians? The medical profession was a part of the public, and should have something to say in the matter. They were suffering from the condition from which the early American settlers suffered—taxation without representation, and they were about ready to throw over the tea.

Dr. L. Landis said that in a dispensary where he served, one doctor was expected to treat as many as thirty patients in an hour. How much thought could he give to the individual cases? The question of pauperism could not be solved by charity: it could be solved only by treating the cause of pauperism. Dispensaries made paupers. A man, though rich, would not spend a dollar if he could get its value for nothing.

Dr. Leverson, attorney, earnestly appealed to physicians to study the social aspect of the question; to inquire into the cause of poverty, and, apprehending the remedy, seek to apply it. Voluntary poverty would always remain; involuntary poverty was due to the monopolization of the forces of nature by a few through evil legislation. This fact had been demonstrated by the greatest philosopher of centuries, Mr. Henry George, in his book, "Poverty and Progress."

Dr. Dillingham named a dispensary in the city where cases of contagious disease were diagnosed at once and isolated, thus preventing spread among other patients.

Thousands of People Pauperized by Doctors, none by Dispensaries.—Mr. Cook said he had heard a great deal about the demoralizing and pauperizing effect of dispensaries, but he had failed to observe it; he knew of perhaps thousands of cases where people had been pauperized by doctors; cases where land, house, furniture, clothing, had gone to pay doctors. The public spent hundreds of thousands of dollars to prevent disease by keeping streets clean, etc. Was it not worse when disease had actually come? Was it not in the public interest to get the patient well as soon as possible, in order that he might again become a producer? Once we paid twenty or twenty five cents a yard for cloth for which we now pay only ten cents: had the effect of a reduction in price been demoralizing?

The Chairman, Dr. Armstrong, thought the argument of the last speaker not sound. There was a vast difference between spending large sums in the interest of the people when it had been collected by taxation, and asking the services of physicians for which nothing at all was paid. Judging by his experience in the large cities of the United States during the past fifteen years, he thought New York unfortunately cursed with the dispensary system. He believed that one of the most baneful of things in a community was indiscriminate alms-giving, and he saw no difference between indiscriminate almsgiving and indiscriminate free medical treatment. The argument of the paper seemed to be that physicians were working for experience, and were therefore well paid. This argument, he thought, had not the least amount of weight. What man, in any position in life whatever, was not working for experience? Medical men were very necessary to dispensaries, but boards of trustees were utterly worthless He thought something should be done to exclude well-to-do people as dispensary patients.

A lady physician inquired of Mr. Cook whether plumbers could be expected to render services free because they were in the interests of sanitation?

Mr. Cook supposed the public would not object if plumbers should form societies and offer their services free, as doctors did.

Mr. Savage closed the discussion. He did not doubt but what the physicians highest in the medical profession owed their eminence largely to experience gained in dispensaries, and in that way they were in a sense paid for their services. Moreover, giving their time without a salary was a voluntary act. Regarding their occupying a place on the board of managers in some dispensaries, they did, and he did not hesitate to say that they were the worst dispensaries in the city.

The Truly Great Physician is one who never speaks ill of his medical brother. He is dead.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, October 23, 1893.

WILLIAM STEVENS, M.D., PRESIDENT, IN THE CHAIR.

THE meeting was devoted to the election of officers for the ensuing year and to the reading of reports of committees.

Election of Officers.—There was but one candidate for each office except that of censor, others having withdrawn their names. The Secretary was instructed to cast an affirmative ballot for the Society for the following: *President*, Seneca D. Powell; *First Vice-President*, Henry D. Chapin; *Second Vice-President*, Egbert H. Grandin; *Secretary*, Charles H. Avery; *Assistant Secretary*, William E. Bullard; *Treasurer*, John S. Warren. The President declared these gentlemen elected. The candidates for *Censor*, five to be elected, were: A. S. Hunter, C. H. Knight, F. Peterson, R. Van Santvoord, E. D. Fisher, F. M. Warner, W. Stevens, and A. Caillé. The five here first named received the highest number of votes and were declared elected.

Work Done by the Comitia Minora.—Among other work done by the Comitia Minora, mentioned in its reports, was the adoption of a resolution, which had also been approved by the Society, recommending the establishing of a bureau of trained nurses, and appropriating $500 therefor, provided a suitable room could be obtained in the building of the Academy of Medicine.

Regarding the recommendation of the State Medical Society, that all county societies hold their annual (election) meeting in the spring, the Comitia thought a change in the case of this Society was not advisable.

By a by-law of the Society, members of the Comitia who absent themselves from three meetings during the year without an acceptable excuse, are debarred from holding office for a year. Dr. Abbe, who had been nominated for president, having been absent from five meetings, found it necessary to withdraw his name.

Treasurer's Report.—DR. WARREN read his report as treasurer. There was a balance in the treasury from last year, in round numbers, of $1,789. Received in annual dues, $3,228; in initiation fees, $321; fines from illegal practitioners, $2,000. Sale of transactions, etc., brought the sum up to $7,438. The disbursements had been $4,657, leaving a balance in the treasury of $2,781.

Counsellor Purrington's Report.—This was included in the report of the Board of Censors, and was read by DR. VAN SANTVOORD. During the year nineteen persons had been arrested for illegal practice, two cases were withdrawn, in the other seventeen there was conviction. In three of the cases the detective work had been done by newspaper reporters, the expense of the department to the Society above the amount of fines collected had been about $550.

The Annual Dues of members are continued at $3.

Report of the Committee on Hygiene.—This report was read by DR. WILLIAM A. EWING. It referred to the requirements in the handling of manure; to carelessness of the public in drinking from the public cup and of water the purity of which was doubtful; to the handling of ashes and garbage, recommending separate carts and those which were water-tight, provided with a cover, and not to be filled within two inches of the top; to immediate separation of patients with contagious diseases from other patients in dispensaries; recommending more radical measures in preventing the spread of tuberculosis and of syphilis; suggesting that there should be State inspectors in contagious diseases, etc.; approving of the establishment of a national board of health. The report stated that the introduction of cable for horse cars on the Third Avenue line would do away with twenty tons of manure now dropped in the streets daily.

A Member Expelled.—DR. EVERETT HERRICK, Chairman of the Committee on Ethics, sent the report to be read by the Secretary. Recently a member in Harlem had been expelled for evident prevarication in answering to charges of criminal abortion.

Prize Essay.—DR. BRONSON, Chairman of the Committee on Prize Essays, read the report. Five essays had been submitted in competition during the year. The successful one was by Dr. Joseph Collins: "A Contribution to the Arrangement and Functions of the Cells of the Cervical Spinal Cord; to which is appended a note on Central Changes Secondary to Long-continued Disuse of an Extremity."

Honorable mention was made of the essay by Dr. WILLIAM L. BAKER: "Studies on the Streptococci Occurring in the Throat, and their Relation to Other Streptococci."

On motion, the Comitia Minora was authorized to appropriate and apply such sums of money as might be in its judgment required for the successful working of the Society during the coming year.

A motion, requesting the President to appoint a memorialist on the late Dr. John C. Peters, was passed.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS—GASTRO-ENTEROSTOMY AT THE CLINICAL SOCIETY—NEUROSES OF THE MENOPAUSE AT THE MEDICAL SOCIETY—MR. JONATHAN HUTCHINSON AND HIS NEW MUSEUM—DECEASE OF M. A. HENSMAN.

LONDON, November 3, 1893.

YESTERDAY the annual meeting of the fellows and members of the Royal College of Surgeons of England was held, and a dreary function it was. The council mustered in full force, but their audience scarcely outnumbered them. A few years ago, when these meetings were first held, the greatest hopes were entertained, and members as well as fellows looked forward to exercising some influence in their own college. Then the theatre was crowded with members who listened with delight to the eloquence of Sampson, Gamgee, and other supporters of their rights. But the council has held on to its selfish obstruction, and the anachronism remains of a council of twenty-four, retaining in this century all the powers and privileges of a college of some seventeen thousand members. There is a pretence of consulting them at this annual meeting, but the council adopted the policy of simply reporting the following year that they had received the resolutions passed at the preceding meeting, and so exhibiting an object-lesson of how-not-to-do-it. After asserting their claims year after year, the members have become disgusted and no longer come to the meeting, and the fellows are satisfied that their own pretentions will be upheld by the council, and so stop away. Of course, there are two or three interested reformers of each class who put in an appearance, and perhaps half a dozen more whose leisure permits them to look in for once and satisfy their curiosity. And so empty benches face the council, who should learn from this that confidence in them—notwithstanding their friends pass a resolution of thanks—is no longer felt by the great mass of the profession. It is true that some more liberal-minded fellows have obtained a seat in the council, and much is hoped from their influence; but every meeting held proves more conclusively the need of some more drastic reforms—say, such as an act of Parliament would in this democratic age be likely to apply.

Gastro-enterostomy again occupied the attention of the Clinical Society on the 27th ult., when Mr. Bidwell related a case of cancer of the pylorus in a man sixty-nine years of age, for which he had joined the jejunum to the anterior wall of the stomach by Halsted's method. Vomiting ceased at once and the patient survived five weeks, and died of extension of the disease and exhaustion. He

had collected notes of fifteen cases which, with Mr. Jessett's seventeen, give total operations, thirty-two, with nine deaths. Mr. Ballance said in several cases the result was satisfactory for six or eight weeks, but then the opening into the stomach gradually closed. He had, with Mr. Edmunds, experimented on animals, and concluded that Paul's method was the best, a bone ring being inserted, uniting the jejunum with the posterior wall of the stomach, an opening in the anterior wall being made to permit this. He attributed the success to the fact that part of the stomach-wall sloughed away and left a large opening into the jejunum. This opening had not contracted in a large dog after several months. Mr. Symonds had given up Senn's plan in favor of lateral anastomosis. In one case, after using the plates the patient was as bad as ever in five weeks, and he reopened the stomach to find the aperture nearly closed. He enlarged the opening and sutured the mucous membrane at the edges. The opening closed again, so he did a third laparotomy and removed a piece of the gastric wall as large as half a crown. He then divided the jejunum, fastened the cut lower end into the hole he had made in the stomach, and made an opening into the jejunum further down and inserted into it the lower end of the duodenum. A good recovery resulted. Mr. Moullin had operated twice, once with Senn's plates and once with Robson's bobbins. Contraction occurred in the first case and regurgitation in both. Mr. Battle also liked Senn's method. Mr. Haward defended Senn's plates, especially as these cases were usually operated on late and it was necessary to operate rapidly. Mr. Gould had once opened the abdomen in the middle line, united the jejunum to the stomach as near as the growth permitted, then incised each viscus and united their cut edges by continuous silk suture, fixing the parts by a few Lembert stitches. The symptoms were relieved, but the patient died suddenly on the sixth day.

On the 30th ult. the Medical Society had a good subject for one of those chatty debates which seem at home in its rooms. "Some Neuroses Associated with the Menopause," was the title of a paper by Dr. Savage, founded on fifty-four cases of insanity of the "climacteric type." Dr. Richards, with twenty-five years' experience at Hanwell, could not subscribe to the author's view of the importance of the menopause, as the majority of insane women were admitted at an age which rendered it impossible; and even in insanity recurring at menstrual periods, the menopause produced no change for the better, though it substituted melancholia for acute mania. But he even doubted if the melancholy at this time were really due to sexual changes, seeing how that has been for years the prevalent type of insanity. Dr. Althaus said he knew of cases of which no explanation could be given except the disturbance due to the cessation of menstruation, and suggested a study of the mental condition of those who had undergone double ovariotomy. Dr. Griffith protested against this comparison, and said the conditions were not parallel, as at the menopause ovulation and menstruation are not simultaneously interrupted. He did not admit that the menopause could of itself affect the mental powers. Dr. Cullingworth, on the contrary, held that the precocious menopause induced by double ovariotomy was on all-fours with the normal change. He said few women altogether escaped some mental trouble at the menopause, but few came under the notice of the alienist, as they were not of a character to necessitate confinement in asylums. He had never known the removal of obviously diseased ovaries induce mental trouble. Dr. Routh suggested that alienists should systematically examine the reproductive organs of their female patients, but to this Dr. Savage in his reply objected, and remarked that in America, where lady doctors are connected with asylums for this purpose, no useful result has followed. Dr. Richards mentioned the case of a lady who became hopelessly insane after the removal of the ovaries, at the age of thirty three, for local disease, and he was convinced that the removal was the cause of the insanity.

Mr. Jonathan Hutchinson has always something to say, and he usually says it in an interesting manner. His post-graduate course is therefore a favorite one. Then he has during his career always been a collector, so that he has a great wealth of material for study. Again, he has classified his material so as to make it readily accessible. All sorts of facts (as well as specimens) he collected and classified, and twenty years ago it was a joke among his students that on any question they might ask he would take out of his pocket a handful of cards on one of which the answer would be found. This habit of collecting and classifying, inasmuch as his hospital—the London—is the largest in the metropolis, accounts for his wealth of clinical material and his ability to illustrate so many subjects. Wax models, drawings, casts, pickles, sections, instruments, nothing comes amiss to this omnivorous collector, and now he has taken a step which few would dare to do if they had the material. But Mr. Hutchinson is not the man to ask whether his compeers will like it, though he is "cute enough to know that the masses will." He has started a museum of his own in a building taken for the purpose, and there he intends to give his post-graduate course, and there, too, every medical man on presenting his visiting-card will be freely admitted any Tuesday afternoon, and when examining the illustrations will often have the advantage of a demonstration by their owner. His museum looks like a picture gallery of pathology, with a library or descriptive catalogue added. The pictures are set up on narrow ledges, so as to be easily moved and restored to their places. The books are really scrap books, a couple of hundred or more. Their contents are cuttings from journals and pamphlets, carefully indexed. Thus, on a subject for lecture a volume will be found to contain the current literature, and the illustrations are mounted on the ledges ready for comparison. At his regular demonstrations, too, Mr. Hutchinson likes to have living patients. At the last he had a case of congenital ichthyosis, a very severe one of bromide ulceration, and one of Bazin's disease. In a future letter I may give a few notes selected from his demonstrations.

Mr. Hensman, for some twenty years teacher of anatomy at the Middlesex Hospital, died on the 1st inst., after ten days' illness. He presided at the dinner on the opening of the session, though in rather failing health.

A NEW AND RAPID METHOD OF ANÆSTHESIA.

To the Editor of the Medical Record.

Sir: In the number of the Medical Record dated October 21st, there appeared an article with the above given title, by Dr. William S. Magill, of Chicago, in which he claims priority among American physicians in the use of bromide of ethyl for anæsthesia preceding chloroform or ether in major operations; also that "the method was devised and developed during the summer and fall of 1892, by Dr. Bourbon, Dr. Hartman," and himself at the Hospital Bichat.

The claims of originality, as expressed in the article above referred to, seem to lack foundation, as the same method of producing the anæsthetic state was extensively used and discussed thirteen years ago. In the *Medical and Surgical Reporter* of August 7, 1880, was published a paper on "Anæsthesia by Ethyl Bromide," by Dr. H. Augustus Wilson, of Philadelphia, to which was appended an elaborate bibliographical table containing references to the history, physiology, and uses of ethyl bromide, from which the following is an extract bearing upon Dr. Magill's paper: "After complete anæsthesia has been produced by ethyl bromide, I have found it practicable to continue anæsthesia by the use of sulphuric ether, which has the advantage, and at times the disadvantage, of keeping up the anæsthetic state a considerable time after the napkin has been removed."

It has been used quite extensively in this capacity by

Dr. D. Prince, of St. Louis.[1] The late Dr. R. J. Levis, of Philadelphia, as early as 1879 used bromide of ethyl extensively for preliminary anæsthesia when ether was to be used.[2] Dr. E. E. Montgomery has used it in this manner and has so reported at various times, so that Dr. Magill has, in reality, only redirected attention to a method that was formerly and extensively in vogue.

The profession will learn with pleasure the success attending the use of the drug in the hands of Dr. Magill, as it certainly seems to obviate some of the objectionable features of anæsthesia by the use of chloroform or (more especially) ether alone, and this correction is offered in the spirit of "Honor to whom honor is due."

Respectfully,

J. P. Rugh, M.D.

1431 Walnut Street, Philadelphia.

EXTIRPATION OF DISEASED PAROTID GLAND.

To the Editor of the Medical Record.

Sir: Having lately under my care a case of chronic enlargement of the parotid gland, in my search for information upon the subject I observed in "The Science and Art of Surgery," by John Eric Erichsen, with additions by John Ashhurst, M.D., etc., Philadelphia, 1869, under the caption of "Excision of the Parotid Gland," p. 823, the following: "I believe that in most, if not all, the cases in which it is stated that complete removal of this gland has been accomplished, tumors overlying and compressing it have been mistaken for it. It is evident that a diseased parotid gland could not be removed without the division of the external carotid artery and facial nerve."

Dr. Ashhurst's comment in a foot-note is: "So many cases have been reported by competent observers where the parotid gland is said to have been excised, that it is scarcely reasonable any longer to question the possibility of the operation. At the same time there can be no doubt that, as the author says, tumors exterior to the gland have frequently been mistaken for that organ itself, and extirpated by surgeons who honestly believed that they were excising the parotid."

Within the past few weeks a friend, one of the most eminent surgeons of this city, a teacher of surgery, in discussing this question said to me, it was very generally doubted whether the removal of this gland had ever been performed; but with this view he did not accord. I have seen this same doubt expressed in some of our prominent journals latterly.

In my late father's (Dr. Samuel B. Richardson, of this city) note-book of surgical operations performed by him, the following record appears:

"Extirpation of diseased parotid gland. Case No. ——. Mrs. Charles C——, a resident of city of Philadelphia. Married about six years. Leuco-phlegmatic temperament, inclining to fat, and is the mother of several children. Before leaving Philadelphia Mrs. C—— observed some enlargement and hardness, attended with occasional uneasiness and pain, in the region of the right parotid gland. The commencement of the disease was referred to about the year 1836–37.

"In the autumn of 1840 Mrs. C——'s case presented the following conditions: An unyielding, smooth, hard tumor, painful and tender on pressure, considerably elevated above the angle of the jaw, occupied the site of the parotid gland or parotidean region. The most elevated portion of the tumor was about the centre of a line drawn from the mastoid process of the temporal bone to the angle of the inferior maxillary bone The tumor extended upward in front of the ear and elevating its lobe, very like what is observed in acute parotitis when the swelling is greatest. It dipped also profoundly inward between the ramus of the lower jawbone and the mastoid portion of the temporal bone, and was nearly immovable to pressure made at any accessible point or in any direction. The head of the patient was permanently extended on the spine.

"Deglutition, and especially mastication, caused much increase of pain. Uneasiness and pain in the tumor as stated, had been, at intervals, felt since the enlargement was first observed—while these symptoms first led to the detection of the swelling. Within a few months, and especially weeks, the pain had been constant, and at times acute and lancinating, diminishing sleep and appetite, with consequent loss of strength and flesh. No other tumor or swelling found upon neck, or existing elsewhere. No transmitted tendency to malignant or other constitutional or local disease known, and the lady's health had always been good prior to the present malady.

"It should be added that the pain, although greatest in parotidean tumor itself, radiated forward to both jawbones and teeth, upward along the temple to the side of the head, backward to the neck and spine, and down the neck to the corresponding shoulder and arm, nearly paralyzing the latter at times. Few and simple had been the remedies prescribed or used by the patient.

"I informed Mrs. C—— and her friends that I considered the parotid gland as exclusively involved in the tumor, which diagnosis was established by professional friends before, at the time, as well as subsequent to the operation.

"Little if any good could be hoped from medicine—the reluctance of my patient to submit to the extirpation of the tumor advised, induced me, however, to place her upon a free and protracted course of iodine internally, as well as locally employed. This was continued at intervals for months, without appreciable diminution of the tumor. On the contrary, the patient considered the swelling, hardness, and pain as increased and increasing; her sufferings, in fact, were augmented.

"By February, 1841, constitutional irritation had become very great, with a corresponding diminution of appetite, flesh, and strength. Under this state of case, Mrs. C—— solicited an operation as the only alternative. This I consented to perform, first apprising her and her family of the nature and extent of it.

"February 19, 1841, the following operation was performed, with the concurrence and assistance of my friends Drs. Samuel D. Gross, Donne, and T. L. Caldwell, and in the presence of other professional friends and students. The patient was placed on an inclined plane, resting on a mattress, with the shoulders and head elevated, and the latter extended upon the spine. The operation was commenced by making a crucial incision through the skin and cellular tissues over the most elevated and central portion of the tumor. The first incision extended from a point about three-fourths of an inch in front of, and adjacent to, the superior attachment of the ear, downward to about two and a half inches below the angle of the lower jawbone. This cut was nearly vertical. The second was nearly at right angles to the first, with its centre over the greatest elevation of the tumor. The angles thus formed were freely dissected up, and a double hook passed through the capsule into the substance of the diseased body, and handed to an assistant. The skilful employment of the hook was of much service in facilitating the subsequent steps of the operation.

"The temporal and masseter portions of the tumor were first elevated. The diseased body was then drawn forward by the hook, and its connections and attachments adjacent to the concha, cartilage of the meatus externus, ligaments of the temporo-maxillary articulation, digastric and sterno-mastoid muscles, as well as the mastoid process of the temporal bone, separated, keeping the edge of the knife close to the latter to avoid the carotid artery, etc.

"The dissections were continued inferiorly and anteriorly behind the ramus of the jawbone, using the handle more than the edge of the knife, feeling for the pulsa-

tions of the carotid frequently, until this vessel was isolated near its entrance into the tumor. A double ligature was now passed under the external carotid and that vessel tied at two points half an inch apart, and divided between them. With the handle of the scalpel, and fingers mostly, the dissection was continued inferiorly about the deeper attachments of the body of the tumor.

"During this part of the operation the external jugular vein was constantly compressed by the finger of an assistant. The main trunk was not, however, divided."

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 11, 1893.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	22	11
Scarlet fever	59	3
Cerebro-spinal meningitis	4	5
Measles	140	4
Diphtheria	189	53
Small-pox	5	2
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

A Surgeon's Nerve.—It is the common belief that a surgeon must possess what is spoken of as an extraordinary good nerve, and you may perhaps doubt if you possess this. At the same time you must bear in mind that in the case of a surgeon the coolness or calmness which is so admirable and necessary in an operation does not imply the possession of any remarkable personal quality, but it is the simplest result of a complete knowledge of what he is doing. It is rather the natural outcome of his accurate familiarity of anatomy and his daily habit. A trooper would require a very fine nerve to go to a masthead, or a sailor to ride an unmanageable horse across a country; but a sailor's confidence aloft is due more to a matter of habit than to any particular amount of courage. In saying this, I do not wish to depreciate the calmness of the surgeon in the face of difficulties, but I may tell you quite plainly that if you haven't enough courage to be a surgeon I should be very much ashamed of you, and you would turn out to be a very poor creature, whatever occupation you might follow. Still this fact remains, and you may, perhaps, be interested to hear that I, who have known many good surgeons, have never seen one who has not possessed a very fine courage. In short, a very good surgeon is, in my humble opinion, a very fine fellow, and when I see (as I do see) the extraordinary achievements of modern surgery, I am very proud of belonging to a profession which has made life so much more endurable and prolonged to the human race. So, possibly, the great fascination which surgery no doubt possesses to many, appeals more strongly to men of courage and determination than to those persons of more weakly constituted minds, or to those who are less vertebrate altogether.—*Longman's Magazine.*

The First Professional Organization.—Norwich Doctors Wanted a Medical Practice Act in 1774.—The Medical Practice Act suggests the historical fact that the first step toward professional organization and protection in Connecticut was taken by Norwich physicians, March 3, 1774. On that date the following advertisement appeared in reference to the project: "A number of Physicians in the County of New London, taking into consideration the importance of those that enter the practice of Physick being endued with competent knowledge to prosecute the undertaking in such a manner as shall best promote the public good, request their brethren of the Faculty in said County to meet at the house of Mr. Azariah Lathrop, in Norwich, on Thursday the 24th inst., at ten o'clock in the forenoon, to consider upon the matter and prefer a Memorial to the General Assembly at their next Session, that the Practice of Physick may be put under some better regulation." This memorial, which was signed by Theophilus Rogers and ten other physicians, was the first movement toward medical organization in Connecticut. "Quacks and charlatans" had disgusted the regular physicians, and their demand was for the appointment of a committee legally authorized to examine and approve candidates, if found qualified. The movement, which was in advance of the age, was negatived in the lower house; but the memorialists were the pioneers in the cause of American medical organization, and their unsuccessful first attempt was the initiative step in a series of efforts which have since resulted in the permanent establishment of flourishing State and National Associations, which separate the qualified physician from "the ignorant pretender."—*Norwich* (Conn.) *Bulletin*, October 9, 1893.

Inoculations in Typhoid Fever.—Dr. E. Fraenkel reports a number of cases of typhoid fever treated by gluteal injections of cultures of the typhoid bacillus. The virulence of the bacteria was diminished by cultivation in thymus-bouillon. After three days in the warm closet the cultures were sterilized by heating to from 61° to 62° C., and the sterility proved before their employment. The charts and cases are not published in detail, but Dr. Fraenkel is of opinion that the treatment modified and materially shortened the course of the fever, though it did not prevent relapses or accidental complications. The number of cases thus treated was fifty-seven. Professor Rumpf publishes in the same paper thirty-six cases of typhoid fever treated by gluteal injections of cultures of bacillus pyocyaneus. The course of the cases indicated that the treatment had very much the same effect in modifying and in shortening the fever as was produced by Fraenkel's cultures of the typhoid bacillus.—*The Lancet.*

Serum Injections in Tetanus.—Professor Moritz publishes a case of a boy, aged twelve years, suffering from tetanus, treated by injection of Behring's serum. The cause of the tetanus could not be ascertained. The case was a fairly severe example of the more chronic form of the disease, and ended in recovery.

Right to Use Geographical Names for Mineral Waters.—Whether a geographical name may become a trade-mark, when adopted as such, where its owner is the owner of the place of origin, and has the monopoly of the vendible product, is an open question. But where a person alleges title to all the mineral springs situated in a certain place, and the exclusive right to the sale of the waters thereof, and that the name, as applied to said waters, has become of great value to him, and has always constituted an important and necessary incident and means to the sale of said waters, that such a name may be so used, and will be protected against infringement by other persons not obtaining their product from the same locality, is well settled. So says the United States Circuit Court in the case of La République Française v. Schultze, decided July 3, 1893, just now reported, 57 Fed. Rep., 37, where it holds that the word "Vichy," used in connection with mineral waters, and derived from the locality in France where the waters are obtained, is a trade name, or "nom commercial," within the meaning of the industrial property treaty with France of 1883, and as such is entitled to protection in the United States, though it has not been deposited as required by the treaty in the case of trade-marks.—*Journal of American Medical Association.*

REPORT OF SEVENTY CASES OF INTUBATION.[1]

By RICHARD J. STANTON, M.D.,

NEW YORK.

My first practical experience with intubation was through the courtesy of Dr. William P. Northrup. On the evening of October 8, 1886, Dr. Northrup called and asked me to assist him in intubating a child suffering from croup. As I had already read several articles which had appeared in the various medical journals upon the then new operation of intubation, I was very much interested in the subject, and was only too glad to render Dr. Northrup whatever slight assistance might lie in my power. I remember the case very well. It was that of a foundling child of about two years. We could hear the peculiar, typical croupous respiration before entering the room. We examined the child carefully, and found recessions of the chest-walls, absence of vesicular murmur, restlessness, some cyanosis of the lips and around the mouth; in short, it was a typical case of laryngeal stenosis demanding immediate operation. The child was seated in the nurse's lap and the tube was introduced by Dr. Northrup, while I steadied the patient's head. The neatness, swiftness, and skilfulness with which the operation was done excited my admiration, while the immediate relief which the operation afforded was intensely gratifying to us both. The child, which before the operation had been sleepless, restless, and suffering tortures, was, before we left the house, sleeping quietly, the stenosis having been completely relieved. Although this child afterward died, still the success of the operation itself in relieving suffering, even though it failed to save the life, made a profound impression upon me, and I resolved to try it myself at the first opportunity. Since that time I have intubated some 70 cases. Of the 70 cases, 46 terminated fatally, while 24 ended in recovery, the percentage of recoveries being $34\frac{3}{7}$. With but two exceptions, all were tenement-house cases. I mention that fact because I believe that, other things being equal, the tenement-house patient has less chance for recovery than has the private house patient, for the reason that the latter is more liable to have advantages in the way of better treatment, more skilful nursing, and better hygienic surroundings. Of the 46 deaths, 14 were caused by the extension of the membrane to the bronchi, 5 were caused by sepsis, 4 each by asphyxia and pneumonia, 3 by uræmic convulsions, and 2 each by exhaustion, pulmonary œdema, nephritis, and bronchitis.

In the four cases which died of asphyxia the causes were as follows: Case 52, the tube was inserted all right but did not relieve the dyspnœa; in fact, instead of being relieved it became worse, so much so that the tube had to be taken out. I have no doubt that in introducing the tube some membrane was carried down before it, thus increasing the difficulty it was sought to relieve. This was a boy five years of age and among the vilest and filthiest surroundings, with parents as ignorant as beasts. The boy had been abandoned to die by his attending physician, and as a last resort I was sent for. Just as I entered the room where he was, he was vomiting up a mess which I was told was beer and bretzels which he had been eating. On inquiring about the boy's urine, the mother declared that he had passed none for two days, while the father declared it was but one day. As the intubation did not seem to help him, I proposed to the parents to have him sent at once to the Willard Parker Hospital, where he could be tracheotomized, as I would not think of performing it amid such surroundings; but the parents declined the offer, and the little sufferer died a few hours afterward.

Case 53 was very much similar to the one just described. The fauces were filled with a soft, friable, pultaceous mass of diphtheritic membrane, and when the tube was inserted it was not followed by any improvement, so was soon taken out. The surroundings were not encouraging for the success of a tracheotomy, the bare mention of which seemed to be quite enough for the parents. That child also died after a few hours.

Case 58 I left doing very well after the intubation. I had left the string attached to the tube, as I suspected loose membrane. When I next heard of the case the child was dead. It had pulled the tube out and had died before the parents notified the attending physician.

Case 63 was somewhat similar to the above case. Child was intubated at 11 P.M., leaving string in tube. At six o'clock next morning I was sent for, and found the boy moribund and all but dead on my arrival. I inserted a tube at once, but the boy did not rally and died in a few minutes. I was told that he had quieted down and slept nicely after the intubation, but at one in the morning he had pulled the tube out, fell asleep again, sleeping until five o'clock, when the dyspnœa returned and progressed so rapidly as to cause death within an hour. I was very much disappointed at the outcome of this case, as I had regarded it as a very favorable one. I have mentioned these cases in particular because they were interesting in themselves, and because one does not expect his cases to die of asphyxia in intubation unless something unusual occurs.

The greatest number of deaths were caused by the extension of the membrane to the bronchi. That occurs in tracheotomy as well as in intubation, and would occur more frequently in cases not operated on, were it not for the fact that the latter cases are choked to death before the membrane has time to reach the bronchi.

Of the two cases who died of pulmonary œdema, one I place in the column of failures with very great reluctance, because I feel as if it ought to be recorded as a success, as it did not die of the original sickness. It is Case 2, an Italian child aged three years and ten months, intubated January 5, 1887, with immediate and complete success, as far as relieving the dyspnœa is concerned. The child progressed favorably with no bad symptoms until January 12th, when the tube was extracted, leaving her with a normal pulse, temperature, and appetite, and feeling apparently well. Four days later I was again called to find her lungs œdematous and her general condition very bad. She died next day. I believe the œdema was caused by paralysis of the respiratory muscles which had set in suddenly, paralysis of certain muscles or sets of muscles being not unusual after diphtheria. Of the cases operated upon, 42 were males and 27 females, there being one case whose sex I did not get. Fifteen males recovered, about thirty-five per cent., while 9 females recovered, about thirty-three per cent. Their ages ranged from ten months to seven years. The youngest successful case was fourteen months, the oldest was six years; the average age of the successful cases being about three years and five months. Of the cases intubated three were afterward tracheotomized.

70	Aug. 25, 1893	T. J. Larkin.	F.	4 yrs., 4 mos..	12 hours..	7 days	Not examined.	.....	.....	Died on operating-table (tracheotomy).

Case 38, intubated February 28, 1890. Did very nicely until the evening of March 4th, when I was called at 7.30 P.M. and found him again suffering from severe dyspnœa, with chest recessions and the usual train of symptoms caused by laryngeal stenosis. On listening, the flapping of a piece of loose membrane could be distinctly heard against the lower end of the tube, acting as a valve, opening on inspiration and closing the tube on expiration. The tube was immediately extracted and the patient given whiskey to excite coughing, with the hope that it would cough up the loose piece of membrane; it was also given an emetic, but in vain; in five minutes it had grown frightfully cyanotic, and it was deemed wisest to reintroduce the tube, which was done with the result of again relieving the dyspnœa. The string was left in this time and instructions given to pull the tube out should any necessity arise for it. At 8.30 next morning Dr. James L. Bailey, the attending physician, called on me and reported that the child had done fairly well until on toward four o'clock in the morning, when it was again seized with a severe attack of dyspnœa, followed by cyanosis and necessitating the extraction of the tube; it did not rally very well and was then nearly dead. The child had coughed up no more membrane, so I concluded that it was the loose piece which we had heard the day before which was causing all the trouble. I advised immediate tracheotomy and was sent for as soon as the consent of the parents could be obtained for the operation. The child was cyanotic and all but dead as it was laid on the operating-table, and twice during the operation the knife had to be laid aside to perform artificial respiration, as breathing had ceased entirely. After the trachea was opened and the tube inserted, artificial respiration was kept up for about ten minutes before the child had recovered enough to breathe without assistance. We left him breathing softly and naturally, and feeling much better, as he said himself. Five hours later I was sent for in haste, and on my arrival found Dr. Bailey trying to check a hemorrhage which had suddenly developed in the throat wound; in spite of our efforts the child was dead in a few minutes, the blood having run into the trachea and strangled the child. It was a very disappointing end to what I had begun to consider a very hopeful case. I omitted to mention that on donning my overcoat after the tracheotomy, I found clinging to it a piece of fresh, tough, diphtheritic membrane about the size of a silver dime, which had been coughed up when the trachea had been opened, and thrown clear across the room to where it was found on the coat. This piece of membrane was the undoubted cause of all the recent trouble. On thinking over this case I must say, that I do not remember why I did not again try intubation before resorting to tracheotomy. In the light of my later experience, I believe that I should have done so.

Cases 69 and 70 were also tracheotomized. One case was a most malignant case of diphtheria, both nasal, pharyngeal, and laryngeal. It was a child aged twenty-two months, the glands of the neck were immensely swollen, the opening to the throat completely occluded by the inflamed tonsils which met in the middle, while the whole fauces were covered by a foul mass of putrescent membrane. The attending physician, Dr. Edward Fleming, had recognized at once that it was not a favorable case for intubation, and that tracheotomy would, no doubt, do more for it. While we were making preparations for the operation the child to all appearance died. Its eyes were set and glassy, respiration had ceased entirely, and there was no pulse to be felt at the wrist. I must confess that I felt just a trifle relieved at this, for it was a hopeless case at best, and it almost seems as if it is merely bringing an operation into disrepute to operate in such hopeless cases; however, I bent down to listen to the heart and detected some faint flutterings of that organ. Thrusting my fingers into the child's mouth and pulling the tongue forward, the child gasped, and immediately I began artificial respiration, while Dr. Fleming got a tube ready to introduce. In my hurry I did not attach a thread to the tube, and in attempting to get it into the larynx, I got it into the œsophagus and lost it, thereby illustrating the old proverb, the "more hurry the less speed." Fortunately, I had another tube of the same size which Dr. Fleming very speedily had threaded and ready to introduce. This time I was more successful and got it in at once. In the meantime artificial respiration had been kept up, but with no aid from the child. After a few minutes we had the satisfaction of feeling a slight return of the pulse at the wrist. It then received several hypodermics of whiskey which served to increase the heart's action; however, with all our work the child was not able to keep up respiration if left alone, the epiglottis would drop back over the aperture of the tube, and besides there was no place for the air to get through as both the nares and fauces were completely occluded. It having been necessary, while practising artificial respiration, to keep the finger constantly in the child's mouth and by crowding aside the swollen tonsils thus provide a small space to admit the air. As we had gone so far, we decided to carry out our original intention and perform tracheotomy. We sent for chloroform but did not use it, as the child was in as complete a state of anæsthesia as could be produced by artificial means. Owing to the swollen state of the surrounding parts, it was not an easy matter to get to the trachea and introduce the tube, but finally both were accomplished to our complete satisfaction. After a while respiration began to be established, and before we left the house the child was sleeping as softly and peacefully as if nothing was the matter with it. Its color had returned and its pulse was quite strong. At six o'clock the next morning I was called to see it, Dr. Fleming being engaged on another case. I found the child's neck enormously swollen and a temperature of 105° F. It had slept well until about 3 A.M., when it began to get restless, and continued so until my visit. It had succeeded in swallowing some milk out of a bottle in the meantime. The respiration was perfect. I gave it a little tinct. opii. deod. and some digitalis to quiet it. At 11 A.M. called again with Dr. Fleming, and we found the boy resting somewhat easier, but taking less nourishment. At five that afternoon it died of sepsis, the malignancy of the disease having proved too much for it, after having lived some twenty-six hours after the operation. It was a very interesting case. I had heard, here-

tofore, some very improbable yarns about dead children being brought back to life by doctors, but after my experience with this case I felt as if I could believe almost anything.

The third case which demanded tracheotomy was in the practice of Dr. T. J. Larkin, and was a little girl four years and four months of age. The introduction of the O'Dwyer tube was not followed by any signs of relief, because I think that the membrane was too far down in the trachea. It was then decided to tracheotomize. The condition of this little patient was pitiable in the extreme; in its efforts to obtain air it tore its little shirt from its throat and handfuls of hair from its little head. It was put at once under the influence of chloroform, and the trachea reached and opened as soon as possible. There was but very little blood lost during the operation, in fact almost none to speak of, and yet almost immediately after the trachea was opened the child ceased to breathe, and although we tried artificial respiration vigorously for some time, we never succeeded in getting it to give a single gasp. It was as dead as if struck by lightning. What the cause was I do not know. I do not think that the chloroform had anything to do with it, as it was in capable hands and was carefully given. It may be that, as the trachea was opened the child took an inspiration and drew into the lungs a piece of membrane which might have become detached through the operation, thus cutting off respiration at once and completely; or it might have been due to heart failure pure and simple. Whatever the cause, it was a very distressing and embarrassing accident to have happen under the circumstances; however, we had done our duty as we saw it, to the best of our ability, and had nothing to reproach ourselves with.

In regard to the numerous accidents, both theoretical and practical, which are said to be peculiar to intubation, on looking over my list of cases I must conclude that I have been singularly fortunate in escaping most of them. Some, however, I have experienced. In three cases the tube went down into the stomach instead of the larynx. One of these has already been detailed as a tracheotomy case. Another was that of a boy three years of age, whom I saw in consultation with Dr. H. M. Cox. I had introduced the tube, but was not sure whether it was in the larynx or not. I left the thread hanging from his mouth, and on turning away my head for an instant the thread disappeared like a flash and the boy had swallowed the tube. I introduced another and the boy went on to recovery. The wandering tube was passed on the fifth day, none the worse for its journey.

The third case was also that of a boy four years of age. I had passed the tube into the œsophagus, and on attempting to pull it out the thread broke and the tube was swallowed. Another tube was immediately introduced, but the boy died two days ten hours after the operation. The tube was passed the second day after being swallowed.

Tube swallowing can be avoided by the exercise of ordinary care on the part of the operator, but it is an accident of but little consequence anyway, unless one has no other suitable tube at hand to replace it. A more serious accident is the falling of the tube down through the ventricular bands into the larynx. One case of that kind happened in my practice. The case was a very interesting one, and its recital will no doubt prove instructive to those practising intubation. On the morning of November 21, 1890, I was called to see a twenty-one months baby living in a tenement-house on 106th Street. It had been sick for four days, and on my arrival I found that the sickness had already progressed so far as to demand instant surgical interference. With the assistance of Dr. Edward Fleming the child was intubated at noon and the distressing dyspnœa at once relieved. The child was also put on $\frac{1}{48}$ grain hourly doses of bichloride of mercury. At seven o'clock that evening I saw the patient again. Its temperature was 102° F.; respiration 64, and unobstructed; but the lungs contained many moist râles. Next day (November 3d), I was told that it had had a fairly good night. It was looking better and the temperature had gone down to normal, with the respiration 34. It was taking a reasonable amount of nourishment also. I believe it was still nursing. The bichloride was continued. On the 4th, at my visit, was told that the child had a rather restless night, its temperature had gone up to 100.5° F., respiration to 44, but free and easy, and lungs still pretty full of râles. On the 5th, it had a much better night, respiration perfect with lungs clearing up, and a temperature of 100.5° F. still. November 6th, saw it in about the same condition, sleeping very well and improving in its general condition, which it continued to do on November 7th and 8th, although its temperature still stayed at 100.5° F. On the 8th, I concluded to take out the tube, and with the assistance of Dr. Fleming, attempted to do so. The tube had then been in just six days. I made several ineffectual attempts to get it. All at once I became aware, to my horror, that I could feel no signs of the tube whatever under my finger. That was an extremely unpleasant discovery. I probed again in through the glottis with the extractor, but could feel no signs of a tube. I then told the mother that I thought we would postpone further operations until the next day, as I did not wish to tire the child too much. I left the house in no easy frame of mind, and very much provoked at myself at my want of skill. I was in a quandary and scarcely knew what to do about it, but at once sought the advice of Professor O'Dwyer. After I had stated the case to the doctor he smiled very significantly, and asked if I was sure that the tube was in the child's throat, reminding me of a time when I had called on him on a similar errand, thinking the tube had slipped down into a child's trachea, when it was afterward found under a bed, where it had been thrown by the child who had coughed it up. I assured the doctor that this time there was no mistake, that the tube was surely in the child's larynx and I could not get it out. His advice was to leave it where it was and await developments, at the same time kindly assuring me that he would be glad to help me in case I needed any assistance. I called that evening on the patient, and found it in excellent condition, with temperature normal and respiration perfect, and taking nourishment without any difficulty. It coughed now and then, however, and the cough had that peculiar metallic sound denoting the presence of the tube in the larynx. The next day, November 9th, I called at nine in the morning and learned that it had passed a very good night, having slept well. Its condition was good, temperature normal and respiration perfect, and lungs free from râles. At nine that evening the mother of the child called on me, saying that she thought the child had grown considerably worse, that it had coughed much more frequently, and seemed distressed for lack of air. I visited the child at once and found him sleeping, but the respirations were 40 a minute, and there was dyspnœa with recessions of the chest-walls. The temperature was 102¼° F., and the pulse was of that peculiar nature that one gets where respiration is obstructed from any cause, where it seems to be drawn away from the wrist at each inspiration. I sent for Professor O'Dwyer at once, who was kind enough to respond immediately. At first he was rather sceptical about the presence of a tube in the throat at all, for the cough and breathing had lost that peculiar metallic vibratory sound which it had hitherto possessed. The reason for that was that the tube, which before had hung loosely in the larynx, was now wedged down tightly by force of gravity and by the swelling of the surrounding tissues, so that it had lost the power of vibrating. However, the doctor quickly prepared another tube, and placing the child in position, had the old tube out and the new one in in less time than I take to tell it. It was the most skilful and dexterous performance that I have ever seen, its lightning-like rapidity resembled a sleight-of-hand performance more than anything else. In a few minutes more the baby was again asleep in its cradle with all signs of dyspnœa gone. The

thread was left in the tube this time to guard against any further mishaps. On my morning visit next day, November 10th, I was told that he had had a very good night, sleeping most of the time, respiration full and easy, temperature 101.5° F., and lungs apparently normal. He was getting no medicine whatever at this time. On the 11th, I was told that the child had pulled the tube out at eleven o'clock the previous evening, but it had had a fairly good night nevertheless, although the respiration was not unobstructed. At this visit I found some crepitant râles at the base of the right lung. On the 12th, I found that the child had had a restless night, its temperature was 101¾° F., and respiration 60 a minute. There was dulness over the base of the right lung, and it had developed a frequent croupy cough. I ordered a stimulating cough mixture and had the lung poulticed. There was also some laryngeal obstruction at this time. At 3 P.M. I was sent for, the laryngeal stenosis having increased so much that it was now as bad as it had been originally. There was nothing to do but to reintubate, which was done at once, which relieved the dyspnœa immediately and completely, and shortly after the child fell into a sleep. At my evening visit the child was still sleeping quietly. Next morning I learned that the tube had been coughed out at nine the previous evening, but that the child had slept good nevertheless; there was still some laryngeal stenosis, but not marked enough to need a tube. This gradually wore away. From this time on, that is, from November 13th to November 19th, the case resolved itself into one of simple pneumonia, from which it recovered without any serious complications. The chief point of interest in this case, to my mind, is that it shows with what ease damage may be done to the structures in the mouth, without the operator being aware that he is using any force. While searching for that tube I was under the impression that I was using no more force than was usual, and yet I must have stretched the ventricular bands and the vocal cords to such a degree as to let the tube drop down between them into the larynx. The damage was caused by the withdrawal of the extractor while the blades were open. Such an accident could not now happen, as the extractors are now made with a screw which prevents the blades from being opened any wider than necessary. The damage done to the vocal cords in this case left no permanent effects, as the child—he is now nearly five years old—speaks with a perfectly clear, normal voice. The secondary laryngeal obstruction present in this case while the tube was in the throat, was caused by the swelling of the vocal cords over the mouth of the tube, thus occluding its lumen.

Of the other accidents and dangers peculiar to intubation it is hardly necessary for me to speak, because they have been dwelt upon at length by other writers, and most of them to a greater extent than their importance deserves. I believe in several instances, while introducing the tube, I have pushed down membrane before it, but it has never resulted seriously, withdrawal of the tube being always followed by either a coughing out of some membrane or an improvement of the respiration.

Case 21, intubated November 21, 1888, was one of this kind. I saw the case in consultation with Professor O'Dwyer. On insertion of the tube respiration was totally suspended. I pulled the tube out at once, and clinging to the lower aperture was a piece of tough membrane the size of a dime. When that was expelled respiration improved at once, so much so that it was decided to leave out the tube until more urgent symptoms manifested themselves, which was the case fourteen hours afterward. The tube was again inserted, with immediate relief. It went along very well, having a fairly good night, until the next morning at eight o'clock, when it suddenly died. I was told that it was sitting up in bed playing with a drum when it fell back and died at once. I got the tube and found nothing in it, so it has always been a question of doubt with me whether the cause of death was from sudden obstruction of the tube from loose membrane at its lower end, or whether the cause of death was heart failure consequent on the virulence of the disease. It was a malignant nasal case with urine loaded with albumen. Professor O'Dwyer advised me, in case I had to reintubate, to leave the thread in so that it might be removed at once in case it became obstructed. I neglected to follow that advice, perhaps if I had followed it the result might have been different. The question of leaving the thread attached to the tube or not is one which gives me deep concern at every case. One rule will not answer for all cases. In some cases I leave the thread in, giving instructions to the nurse (who is usually the mother also) to pull it out should the child show signs of choking. I find that parents cannot be trusted in the matter, their fears render them incompetent as judges as to when to draw the tube out, and usually they will pull it out whenever the child has a coughing spell of more than usual severity. If the attending physician were notified in time to reintubate it would not matter, but they are not, and I have already mentioned two cases where I think death has taken place for that reason. Also, in some cases, if one desires to leave the thread in the patient's hands must be tied, and that is something I extremely dislike to do. I have done so several times, and in three cases have the little patients gnawed through the thread, and I have found the loose end down in the œsophagus. When this occurs the tube must be removed at once and the thread taken out, otherwise it is but a question of a short time when the tube would be worked up by the thread and swallowed. Some fasten the thread on a tooth or between the teeth so as to prevent its being bitten through; I have never tried it, but think it might be a good plan. In the majority of cases, however, I really feel safer if the thread be taken out at the time of the operation. The greatest drawback to intubation, in my opinion, is the difficulty of its performance. Speaking of my own individual experience, I do not think it an easy operation to perform in all cases. One writer says, "The tube should be introduced quickly and at the first trial." So it should. But how many operators can do so in every case? I venture to say not one. Operators are not born, they are made, and the operation must be performed many, many times before one can feel at home in it. I am more impressed with that fact every time I operate, and if I go two or three months without a case I feel it at once at the next case, and for that reason I think it a good plan to utilize every opportunity to operate, either on the cadaver, on the lower animals, on a larynx stuck in the mouth of a bottle, or any other way whereby one may keep himself in practice. Within the last two years I have had two cases where I could not introduce the tube. I tried as long and as often as I thought safe, and had to give it up. Tracheotomy was proposed and refused, and the poor little patients died. Strange to say, with but one exception, those two cases were the only ones where I intubated or attempted to intubate without the presence of another physician. It is a rule with me never to intubate unless with another medical man, not even in my own practice, unless, of course, the symptoms are so urgent that the delay would prove dangerous. There are many reasons for this which will suggest themselves to everybody. I have never refused to operate in any case, no matter how far gone. As long as there is breath in a patient's body it is not entirely too late, although of course it is neither wise nor proper to defer the operation too long, as by so doing justice is done neither to the patient nor to the operation. In three cases have I been called by the attending physician to intubate, but because I could not assure the parents that the operation would save the patient's life, permission to operate was refused. These cases all died. I was also called in to intubate five or six other cases, but did not consider the symptoms urgent enough to demand operation. Three were cases of spasmodic laryngitis. I believe these cases all recovered without operation. I am sure that not one of the seventy cases would have recovered without operative procedures. As for the technique of intubation, the instruments used and the indications for the operation, it

is not my purpose to speak, as there has been so much written upon these subjects that I am convinced that my hearers know all about them. In regard to the length of time to leave the tube in, it is my custom to be guided entirely by circumstances and the state of each individual case. When the general condition is much improved, the temperature down to normal, the pulse down, the tongue cleaner, and the tonsils and fauces cleared of membrane, then I take out the tube, regardless whether it is the third or thirteenth day. It will be noticed that most of my successful cases wore their tubes quite a length of time, especially my earlier cases. One reason for that is that I did not deem the operation such a light affair, and as long as the patient seemed to be doing well I preferred to leave the tube in a day or two longer than might be necessary, rather than run the risk of being compelled to reinsert it. As for feeding, I formerly used rectal alimentation as a routine practice in all my cases. I have long since given that up, as I found that it was not necessary. I have now no difficulty on that score, as most children swallow semi-solids with but little difficulty, and I have never yet seen any evidences that food goes down through the tube into the bronchioles. Liquids do go down in the tube but are immediately coughed up; but if the child be placed with its head lower than its body and made to drink in that position, and in that position only, then there will be no trouble experienced from liquids getting into the tube.

As to the relative merits of intubation and tracheotomy, I do not propose to enter into a discussion of that question here just now, but will simply state my opinion, founded upon the experience herein given and other experiences with tracheotomy not here given, that for many reasons I prefer intubation. Tracheotomy still has its field, but that field has become very much circumscribed since the advent of the newer operation. Where formerly 20 cases would require tracheotomy, at the present time 19 of those cases would be intubated, while the twentieth case, for some special reason, might still demand tracheotomy; but whatever the operation, whether that of intubation or tracheotomy, I earnestly contend that all cases of laryngeal stenosis which are threatened with death from suffocation ought to be operated upon. In the issue of April 24, 1886, the MEDICAL RECORD began an editorial on intubation with this statement, "The question of operation in croup or laryngeal diphtheria may be said to be yet 'sub judice.'" Whatever truth that statement may have contained in 1886, it would contain absolutely none, in my opinion, were it made in 1893. Nowadays, intelligent medical men are as a unit in favor of operation in those cases, and indeed I cannot conceive how it could be otherwise. Here is a little patient suffering the dreadful agonies of strangulation, its little chest rising and sinking with each vain effort to get air into its lungs; beads of perspiration standing on its forehead; its eyes starting out of its head from the awful suffering it is undergoing—suffering which is depicted in every line of its features; its little hands clutching at its throat as if to tear out the obstruction which it knows is there. This is the picture which confronts the medical man. What is he going to do about it? He has already tried atomizers, sprays, and steam from slaked lime, water, turpentine, etc. He has already tried calomel sublimation, but in spite of all, the dreadful agony still goes on unabated and unrelieved. Will he tell the parents that there is nothing more can be done and abandon the child to its terrible fate? I am sorry to say that my list contains several cases abandoned in just that way, cases that afterward recovered, too. If the medical man is intelligent, competent, conscientious, and not heartless, he will do nothing of the kind. He will propose operation, depicting its advantages and its shortcomings to the parents. They will decide, and the medical man will have done his whole duty. Even should the patient die it is certainly spared much suffering through an operation.

The latest report of any large number of intubations, I believe, is that of Professor Waxham, late of Chicago, now of Denver. Before the Colorado State Medical Society meeting of this year he reported 466 cases, 161 of which ended in recovery, being a percentage of 34½. Surely, that is encouraging. Also, in November of last year, Drs. McNaughton and Maddren, of Brooklyn, gathered statistics of 5,546 cases of intubation with 1,691 recoveries, or 30.5 per cent., and 2,417 tracheotomies with 586 recoveries, or 24.2 per cent. Those figures, I think, show pretty plainly whether those cases should be operated on or not.

I have endeavored in the foregoing report to give my own individual impressions and opinions of the value of intubation in cases of laryngeal stenosis, those impressions having been gathered from my own personal experience, unbiassed and unprejudiced by the experience or opinions of anybody else; and whatever may have been the experience of others, mine has been quite satisfactory to me, all things considered, and I expect to go on intubating as often as suitable cases present themselves until some better method of treating these cases makes its appearance.

In conclusion, as this is my first contribution to the literature of intubation, this report would not be complete did I fail to express my high appreciation of the services rendered to suffering humanity, and to that part of humanity least able to bear suffering, little innocent children, by the illustrious discoverer of intubation, Professor Joseph O'Dwyer. I believe that the alleviation of human suffering is the highest object to which the talents of man can be devoted, and I believe that the success and usefulness of our lives are to a great extent measured by the amount of human suffering which we have been the means of alleviating. Measured by that standard, what a magnificent success is the life of Joseph O'Dwyer, and what a feeling of benign satisfaction must be his as he reflects on the lives saved and the sufferings ameliorated through his instrumentality. No one who has seen a typical intubation, where a suffering, strangling child is, almost in an instant, made free from suffering; no one who has seen that change can repress a tribute to the man whose genius has made that transformation possible. Personally, I am under deep obligations to Professor O'Dwyer, whose ever ready advice and assistance has been of the utmost value to me in many perplexing situations, and I take this opportunity of acknowledging my appreciation of those many kindnesses and returning my sincere thanks. I also wish to acknowledge my obligations and return my sincere thanks to the medical gentlemen through whose courtesy I was permitted to operate on these cases.

Diarrhœa Caused by Infusoria.—Of the four cases reported by Dr. Roos, of Kiel, of persistent diarrhœa, the first was due to megastoma entericum and trichomonas intestinalis; the second was caused by balantidium coli; the third by cercomanos homanis; the fourth was produced by a moderately large infusoria which has not yet been described, but could be compared to the oxyuris in form. The fifth case of intestinal catarrh was complicated with retarded action of the intestines; there were found besides the trichomonas intestinalis and megastoma, those described by R. May. After continued and regular doses of calomel, the infusoria were killed and the intestinal catarrh cured. The author does not consider the infusoria as a direct cause of the intestinal catarrh, but feels that they are, in a measure, the cause of the long duration of the diarrhœas.—*The Medical and Surgical Reporter.*

The Mission Ship Albert returned a few weeks ago from Labrador, where it has been cruising during the past summer. The ship carried three physicians, who treated 2,250 patients in Labrador. They also established three hospitals in that desolate region. The natives showed their appreciation of the services rendered in every possible way, and begged that the steamer might be sent again next year to their coast.

A SYMPHYSEOTOMY: THE TROUGH-BED A SIMPLE DEVICE TO KEEP THE JOINT-SURFACES IN APPOSITION: THE RELATIONS OF THE PERITONEUM TO THE JOINT.

By ROBERT L. DICKINSON, M.D.,

LECTURER ON OBSTETRICS AND ASSISTANT OBSTETRICIAN TO THE LONG ISLAND COLLEGE HOSPITAL; OBSTETRICIAN TO THE KING'S COUNTY HOSPITAL.

L. L——, aged twenty-nine, Italian, married, height 141½ ctm. (55¾ inches), in good health, had been delivered of a living child after a difficult labor, six years ago, the child being probably a small one. Unwell last, ten months ago, in August, 1892. The pelvic measurements are: inter-cristal, 26 ctm. (10¼ inches); inter-spinal, 21 ctm. (8¼ inches). External conjugate, 17 ctm. (6⅝ inches); diagonal conjugate, 10½ ctm. (4⅛ inches); true conjugate, 8 ctm. (3¼ inches). Cavity of pelvis generally contracted. Height of fundus, 25 ctm. (9⅞ inches). Estimated size of head, above average.

June 11, 1893, 9 A.M., pains began with fair vigor, continuing with moderate intervals until June 12th, 9.30 P.M., when the os was fully dilated, but not obliterated, the membranes protruding, the head not engaged, and the pains vigorous. All attempts at crowding the head into the pelvis were ineffectual, and a relative disproportion was evident.

June 13th, at 3.30 A.M., the patient having been 42½ hours in labor, symphyseotomy was performed. The incision was made about 1½ ctm. (½ inch) to the right of the median line, because the joint was felt at this point. The joint was readily followed, the finger being placed behind it, from above downward, with a blunt-pointed bistouri, in preference to my Galbiati knife. The bones were separated after incision of the thick tendon above, the head was pressed down into the pelvic cavity, and the forceps applied, delivery being finished with the employment of some force at 3.55. The bones separated 5 ctm. (2 inches). As the head emerged through the vulva a laceration occurred to the right of the urethra, so that there was an opening an inch long between the wound and the vagina, the labium minus remaining intact. Bleeding was moderate and easily checked by pressure with gauze and counter-pressure in the vagina. Peritoneum and bladder pouched sharply into the wound as soon as the bones gaped. The sutures were catgut and silk, and an attempt to steady the bones by including tissues close on the bone was found impracticable. No drain was used. Suturing was completed forty-five minutes after beginning the first incision. The operation was done at the King's County Hospital, with the assistance of my colleague, Dr. J. T. Duryea, and Drs. Thomson and Ambler, of the house staff.

The child was living, a male, weighing 7½ pounds (3,400 Gm.), 51.5 ctm. (20¼ inches) long, with a head measuring as follows: diameters, biparietal, 9.2 ctm. (3¾ inches); suboccipito-bregmatic, 10 ctm. (4 inches); occipito-frontal, 12 ctm. (4¾ inches); occipito-mental, 18½ ctm. (5¼ inches).

Adhesive strips and a tight binder were applied to the pelvis, and a long, moderately firm pillow was laid on each side of the bed, to make a trough in which the patient lay, bearing most of her weight on the trochanters and the iliac crests. On the third and ninth days her temperature rose to 101°, but calomel brought it down both times. Her recovery was otherwise uneventful, except for nervousness. She walked about the twenty-first day, our policy being to keep her long in bed.

At the end of seven and a half weeks her general condition was good, she walked perfectly, the wound had united without any deformity, and the motion in the joint amounted to an estimated quarter-inch (6 mm.) in an up and down direction when she was examined standing, swaying her weight from foot to foot, while the back and forward motion at such time was believed to be an eighth of an inch (3 mm.). The general contraction of the pelvis was verified and the pelvic contents found to be in normal condition, except that the rectum ran up on the right side of the promontory. The child was nursed by another patient and is doing fairly well.

The Trough-Bed.—By laying a long and moderately hard pillow along each side of the mattress, and placing the rubber sheet and other sheets above it, one may readily construct a trough or gutter in which a patient will lie in such fashion that the weight of the lower part of the trunk and of the thighs is taken on the iliac crests and the trochanters. The legs are thereby inrotated, the knees pressed together, and the tendency to separation

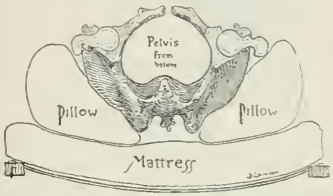

FIG. 1.—A trough formed by pillows holds the joint surfaces in contact during convalescence.

of the symphysis is overcome, as it occurs when the weight of the body is borne on the sacrum. In this way bed sores are less liable to occur, and there is a little room for the bed-pan to be slipped beneath the patient, while the inward pressure still continues. If the patient moves or tries to twist the body, the sloping sides of the trough, slippery on account of the rubber sheet over the pillows, keeps the pressure in the desired direction. In combination with adhesive plaster strips or a binder, this method gives us good approximation of the surfaces without expensive machinery, or apparatus requiring skilled care. The special girdles that have been devised and the plaster splints are rapidly soiled by the discharges. A binder requires constant tightening and, alone, is insufficient security. Even the use of adhesive strips has its drawbacks in action, because, if a strip is placed about the patient at the level of the trochanters, it prevents cleaning between the buttocks; whereas if it is placed about the iliac crests, it crosses the hypogastrium, where the pressure is liable to squeeze the bladder-wall or the peritoneum above the bladder into the joint, should the joint gape during the motions of the patient.

The Relations of the Peritoneum to the Joint.—What difficulty may arise from the pouching of the peritoneum into the wound, as it occurred in this case? A glance at the frozen sections of women who died late in pregnancy, and at various stages of labor, would lead us to expect to find the peritoneum in the way in certain cases. Braun[1] shows the peritoneum in late pregnancy dipping well below the symphysis, the head not being at all engaged in the cavity. See Fig. 3. Barbour and Webster[2] show the same condition, though the bladder is partly filled. The cervix is undilated and the breech sunk into the cavity. Winter's section before dilatation shows a two-inch dip of peritoneum. Barbour[3] gives Waldeyer's section of the ninth month, with the peritoneum close behind the symphysis. His own section, Fig. 5, at the beginning of labor, without dilatation, the head deep in the pelvis, gives the peritoneal dip low behind the bone, hugging it. In Schroeder's section, with beginning dilatation and the head well engaged, the peritoneum is close to the bone. In Chiari's case, also pictured, a transverse presentation with the arms delivered and good dilatation, the peritoneum is high above the symphysis, and the bladder drawn up beneath it.

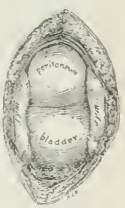

FIG. 2.—The bulging of peritoneum and bladder into the opening, in this case, after the bones separated.

[1] Atlas of Topographical Anatomy, Plate 29 B.
[2] Laboratory Reports, Royal College Physicians, Edin., vol. ii., Plate I.
[3] Anatomy of Labor, Atlas.

Barbour and Webster's section of the expulsion stage, Fig. 6, with the head at the vulva, shows the peritoneum drawn up nearly out of the way, the bladder lying in front of the peritoneum and guarding it from injury.

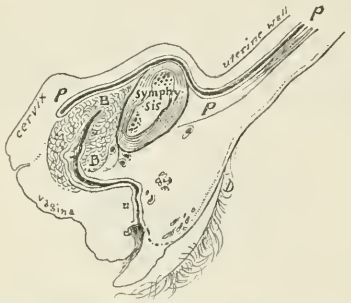

FIG. 3.—Sagittal section through the parts about the symphysis in the last month of pregnancy, where no dilatation or descent has occurred. B, bladder; p, p, p, peritoneum. The blood-vessels show well. Such conditions probably persist until dilatation is nearly completed. (Braun, one-third.)

In Braun's Plate 31, the head is also on the pelvic floor and the peritoneum is drawn up above it, Fig. 7. Webster [1] demonstrates that just after labor the peritoneum is found behind the bladder and the bladder behind the

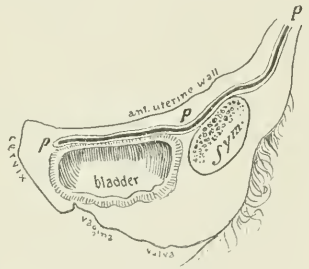

FIG. 4.—Section at eighth month with no dilatation, but breech sunk into the cavity. Even the partial filling of the bladder does not strip peritoneum off the joint. (Barbour, one-third.)

symphysis, but that in some cases the peritoneum lies directly on the posterior aspect of the symphysis, Fig. 8.

Thus we see that, as far as frozen sections go, the *peritoneum*, before full dilatation of the cervix, lies against the rear surface of the joint and the back of the bladder,

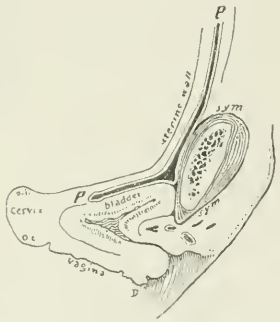

FIG. 5.—Beginning dilatation with head deep in pelvis; p, p, peritoneum, close to the bone. The vessels are also shown. (Barbour, one-third.)

but that after full canalization of the cervix, *together with* wedging of the presenting part well into the pelvis, the peritoneum is drawn upward with the anterior lip of the

[1] Researches in Pelvic Anatomy.

cervix and the bladder, so that it is entirely above the symphysis, is often stripped off the bladder, and is out of

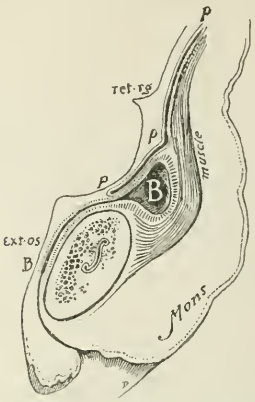

FIG. 6.—Expulsion stage, with complete dilatation and head on pelvic floor. Part of the bladder and peritoneum have been drawn up, and bladder and urethra are tightly applied to the symphysis. B, B, bladder; p, p, p, peritoneum. (Barbour, one-third.)

the way of any harm. After the uterus is emptied it is again found behind the symphysis.

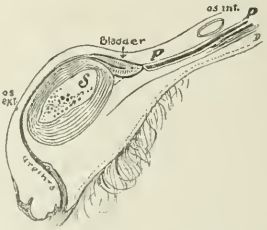

FIG. 7.—Obliteration of cervix with head at outlet of soft parts. Urethra and bladder are applied to hinder surface of symphysis, and the peritoneum is lifted and stripped off the bladder and the bone. S, symphysis, bone being dotted, and cartilage shaded. P, p, peritoneum. In cases where the operation is done for contracted outlet this and the previous figure show the conditions when the head is low. (Braun, one-third.)

In complete or nearly complete dilatation without descent, my case would go to show that the peritoneum

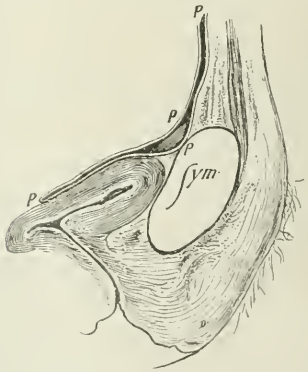

FIG. 8.—Condition five minutes after delivery. P, p, p, peritoneum. Peritoneum, bladder, and a little loose tissue are behind the symphysis. The relations are such as these while suturing is under way. (Webster, one-half.)

remains on the posterior aspect of the joint, with the bladder not drawn upward. This condition is not pictured in any of the charts.

During delivery, the *bladder* remains behind the pubes

strongly compressed against the bone, only the upper part being drawn up above it. This elevation does not occur until the second stage, and possibly not until the presenting part is driven into the pelvis. The *urethra* is not elongated during labor,[1] and its lower end does not materially alter its position; but the upper end is considerably elevated during the expulsion stage, and pressed hard against the symphysis.

The structures found behind the joint will be:

1. Before full dilatation and a certain degree of descent: Peritoneum and bladder (with little or no loose fatty tissue in the retro-pubic triangle, or cavum Retzii).

2. After full dilatation and some descent: Bladder (lower part) and urethra firmly pressed against the joint.

3. After delivery: Peritoneum, bladder, and a very little loose tissue.

The blood-vessels (veins) that are located behind the lower part of the symphysis in the retro pubic triangle in the imparous woman, will be found beneath the arch during labor (Figs. 3 and 5), and, with few exceptions, after delivery they are still nearly in the same position.

The amount of motion in the joint in this case, at the end of a few weeks, is not greater than is found in many hard labors and after many easy ones. To make sure of the facts in this matter, and to enable us to compare the results after symphyseotomy, after difficult or instrumental deliveries, and after ordinary labors, I am gathering data by means of the rubber stamp here given, which I print at the end of each of the history blanks of my two services. The words not needed are scored off.

CLINICAL EXPERIMENTS WITH CREOSOTE IN THE MANAGEMENT OF INOPERABLE CASES OF SURGICAL KIDNEY.

By LEONARD WEBER, M.D.,

NEW YORK.

Chronic pyelonephritis, caused by calculus or gonorrhœa or other infection, is a dangerous and destructive disease, to be sure, but not unfrequently amenable to proper surgical treatment by nephrotomy or nephrectomy. When a calculus occupies the pelvis of a kidney, reasonable assurance must be had that the other kidney is healthy, or nearly so, before the patient is subjected to a radical operation; when the trouble is bilateral there must be left sufficient renal tissue, both in extent and functional activity, to do the necessary secretory work, if an operation is to be undertaken. And further, the patient must not be too old and feeble, and comparatively free from other serious complications.

Other things being as they should be, it is finally the state of the patient's heart, both in considering the question of operation for surgical kidney, and in the prognosis of certain forms of chronic Bright's disease, that will safely guide us in deciding for or against operation or in stating a probable prognosis as to an early or remote fatal issue of renal disease. So long as the functional activity remains unimpaired in chronic diffuse nephritis, or the hypertrophied muscle of the left ventricle is equal to the compensatory work demanded of it in renal sclerosis, the patient will live without great distress and be even able to attend to his work. But how quick and sure comes a change for the worse when the compensatory hypertrophy is wanting, or, when present, gives place to atrophic dilatation or exhaustion from overwork? And similarly great is the danger from weak heart when a diseased kidney is to be removed; aside of the primary risk during anæsthesia, the patient's chances of recovery will be very small when there is functional insufficiency of the cardiac organ, though the state of the other kidney may be sufficiently good to warrant the operation.

Cases in which for good reasons no operation is advisable are not very rare, however, and the question how to relieve the patient's suffering, prolong his life, and perhaps improve his general condition, finally rests with the attending physician. He does the best he can with anodynes, alkaline mineral waters, baths, and the like, but it goes without saying that very little is accomplished in this way. During the management of the last four inoperable cases of surgical kidney with abundant discharge of pus and frequent paroxysms of fever, I observed that it was not so much by the loss of albumin and various more or less uræmic symptoms that the patient's life became endangered as by the septic condition produced by the suppurative process. Suppuration being once established by the action of the pyogenic microbes, as in calculous disease for instance, the discharge of pus with the urine will be more or less constant; indeed will flow steadily or come in gushes, but vary considerably in its daily quantity. Whenever temporary obstruction of a ureter occurred, as it was often noticed in Case II., given below, the discharge of pus being impeded by retention in a sinus, or by impaction of scaly detritus masses or calculous fragments in the ureter, acute symptoms of septic fever would set in, sometimes severely so, and, within a few weeks the patient be reduced to an alarming degree. And then the process of ulceration and destruction is advanced again through the cachectic condition brought about by the fever, inasmuch as the power of tissue-resistance is much diminished by it, and thus the disorder finally moves in a vicious circle.

In looking about for a remedy that might have good antiseptic properties and not only be safe to give, but could also be expected to act favorably upon the kidneys, as it is excreted by them to a large extent, it seemed to me best to try creosote. From 1888 to the present time I have prescribed the beech wood tar in more than one hundred and fifty cases of phthisis tuberculosa, and noticed that, in the far greater number of them it readily subdued the septic fever which is generally caused by the pyogenic virus complicating the tubercular infection, and which accompanies all well developed cases of tuberculosis. It was logical to expect similarly good results from its use in the septic fever of suppurative renal disease. My expectations were realized, and the palliative results have been so good that I may be justified, I hope, in drawing attention to the value of the drug in certain cases of suppurative nephritis. Others may be induced to give it a trial and help increase the number of observations. In the four cases I report on I have not found it necessary to give large and increasing doses, as I am in the habit of doing in tuberculosis, but have found that from three to five grains of creosote three times a day, in capsules, or in alcoholic solution by the mouth, or in the form of suppositories or injections by the rectum, will sufficiently impregnate the urine to correct its foul odor, reduce the fever, and improve the patient's general condition in a comparatively short space of time. There are some who deny to creosote any noteworthy therapeutic influence in phthisis; they are wrong, and so are those who extol it as a curative of almost specific influence. Though it does not visibly affect the bacillus tuberculosis it certainly does often assist the pulmonary tissue to regain the lost resistance to the baneful action of the bacillus tuberculosis. Pulmonary tissue infiltrated with tubercle is diseased tissue, so changed and paralyzed by the toxin of the bacillus that it falls a ready prey to destruction by the suppurative virus; that creosote is a sort of antidote of considerable power in overcoming the purulent infection I have good reason to believe.

The following is the history of four cases of surgical kidney in which creosote has been tried:

Case I.—L. M——, aged thirty-four, clerk; phthisical

[1] Webster: Researches in Pelvic Anatomy, p. 98.

taint in his family; had small glandular abscesses in early life, frequently naso-bronchial catarrh, never hæmoptœ. In fairly good health and vigor at twenty; severe and protracted gonorrhœa at twenty-four, followed by bilateral pyelitis ushered in by severe chill and fever; has had bad health ever since, though able to attend to business most of the time. Urine never free from pus; blood and renal epithelia frequently to be found in sediment. Calculus or tubercle probably not present. By none of the various methods applied has he derived any benefit comparable to the relief obtained by creosote which he has taken now for a year. Has not had febrile temperatures for many months, gained in weight, looks and feels better, urine clearer, micturition less frequent.

Case II.—L. B——, aged sixty-eight, a merchant, originally of sound and vigorous constitution, though troubled with chronic bronchial catarrh for more than forty years, to which has been added some emphysema of late years. First symptoms of renal trouble on the right side about twelve years ago, associated with pain in region of kidney and hæmaturia; probably calculus. The disease progressed gradually, his health became poor during the last two years, and the urine contained pus, sometimes in considerable quantities. The right kidney is now enlarged, as can be readily demonstrated by bimanual examination. Left kidney very probably also diseased, for his urine is of constant low specific gravity, and the diuresis much increased, and steadily so for the last five years. Heart still comparatively strong, the complication of disorders notwithstanding. In the summer of 1892 sudden attack of retention of urine, right side, through the temporary blocking of ureter by soft, scaly, fibrinous detritus masses, showing no tissue-formation under the microscope. Sharp pain, chills and fever followed by abundant discharge of urine and pus after the obstructing masses had been forced out by pressure *a tergo*. Until the end of 1892 patient had five or six repetitions of such attacks by which he was greatly reduced in health and strength, losing about thirty pounds in weight. Drs. Lange and Keyes of this city saw the patient with me, and we were all agreed that his general condition did not warrant the undertaking of an operation. For nearly ten months Mr. B. has now been taking creosote, two to four grains three times daily. Last winter he spent three months down South, and has not had a recurrence of his attacks since March last. General health considerably improved, urine contains much less pus than before.

Case III.—E. S——, aged fifty-four, a tradesman; no hereditary nor acquired taint; fairly strong, though very nervous man; pulse good enough; heart's action irregular, but no false sounds. First seen by me about ten years ago for abscess of the appendix vermiformis. Had been ill at that time with all the symptoms of appendicitis, his attending physician said, for three weeks. We found that the abscess had already perforated the bladder, and in the fourth week also burst into the rectum, and finally healed up perfectly, in that way leaving the man as well as he ever remembered to have been in his life. During the last two years he has some of the symptoms of renal calculus on right side, and of late pus in urine and sometimes fever. Has taken creosote now for three months, and been benefited in the same way as the foregoing case.

Case IV.—Mrs. S. S——, aged seventy two, stout, somewhat anæmic woman. For the last ten years symptoms of renal disorder and chronic bronchial catarrh; urine now contains much pus, also some blood. Rigors and febrile temperatures from time to time and general failing in health. That she has chronic suppurative nephritis is beyond a doubt; but as the patient lives away out in the country, and I have not had occasion to see her more than twice, I can say nothing as to the underlying cause, but from reports made to me I may state that she has taken creosote now for three months, and is said to be free of fever and in generally improved condition.

A PLEA FOR THE EARLY DIAGNOSIS AND PROMPT ELECTRICAL TREATMENT OF FIBROID GROWTHS OF THE UTERUS.[1]

By G. BETTON MASSEY, M.D.,

PHILADELPHIA, PA.

The questions briefly considered in this paper are: the nature and symptoms of the early manifestations of uterine fibrosis and myomatous new growths; the duties of the profession in making a prompt diagnosis and instituting early treatment for the condition; and a consideration of the value of the Apostoli methods in these cases.

The etiology of fibroid growths within the uterine parenchyma is still obscure, but enough is known of fibrosis in general to show that it is an hypertrophy of the connective tissue elements, or in the case of myomas, of the uterine parenchyma itself. According to the classification laid down by Loomis in his discussion on Fibroid Processes, at the Congress of American Physicians and Surgeons at Washington, in 1891, the process under consideration is probably somewhat distinct from that found in ordinary inflammation, though allied to it, and is dependent on a perversion of the nutritive supply, which is insufficient to maintain the higher elements, the connective-tissue cells, which maintain a lower nutrition, going on to hyperplasia. According to this definition the disease is essentially an affection of the local trophic processes.

Arising in a disordered condition of the trophic nerves of the uterus, uterine fibrosis may either be found associated with chronic interstitial metritis, or else simulating this affection by the production of similar symptoms in the early stages of the growth of the buds. Interstitial fibrosis, in fact, is not clearly distinguishable from the later stages of chronic metritis, at least clinically, and under the designation of hyperplasia may be considered as one of the conditions to which this paper invites the early attention of physicians. The brawny, cartilaginous, enlarged organ becomes almost a foreign body within the pelvis. There may be lacerations of the cervix remaining also as evidence of the causative conditions, but the disease now present cannot be cured by their repair. Such efforts are too much like locking the stable door after the horse is stolen. A more healthy tone must be imparted to the depressed trophic nerves of the organ, in order that the normal histological elements may be stimulated into renewed life.

Cases in which the fibroid growth is in the shape of isolated foci of development surrounded by normal uterine tissue, are more important, as it is this form that results in the progressively increasing neoplasms that at times attain enormous proportions and give rise to much suffering. Beginning as small nodules in various portions of the uterine wall, the greater number of these cases present symptoms in their earliest stages that should attract the attention of the physician, but too often they are mistaken for ulceration, metritis, displacements, and even ovarian disease. Cases are at times supposed to be suffering from oöphoritis or salpingitis, when the trouble is really a fibroid bud springing from the side of the uterus in the region of the broad ligament. The diagnostic aid to be derived from a supposed locating of a tender spot is extremely unreliable. Many a tender ovary may be cured by treatment directed to the uterus, and *vice versa*.

I have repeatedly called attention of late to these interchangeable evidences of uterine treatment and oöphoritis, showing that many so called cases of ovarian disease were really instances of catarrhal and interstitial metritis, and it has been while pursuing the treatment of some of these by the intra-uterine method, that still further revelations have been made. An enlarged uterus, which has given rise to symptoms that have been referred to the ovaries by surgical friends, with the natural consequences as to advice on their part, on being placed under the

[1] Read before the Section of Gynecology and Abdominal Surgery of the Pan-American Medical Congress, Washington, D. C., September 6, 1893

intra-uterine galvanic treatment would shortly present a shrinkage everywhere but at one point. Here a nodule could now be detected which had been concealed before by the general uterine hyperplasia. Under a continuance of the same treatment I have several times had the satisfaction of seeing the lump grow smaller, coincident with a disappearance of the symptoms, demonstrating that I had not only stumbled upon an incipient fibroid growth of the organ, but had also relieved the patient from a most unpleasant future.

About seventy-five per cent. of my cases gave a history of having been treated for some form of womb disease for varying periods, before the recognition of the tumor. It is safe to say that nearly all of these had nodules present throughout their trying experiences with tampons and pessaries; and had a proper diagnosis been made, could have been saved years of subsequent suffering. Early recognition and early treatment would have secured relief at a time when it is most easily given. Moreover, the early treatment of fibroid growths has the advantage of placing all cases within the list of those amenable to electricity, while delay permits of some becoming unsuitable for it by reason of cystic or other degenerative changes, which appear only after considerable size has been attained.

The too prevalent attitude of expectancy on the part of the profession is well illustrated by the cases of physicians' wives with tumors, who have been under my care: about five per cent. of the whole number of cases treated. The tumor in each one of these cases was as large or larger than the adult head.

The discovery that painful periods, or particularly that intermenstrual pain, weight, and discomfort, are associated with an enlargement of the uterus, should lead to a more thorough investigation of the case to determine the presence or absence of fibroids. Now that an almost certain relief may be obtained from electric treatment, there is no longer any excuse for a waiting policy, that not only prolongs the discomfort of the patient, but renders treatment, when finally undertaken, both more tedious and more difficult.

212 South Fifteenth Street.

THE ORIGIN OF THE NON-RESTRAINT SYSTEM IN THE TREATMENT OF THE INSANE.

By WILLIAM PHILIP SPRATLING, M.D.,

NEW YORK.

Late First Assistant Physician to New Jersey State Hospital for the Insane at Morris Plains; Member of New York County Medical Society, and of the Harlem Medical Association of the City of New York.

So much has been said and written about the non-restraint system in the treatment of the insane during the past decade, that it seems unnecessary to call the attention of the profession to the subject again. I do not desire to awaken, or reopen, a discussion of the merits of the system; and what I have here to state will be of more interest to the historian than to the practical alienist and custodian of that great class of unfortunates.

In June, 1891, while visiting some of the hospitals for the insane in England, and on the continent, I had a lengthy and delightful conversation with Dr. G. Fielding Blandford, the eminent English alienist, on the subject. In the course of our conversation I referred to non-restraint as "Connollyism," a term regarded as synonymous with non-restraint by most of the asylum superintendents in this country. Dr. Connolly is supposed to have inaugurated the non-restraint system during his term of service as Superintendent of Hanwell Asylum, which began in 1838. Dr. Blandford at once told me that Connolly did not originate the system, and that all credit for its origin was due to Dr. Gardiner Hill and Dr. Charlesworth of the Lincoln Asylum, an institution smaller than Hanwell, and more remote from London.

After my return to New York I wrote Dr. Blandford for the facts above stated, with his permission to make them public. This is his letter:

"48 Wimpole Street, London, England.

"My Dear Sir: It is quite true that Dr. Connolly did not inaugurate the non-restraint system. It commenced at the Lincoln Asylum, and to Dr. Gardiner Hill and Dr. Charlesworth is due the credit of having initiated it. Dr. Connolly, in his first report, presented Michaelmas, 1839, and now before me, says: 'The example of the Lincoln Asylum, in which no patient has been put in restraint for nearly three years, comes powerfully in aid of an attempt to govern the asylum at Hanwell by mental restraint rather than by physical.' He goes on to say that the daily number in restraint at Hanwell was, in July, so reduced that there were sometimes only four, and never more than fourteen, in restraint at one time; but that since the middle of August there has not been one patient in restraint on the female side of the house, and since the 21st of September not one on either side.

"Clearly, Dr. Connolly, following the example at Lincoln, gradually did away with restraint at Hanwell. The latter being a very large asylum and close to London, brought the system into notice. Lincoln was forgotten, and Connolly got all the glory.

"I remain truly yours,

"G. Fielding Blandford."

January 2, 1892.

The evidence that Dr. Blandford here presents to show that Connolly did not inaugurate the non restraint system is far-reaching and effective. Let me again call attention to that part of his letter where he quotes from Dr. Connolly's report, and in which Dr. Connolly is made to say: "The example of the Lincoln Asylum, in which no patient has been put in restraint for nearly three years, comes powerfully in aid of an attempt to govern the asylum at Hanwell by mental restraint rather than by physical." After having written so much of this paper, Dr. B. D. Evans, Medical Director of the New Jersey State Hospital at Morris Plains, called my attention to the fact that Dr. Hack Tuke, in his "Dictionary of Psychological Medicine," verifies Dr. Blandford's statements as to the origin of the non-restraint system. In vol. i., page 25, Dr. Tuke says: "Gardiner Hill and Charlesworth introduced, at the Lincoln Asylum, the system known as non-restraint. It was a gradual work, culminating in the formal abolition of restraint in 1837. Every friend of the insane should feel thankful to these men for the humane course they pursued, and the attention they drew to the evil of the excessive resort to mechanical restraint, then, too frequently practised, in spite of the great advance which had been made in the management of the British asylums. To Dr Connolly, who became the ardent apostle of this system, we ought to pay the homage to which his labors so justly entitle him. He, in the height of his fame, generously accorded the meed of praise to those who had preceded him at the New York Retreat and at Lincoln, and had paved the way to his extended field of labor at the Hanwell Asylum, where his memory should ever be cherished with gratitude and affection."

Each decade that passes by will serve to enhance the value of Gardiner Hill's and Charlesworth's new departure in the treatment of the insane to mankind. The time is not yet ripe when the full meed of praise and honor, that they so richly deserve, can be given them. A century hence the glory will be theirs.

70 West Eighty-eighth Street, November 7, 1893.

The Medical Society of New Jersey claims to be the oldest State Medical Society in the United States, and among the first to secure an act from its Colonial Assembly to legalize and regulate the practice of medicine. The first State law regulating medical practice in New Jersey was passed in 1783. So says Dr. E. L. B. Godfrey, of Camden, N. J.

Clinical Department.

ODONTALGIA, EMERGENCY TREATMENT (A CRITICISM).

By CHARLES G. PEASE, M.D., D.D.S.,
NEW YORK

I AM led to write upon this subject, having read the article, "The Emergency Treatment of a Toothache," appearing in the MEDICAL RECORD of the issue of November 11, 1893, and will here discuss the same for the benefit of the writer of that article and the profession in general. In the first place the essayist states that "the treatment for an aching tooth causing inflammation of the jaw and gums with swelling, is the insertion of a medicated pellet of cotton into the cavity of the tooth, if there be one." Now, my comment upon this line of treatment is that it should be just the reverse, for the reason that with these conditions we have, without doubt, a devitalized tooth to deal with, and if so, the cotton should not only not be put in but the cavity should be freely opened and the pulp-chamber and pulp-canals, which formerly held the living pulp, thoroughly vented, to allow the escape of gas and venting of pus, if any has formed, external to the apical foramen. The gums could be painted with iodine to stimulate the lymphatics in carrying away the products of inflammation. Immediate relief will accompany the proper venting of the canal or canals.

Where pain is the result of pulp irritation dependent on caries, we will find no external swelling as a result of said irritation, and here we are to use the medicated cotton, placing the pellet in the cavity; but before doing so it is necessary for the obtaining of the desired results to free the cavity of the débris that the medicament may come in contact with the dentine or pulp, if it be exposed. The cavity should be syringed out with warm water of an alkaline reaction, that it may neutralize the acid condition of the cavity, concomitant with decomposition, and relieve the pulp of this source of irritation. The cavity is then dried. Too much pressure should not be exerted in placing the cotton when the pulp is exposed, or when the dentine over the same is very thin and easily depressed. A retaining pellet should also be used, dipped in a solution of gum sandrac and alcohol.

I would also criticize the treatment, recommended in the article I am discussing, of swollen and tender gums, *i.e.*, with doses of subcarbonate of bismuth, phenacetine, laxatives, etc. I claim this dosing of the patient is wholly unnecessary, and would refer to my article on "Pyorrhœa Alveolaris often Diagnosed as Facial Neuralgia," which appeared in the MEDICAL RECORD of February 13, 1892; swollen and tender gums most frequently resulting from the conditions described therein. Bicarbonate of soda is most valuable as a mouth wash, especially before retiring, and by all means during pregnancy, as a prophylaxis.

101 WEST SEVENTY-SECOND STREET.

A CASE OF APHONIA DUE TO HYPERTROPHIC RHINITIS.

By HOWARD S. STRAIGHT, M.D.,
CLEVELAND, O.

IN May, 1889, O. S——, a boy of German parentage, seventeen years of age, came to the John Huntington Dispensary. He had not been able to speak aloud for two years. He could whisper, but even his ability to whisper distinctly varied at times. He was a healthy, well-developed young man, and had never had any serious illness. He said that about three years before he had lost his voice for six months. This period was followed by two months, during which time he again had the use of his voice. He was a grocery clerk, and caught cold one evening when washing windows. He was sick for a week and must have had follicular tonsillitis. With the onset of this cold he again became aphonic, and this condition continued until he came under my observation. He had had catarrh in his head for some years, but it had troubled him more for the last three years than before that time. He also said that he had noticed that whenever he caught cold in his head he could not whisper so well. His laryngoscopic examination showed nothing abnormal. There was no disease of the pharynx, naso pharynx, or tonsils. He had, however, a well marked hypertrophic rhinitis. The hypertrophy was limited to the anterior and posterior turbinated bones. The middle turbinated were normal. Whether the nasal condition could account for his aphonia was a question, but in the absence of any other abnormal condition of the upper air-passages, it seemed wise to treat the nasal hypertrophy.

May 16, 1889, his right anterior turbinated hypertrophy was thoroughly reduced by means of the galvanocautery. Four days later his left anterior turbinated was subjected to the same treatment. May 24th—eight days after the first cauterization—he returned. There was no change in his condition. At this time I cauterized his right posterior turbinated. That same evening one of his companions punched him, and he attempted to whisper "Oh," when to his very great surprise he said it aloud. He now found he could speak, and returned the next day to show me the change in his condition. He could speak again, but the control of his larynx was so imperfect that his talking sounded much like the crowing of a young rooster. This inability to speak in the same tone soon passed away, and after the treatment of his nose was finished he returned to his home.

August 25, 1893, he again visited me. He stated that he had had no trouble with his voice or nose since the completion of his treatment—a period of four years. The greatest sceptic as to the occurrence of neuroses due to diseased nasal conditions would, it seems to me, find difficulty in explaining this case upon any other basis. Cases of aphonia due to nasal catarrh, and which were cured by treatment directed to this organ, have been reported within the last few years. The thickening of the mucous membrane over the posterior turbinated was in this case very marked. The posterior nares were almost completely filled up.

The aphonia must have been due to the pressure of this hypertrophy. The cauterization of the anterior turbinated had produced no change is his condition. The same treatment applied to his right posterior turbinated, produced an immediate correction of his aphonia, for he spoke within twelve hours after cauterization. This result was also attained before the left posterior turbinated had received any treatment whatever—as soon, in fact, as the pressure upon the posterior portion of the septum was partially relieved.

Three factors are necessary for an explanation of reflex action: an afferent nerve, a nerve-centre or a transferring centre, and an efferent nerve. These three factors in the case reported are as follows: Meckel's ganglion or the spheno palatine ganglion, one of the cephalic ganglia of the sympathetic, sends sensory branches to the posterior part of the septum and to the posterior turbinated bones. These branches—some one of them—supply the afferent nerve, and the pressure upon them furnishes the first link in the reflex mechanism. The connection of the spheno-palatine ganglion with the sympathetic and the pneumogastric, and other of the ganglia of the sympathetic, is well known.

The efferent nerve in this case was certainly the recurrent laryngeal; which ganglion acted as the transferring centre cannot be decided. Why the sensory effect should have been transferred to the recurrent laryngeal rather than to some other branch of the pneumogastric, is equally impossible of explanation. If the sensory impression had chosen the œsophageal branches he might have had difficulty in swallowing; or the superior laryn-

geal, he would have had a throat cough, or the cardiac branches, he would have suffered from disordered heart-action; or the pulmonary branches, he would have had disturbance of respiration. This seems to me to be a perfectly logical conclusion.

Cases of asthma, of difficulty of swallowing, of disordered heart-action due to nasal disease, have been reported; and why this case should have suffered from aphonia and not from some other neurosis, I know no reason. Cases of this kind have been reported by competent observers since Voltileni called attention to them in 1871.

From the earliest days of medicine it has been believed that various neuroses could be produced by disease of the nose. Hack, who was a very great enthusiast, did more than any other observer to direct attention to their occurrence. The attitude of the profession as regards nasal neuroses, has been either one of extreme scepticism or exaggerated belief, while it is possible that the rhinologist may have erred in ascribing undue importance to the local condition, it is equally possible that the general practitioner may not have given the subject proper consideration. It has been claimed that spurs upon the septum can cause aural tinnitus, that certain headaches are dependent upon disease of the nose, and that epilepsy, vertigo, and even neurasthenia may owe their origin to the same cause. McBride, of Edinburgh reports a case of first attack of epilepsy during the passage of an Eustachian catheter. It is claimed that even vaso motor disturbances in the nasal mucous membrane without thickening, can give rise to the various neuroses mentioned.

That nasal neuroses may occur the case reported proves, it seems to me, and yet in a special practice of six years I have seen only one other case—this case being one of a burning sensation starting in the nose, and spreading to the hands and feet. I have been attempting for years to find cases of asthma that would be benefited by removal of polypi or a correction of an abnormal nasal condition. I believe such cases can occur, but I have yet to see such a case, although I was chief of the throat and chest department of the John Huntington Dispensary for five years. Such cases must be rare.

My attention was early directed to the possibility of neuroses arising from nasal disease. In the beginning I was a sceptic, and while this case, I confess, made a great impression upon me, my scepticism still continues. While I believe their occurrence possible, while I have been on the lookout for them, I have more often found the explanation of difficulty of swallowing, disordered heart-action, etc., in the patient's general condition.

There seems to be a tendency to overestimate the local condition by the rhinologist; there seems to be a good reason for believing that the fault may be with the nerve centre—the transferring cell—that receives the sensory impression. If this cell is irritable and depressed, if, in other words, the constitutional condition of the patient is below par, why is it not a reasonable inference that a normal afferent stimulation might produce an exaggerated effect upon this unstable cell?

If the rhinologist thinks the local condition to be the etiological factor, and treats the nasal area to which the terminal branches of the nerve-centres are distributed and the neurosis is relieved, why can we not explain the result by the effects of the counter-irritation upon the central cell?

Counter-irritation certainly produces trophic influences upon remote parts by sensory impressions. This is an every-day observation. Why should this fact not apply to the nasal mucous membrane as well as to any other portion of the body?

If an abnormal condition of the nose exists, it ought to be corrected, of course, and the possibility of nasal disease being accountable for certain neuroses in a small number of cases, ought never to be lost sight of, and yet the physician who studies the general condition of his patient more than the local will be making an error, if error at all, upon the right side.

GONORRHŒA IN CHILDREN.

By ADOLPH A. HIMOWICH, M.D.,

NEW YORK.

Gonorrhœa in children is considered a very rare occurrence. Most of our best text-books on diseases of children have no mention of it. Some have merely a passing remark on specific vulvitis. For instance, Professor Eustace Smith remarks that cases of specific vaginitis may sometimes occur, but they are very rare.

In W. H. Day's "Diseases of Children" a clear description of purulent vaginitis is given, stating that the disease is obstinate in character in spite of cleanliness and most careful treatment, but ascribes its origin to weakness of constitution and strumous habits.

In the last edition of Ashby and Wright, after ascribing the cause of vulvitis to neglect and dirt, and often to irritation of thread-worms, we find the following remark: "Very rarely indeed is it the result of attempted rape, and such charges are often brought against innocent persons." Quite a different view on the subject is taken by Professor E. Henoch. In his lecture on purulent vaginitis we find the following statement: "In such cases one is apt to suspect that there has been an attempt of assault, and I know from my own experience that the suspicion is sometimes only too well founded. I have notes of a whole series of cases of children between four to eleven years of age, falling victims to brutality, indecency, or a certain superstition in some of them. In some of them there had been an actual attempt at rape, or there might have been indecent manipulation."

In my practice in a thickly populated tenement district, I have met a considerable number of cases of vulvo-vaginitis. Some of them have been under treatment for quite a long time as "simple" vaginitis; but not yielding to treatment, the parents thought it advisable to consult another physician. In one of these cases, L. W——, a girl about three years of age, I was able to trace the origin of the disease to direct infection. A boarder in the house, who was suspected, confessed that he infected the child by direct contact.

Another case, R. H——, a girl about four years of age, was also suffering very long from a purulent discharge from the vagina. The mother suspected her child to have been the victim of indecent manipulation, but no confession could be secured from the suspected person. The character and persistence of the discharge, the pain during micturition, and swelling of the vulva, were sufficient evidence that the mother's suspicion was well founded.

On June 4, 1893, Mrs. S. A—— brought to my office her infant, E. A——, aged two, who was suffering from a purulent discharge from the vagina. The labia and mucous membrane were red and swollen. Suspecting strongly it to be a case of specific vulvo vaginitis, I began to question the mother whether she was suffering from a similar discharge. She assured me that she was not, and was ready to prove it by an examination. She was equally sure that her husband was free from any such disease. Further inquiry, however, revealed the fact that a young man, a relative of hers, living in her house, was taking medicine for a long time. He was very fond of the infant and very frequently had her in his bed. It was ascertained that the young man was suffering from gonorrhœa. I took the child to Dr. W. L. Stowell's clinic, at the University Medical College. The discharge was examined by Dr. F. Abbot, Jr., and quite a number of gonococci was found.

Soon after a brother of the baby, aged six, was brought to my office with the same disease. There was a copious purulent discharge from the penis, pain on micturition, and all the symptoms of a severe gonorrhœa. The mother, being alarmed, asked me to put the boy in a hospital. Accordingly, I sent him to St. John's Guild Hospital, where he remained for several weeks and was discharged not much improved.

While he was in the hospital a brother of his, aged

eight, had a mild attack of gonorrhœa. He was suffering from a constant sticking pain at the meatus urinaris, which pain was much aggravated during micturition. On squeezing the penis a few drops of pus was passed out. Both boys were sent to the City Hospital. They remained there a few weeks and were discharged in very much the same condition as admitted. The infant, aged two, recovered completely. The eight years' old boy is improved, while his younger brother is still suffering from a purulent discharge and pain. Is it gleet?

The cases reported here seem to me to be interesting and instructive in many ways. It is quite probable that specific vulvo-vaginitis is not so rare as it is generally supposed to be, and it is very important that the attention of the profession be called to this evil. Many cases of so-called simple vaginitis are in reality specific in their nature, and would prove so if frequent microscopic examination of the discharge be made.

Although the majority of the text books claim an innocent nature of the discharge in obstinate cases of vulvo-vaginitis, I am inclined to believe with Professor Henoch, that many of these cases are due to indecent manipulation by persons suffering from gonorrhœa. In some of them there may have been an actual attempt at rape.

Is it not possible that the well-recognized infectious nature of simple (?) vaginitis may be due to the fact that it is not so simple after all?

Progress of Medical Science.

Arthrodesis. — Dr. Roersch, of Liége, has recently called attention to a special application of resection of the knee to which little attention has been paid, and which, even when the recognized indications for this operation were more numerous than at the present day, was seldom noticed in text-books on surgery. In most of these books it will be found that the list of such indications deals exclusively with instances either of some morbid condition limited to the joint or of crippling of the limb from previous articular injury or disease. Of late the tendency with most surgeons has been to diminish the range of resection, especially with regard to the knee, and to very few must the idea have occurred that removal of this joint while in a sound condition might prove indirectly beneficial for the relief of the results of non-articular disease. We are reminded, however, that in 1878 Albert, of Vienna, resected both knees, which were structurally normal, of a girl affected with essential paralysis of the lower limbs, with the object of establishing anchylosis and of converting the atrophied and yielding members into two firm columns of support. To articular resection performed with this aim the title of arthrodesis has been given. Albert's example has been followed by Von Winiwarter and several German surgeons, and his innovating orthopædic method has recently met with firm supporters in France. Roersch, in his review on the history of arthrodesis, omits to mention that the method has been tried in this country also, and practised in cases of paralysis of the lower limbs by Mr. Wright, of Manchester, and by Mr. Jacobson, of Guy's Hospital.

While Albert and most of his followers would regard arthrodesis as the suppression of a healthy joint with the object of rendering a paralyzed limb firm and solid, Roersch would apply the term to the establishing of anchylosis in a diseased as well as in a sound joint. A resection of any weak and loose joint would thus be regarded as an instance of arthrodesis, and the method thus called would have included in its list of indications arthritis deformans and tabetic and other neuropathic affections of joints. Roersch would extend the list still further, and regard secondary resection for failure of anchylosis after removal of a diseased joint as a measure of arthrodesis. He would add also resection of the extremity of the bone in cases of congenital and other forms of luxation in which reduction cannot be maintained. Still further indications are found in old and aggravated club-foot and in paralytic talipes. This extended application of the term cannot fail to cause much confusion, and it would be better to restrict it to its original meaning, so as to imply by its use the operative suppression of a very loose but otherwise healthy joint in cases of infantile and other forms of persistent muscular paralysis.

The knee, although it presents the most favorable conditions for the establishing of osseous anchylosis, is not the only joint on which arthrodesis has been performed. Both the ankle and hip joints have been resected in cases of paralytic affections of the lower extremity, the former perhaps more frequently than any other joint, the latter but seldom. In the upper limb indications for arthrodesis do not often occur. By abolishing the movements at the shoulder, much weight may be taken off the muscles of a paralyzed arm, and such movements as can still be performed at the elbow are rendered less difficult. These objects, however, may be attained more effectually by the use of an artificial support, particularly as resection of the shoulder is unlikely to result in osseous anchylosis. Arthrodesis has in some few instances been practised at the elbow, and in one case of infantile paralysis of the upper extremity von Winiwater excised the wrist. In arthrodesis for paralytic weakness of the lower limbs it is usually found necessary, in order to afford sufficient support, to operate on more than one joint. Wright removed both knee and ankle of the same limb. Von Winiwater also removed both these joints in two cases. In one case this surgeon operated on both knees at the same time, and in another removal of both knees was followed, after an interval of a month, by removal of both ankles. Döllinger has recently operated with success on the three principal joints of the same lower extremity. In the opinions of most surgeons the joint to be first attacked is the knee.

Of the forms of muscular paralysis of the limbs, which by their effects on the joints may indicate arthrodesis, those which seem most favorable to the operation are such as are due to anterior poliomyelitis. Certainly we may regard as suitable for this treatment many cases of infantile paralysis in which the joints of the affected limb are either very loose or fixed in an abnormal position by muscular contracture. Such conditions, as Roersch points out, condemn the patient to a state of almost absolute disability for the rest of life, while the general health often leaves nothing to be desired. Albert has operated in cases of paralysis following enteric fever and variola. Incurable muscular paralysis caused by ununited section of one or more nerves, and also paralysis due to neuritis, are further indications of arthrodesis. This treatment has been recommended also in cases of progressive muscular atrophy.

With regard to the results of this heroic treatment, which must necessarily be practised on those who would seem to be unfavorable subjects for any kind of surgical intervention, a most striking fact is the freedom of the operations from any serious risk. Of the ten cases treated by Von Winiwater, which are reported in Roersch's paper, not one had an immediate fatal result, and no mention of such misfortune is to be found in any of the numerous cases that have been recorded by other surgeons. Such results are remarkable, as *opérations de complaisance*, of which arthrodesis may be taken as a good example, are, as is generally believed, peculiarly subject to risk. We need, however, definite information as to the later results of this treatment, and the amount of benefit to be derived from it. Jacobson and Wright have obtained good results, but hitherto, we believe, very few cases have been recorded in this country. In France arthrodesis has found several warm supporters, and Roersch, one of the most zealous of these, asserts that it has been attended with much success. The results obtained by Von Winiwater in most of his cases of infantile paralysis seem to have been very favorable, several patients being able after resection of two or more joints to move about without crutches or any artificial supports

to the paralyzed limbs. Death occurred after long intervals in two cases, in one from injury, in the other from diphtheria, but there is no record of any failure. Petersen, who excised the knees in two cases of infantile paralysis, states that his patients were delighted with the results. On the other hand, Wolff is disposed to commisserate the subjects of these multiple operations, and to regard their future lot as being far from enviable.—*The British Medical Journal.*

Effects of the Influenza Poison on the Lying-in Woman.—At a recent meeting of the Obstetrical Society of London (*The Lancet*) a paper was communicated by Dr. Addinsell on the "Effects of the Influenza Poison upon the Lying in Woman." He described several cases which had been under his care, and showed how they differed from puerperal septicæmia. He also cited the case of a patient who suffered from dengue in her confinement, and its effects on the lochia and milk, pointing out the strong resemblance between this disease and influenza. He considered that influenza attacked the weakest spot, quoting instances of several patients seized with the disease at the time of menstruation who suffered, and still suffered, from ovaritis traceable to that time, and he finally suggested that the nervous symptoms so often seen in puerperal septicæmia, and which were very marked in the most severe of his series of cases, might be due to the necrotic elements of the endometrium not being carried off in the usual lochial discharge, and thus being absorbed and carried into the cerebral circulation. The President said that he had seen two cases of febrile illness, one consisting of repeated febrile attacks following delivery, the other of a febrile attack interrupting recovery after the opening of a pelvic abscess, and he had concurred with the physicians in attendance in ascribing those cases to influenza, rather because no other cause was found than because there was anything distinctive in the illness.

Treatment of Fracture of the Femur in the New-born.—Dr. Ellefson has recently had opportunity to try a method of treatment of this form of fracture which he found recommended by Bouchut. Fracture of the femur in the new born is accompanied by difficulties which can only partly be overcome. The various kinds of bandages which have been employed are nearly impossible to keep clean and dry; frequent changing interferes with healing. At a breech presentation where the midwife was so unfortunate as to break the femur at about an inch from the hip joint, he was called to dress the fracture. Two splints were applied, covered with flannel and corresponding with the anterior and posterior surfaces of the femur; then cotton wadding, and around the whole a circular bandage. The thigh was fixed in extreme flexion upon the child's abdomen by a few turns of the bandage. A little cushion is placed between the child's leg and thigh. The few turns of circular bandage will naturally become wet through, but they can be changed easily without disturbing the fracture. After fifteen days the bandage was removed and the fracture was found to have healed without shortening or disfiguration of the thigh. The forced flexion of the thigh and fixation to the abdomen did not seem to have disturbed the infant, which was perfectly well during the whole time.—*Annals of Surgery.*

Resection of the Rectum with Transverse Separation of the Sacrum.—Dr. Levy proposed, more than three years ago, a method of resection of the rectum, the prominent features of which included the proposition, 1, to leave intact the lower or external anal sphincter; 2, to preserve the coccyx; 3, to avoid injury to the levator ani. He has more recently modified his procedure as follows: An arch-shaped incision is made through the skin and fascia, over the lower end of the sacrum. This is located a finger's breadth above the points of the cornua of the coccyx. Laterally it is continued upon either side to a point five centimetres from the tuberosity of the ischium, and parallel to the course of the fibres of the gluteus maximus. Below the fourth sacral foramen the incision is carried to the bone, the lateral muscular fibres are separated by a blunt dissection until the lateral edges of the greater sacro-sciatic ligament are reached. This is carefully divided upon a grooved director. A chain-saw is now introduced in front of the sacrum, a special elevator being used to separate the soft parts upon its anterior surface; the chain saw is passed between these and the bone. The flap of bone and skin is now drawn downward, the coccygeus and sacro-sciatic ligaments being still further divided, if necessary. The pudendo-hemorrhoidal and the fourth sacral nerves are not injured by this procedure. In case an insufficient amount of space is afforded, the osteo plastic flap may be divided longitudinally.—*Annals of Surgery.*

Treatment of the Pyodermites.—Professor Leloir, in an article on this variety of skin diseases, in which he lays particular stress on the infective origin of the diseases, concludes with the following suggestions on treatment. He says: The treatment should have a double object in view. 1, We must sterilize the pyodermites; 2, we must prevent secondary auto-inoculations by the fingers, clothes, etc., of the patient. The treatment can be carried out in the following manner: Sterilization by antiseptic substances. Isolation by occlusive dressings. Added to these, therapeutic or medicinal remedies in accordance with general indications. For the superficial pyodermites, such as ecthyma, impetigo, etc., he employs ointments of boric or salicylic acids, salol dermatol, and more rarely of iodoform and perchloride. These pastes and ointments are applied on lint or gauze. The more deeply seated pyodermites, such as boils, anthrax, etc., he treats with the following paste:

Hydrargyri	parts 20
Terebenthini	" 20
Emp. plumbi	" 50
Resinæ	" 10
Acid. carbolic	" 7
Extract. belladon	" 10

This is spread on linen to the thickness of a silver dollar, and applied so that it extends beyond the affected area about one and a half inch. It should be covered with gutta-percha and a thick pad of lint, and then bandaged. This dressing is left on for twelve or sometimes twenty-four hours. In cases of anthrax, before each, dressing the part affected should be sprayed with carbolic acid diluted, the skin should then be cleaned with a tampon soaked in iodoform ether, or in certain cases with an alcoholic solution or salol or resorcine. In order to release confined pus, punctures should be made with the thermo-cautery. The cavities left by sloughs should be dusted with powdered salol or iodoform, or washed out with solutions of the same.—*Provincial Medical Journal.*

Gallobromol.—According to Lépine this is the pharmaceutical name for dibromo-gallic acid. It is gallic acid in which two atoms of bromine have replaced the two remaining hydrogen atoms of the benzin radical. It occurs as fine white needles, very soluble in alcohol, ether, and boiling water, and sufficiently soluble in cold, so that it can be administered in solution. Internally it is prescribed in wafers in dose of seven grains. Thus administered it may give rise to gastric heaviness. It is used as a bromide in epilepsy, for the purpose of diminishing the attacks. Basing an opinion upon a small number of cases, it appears to be less efficacious than the potash salt. In other conditions, notably a case of chorea, which is not likely to be much benefited by the bromide of potash, it seems to be of use. Although an organic combination of bromide might be assumed to be less likely to be dangerous than an inorganic salt, yet the author says that caution must be observed, and that two drachms and a half per day is to be used with care.—*La Semaine Medicale.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, November 25, 1893.

MEDICAL BOARDS AND HOSPITAL MANAGERS.

A RECENT attempt to bring before the medical profession the question of the treatment of Medical Boards by the Managers of Hospitals, provoked unfortunately a somewhat sharp discussion at the Academy, and showed again how quickly a certain number of physicians will side with the higher and moneyed powers, and against their medical brethren.

The facts in regard to the New York Infant Asylum have been presented to our readers, and we need not weary them again with the details.

On the one hand was a Board of Physicians which had been exercising the privilege of nominating to the Board of Managers the men who were to serve as visiting physicians with them. This Board was suddenly shown that it did not possess the privilege it had been exercising, and was categorically refused it by the President. We are credibly informed also that the members of the Medical Board, most of whom had served faithfully for years, were treated with discourtesy, personal interviews being denied, written communications ignored, and contemptuous epithets applied to the medical men. No attempt at conciliation was made, and no expression of appreciation of the medical services was expressed. Yet these gentlemen had been instrumental in reducing the mortality-rate at the Maternity to as low a rate as in any of the most famous metropolitan institutions. At great personal sacrifice, also, several severe epidemics had been stamped out, and the medical status of the institution placed on a high level.

Despite this, these gentlemen were refused the ordinary attention given by any "boss" to his servants who have a grievance.

Taking all the facts into consideration and allowing weight even for the technicalities by which Boards of Managers hedge in their rights, we believe no fair-minded person could deny that the Medical Board was treated with gross injustice. We are surprised that any reputable medical men could be found to come to the Managers' defence. We cannot imagine any just reason for so doing.

We do, however, appreciate the feelings of some who do not wish the Academy to be made the scene of acrimonious debate. These gentlemen are perhaps unduly hyperæsthetic on this point; for the Academy is not too good to be the champion of a just cause. However, discussion and difference of opinion have arisen owing to the activity of the partisans of the Managers. These latter gentlemen are no doubt now chuckling over the doctors' quarrels and congratulating themselves on the ease with which laymen can play fast and loose with their medical servants. Nevertheless, we venture to predict that there will be some very radical changes in the conduct of the New York Infant Asylum; and that it will be a long time before physicians of repute will connect themselves with an institution whose management has so thoroughly discredited itself.

A COMMON TONGUE FOR SCIENTISTS.

THE recent meeting of the Pan-American Congress in Washington has once more forced upon the notice of medical men the desirability, if not the necessity, of having one language to serve as a common means of communication between those of different countries. The official languages were four in number: French, Spanish, Portuguese, and English. There was doubtless a goodly number, especially of the South American adherents of the Congress, who could understand two of these tongues, a smaller number may have been more or less familiar with three; but we venture to say there was not a score of those present who could understand everything that was said in all of these official languages. But this was not all. Professor Czerny, of Heidelberg, was invited to attend the Congress, and in reply to the invitation published an open letter in a German medical paper, to the effect that neither he nor many of his colleagues would attend unless German were added to the list. The managers of the Congress thereupon adopted a rule making it allowable to speak in any language. Had many of the invited guests availed themselves of this privilege, the confusion of tongues would have been sorry indeed. It may be said, without fear of contradiction, that there was not one of those whose good fortune it was to assist at the meetings of the Congress, who would not have found his pleasure greatly enhanced had the proceedings been conducted in one language, understood of all and recognized as the sole official tongue.

This question of a universal language for the convenience of scientists has been discussed before learned societies in this country and elsewhere, and the desirability of adopting such a language has also been dwelt upon at different times in these columns. If anyone of the three tongues, French, German, and English, which are always the official languages at the international medical congresses could be chosen, English would have the strongest claim, for that is the one spoken by the greatest number of people in the civilized world. According to an estimate of Mulhall, English is spoken by 111,100,000 people, while 75,200,000 speak German, and but 51,200,000 speak French. Forty years ago, indeed, Jacob Grimm, in his treatise on the origin of language, called English a world language, and expressed his belief that it would prevail more and more extensively throughout all portions of the earth. But national jealousies render the choice of any one of these three tongues impossible, so we must look elsewhere for a language that would be acceptable to all.

Some time ago, in the course of some remarks upon this subject, we suggested Greek as a language which might,

with propriety, be adopted as the medium of communication between scientific men of different countries. It is a tongue intimately associated with medicine and other branches of learning, a large number of scientific terms being derived from it; it is a living language spoken by several millions of people; and it is, when taught according to modern methods, not a difficult speech to learn. In a brochure recently published,[1] Dr. Achilles Rose, of this city, pleads earnestly and forcibly for the adoption of this language by science. There are many men, even some college professors of Greek, who call it a dead language, and regard the Greek spoken to-day in Athens as a patois made up chiefly of Slavonic and Turkish words, though written with ancient Greek characters. Dr. Rose demonstrates the absurdity of this view, and also shows that it is not very difficult for adults to acquire a good conversational knowledge of Greek. The monograph is most interesting, and we hope the accomplished author will prepare a translation of it for the benefit of his English speaking colleagues. The arguments presented in favor of the adoption of Greek for scientific writings and as the common speech of scientific assemblies, are most convincing; and if this beautiful tongue ever arrives at such a dignity, which we believe to be not impossible, it will owe much to the able advocacy of Dr. Rose in this and future writings; for we hope he will not let his pen rest now that he has so well begun.

FOOTBALL MORTALITIES.

Already five deaths have been reported this fall from accidents while playing football, one each from New Jersey, Indiana, Ohio, Wisconsin, and Connecticut. The two last were caused by fracture or dislocation of a cervical vertebra and crushing of the spinal cord. One of them occurred near Farmington, Conn. The second took place during a game between the elevens of the Toledo (O) High School and the Adrian (Mich.) College, which was played at Adrian a week ago. A Toledo player, Carew, says the report, "had the ball, and downed to save it. Three Toledo boys dropped to save him, and in an instant the Adrian team was upon them. When the struggle was over, Carew remained motionless upon the ground. The crowd cried, 'Fake!' but it was soon discovered that the young man's neck was dislocated." Upon examination it was found that his body was paralyzed from the chest down, and his spinal column injured, and he died the next morning without having recovered consciousness. Another member of the Toledo team was kicked in the groin, and injured so badly that he could not return to his home. A third player suffered serious injury to his right leg. English newspapers just received mention the death of a football player in West Hartlepool, "from the effect of injuries received in a football match, when he was kicked severely in the stomach."

English medical journals every year report a long list of deaths and casualties from football; but up to this year no fatal accident, so far as we know, has been reported in the United States. A mortality of five with the football season not over, however, is most startling. The general results of football playing have been heretofore considered so good as to outweigh some of the disadvantages. But the question now arises whether half a dozen deaths and hundreds of serious accidents are not too great a penalty to pay for this sport.

The football games that occur in this city have degenerated into great professional shows which are made the excuse for unlimited betting, and which end in vulgar carousals. It is quite time for college authorities to interfere.

[1] Griechisch als allgemeine Sprache der Aerzte und Gelehrten überhaupt, von Dr. Achilles Rose. New York: Gustav E. Stechert, 1893.

DOCTORS AND DISPENSARY BOARDS.

In a recent discussion on the dispensary system, held at the Academy of Medicine, several laymen who are connected with the management of dispensaries took part. It was most instructive to hear the dispensary discussed from the managerial point of view; and a remark made by one of the managers deserves particular attention, for, if true, it is both painful and extraordinary. Mr. C. G. Savage said that those dispensaries in New York, on whose Boards of Managers there were doctors, were the worst in the city. We trust that Mr. Savage has facts to sustain this remarkable statement.

So far as our knowledge and information go it is quite untrue. The Out-patient Department of Bellevue Hospital, for example, is managed by a Board of Physicians, and since this has been done, this dispensary has performed most excellent work. Its defects are due only to the limited amount of money at its disposal. On the other hand, the Demilt Dispensary, which used to stand in good repute among the profession, has lost much, if not all, of its prestige through the narrowness of its managers, and though excellently located, and possessing more than the usual supply of funds, its patronage remains practically the same that it was twenty years ago. Meanwhile, two new dispensaries started on the East Side during this time, and managed entirely by physicians, have so prospered that they do more work than their older neighbor. We do not believe, therefore, that Mr. Savage's point was well taken. There are plenty of physicians who possess both professional knowledge and business capacity. If such men were on the Boards of Hospitals and Dispensaries, there would be much less friction, and fewer of the unfortunate misunderstandings which come usually from these Boards, regarding the medical men as paid employees, who can be dealt with as they wish.

A Spanish Medical Association.—A medical association for the protection of the interests of the profession and the fostering of professional brotherhood has been founded in Madrid, under the title of "Asociacion del Colegio Medico de Madrid." The meeting for organization was held under the presidency of Dr. Julian Calleja, Dean of the Faculty of Medicine, and a member of the Spanish Senate. Among the members of the provisional committee of management are the Marquis de Guadalerzas, the editor of the *Siglo Medico*, Dr. Angel Pulido, and most of the leaders of the profession in the Spanish capital.

Clams and Cremation.—A small crematory was recently built in a New England town, and the dedication ceremony consisted in a clam-bake, the oven of the crematory being used to cook the clams and corn.

News of the Week.

Professor Pozzi, of Paris, while on a visit to this city, was the recipient of marked attention by gynecologists. Dr. J. Byrne, of Brooklyn, gave him a dinner on the evening of Thursday, November 16th, and Dr. W. Gill Wylie, of New York, one on Friday evening following. On the latter occasion the leading representatives in the different branches of medicine were present, making as distinguished a company for its size as has been gathered for a long time about one table. There were no regrets before or after the dinner.

Since the Financial Crisis Detroit physicians are said to have increased their fees. We might do it here for all the notice patients would take of it.

Manual Treatment of Bow-legs.—Dr. Samuel Ketch, of this city, writes: "In the MEDICAL RECORD of November 18th appears an abstract of an article on the 'Manual Treatment of Bow-legs and Knock-knee,' read by me at the annual meeting of the American Orthopedic Association, held at St. Louis, September 19th, 20th, and 21st. In it I am reported as advising against 'trusting this work to the mother,' and urging that 'the child be brought to the surgeon three times a day.' What I really stated was that I preferred to carry out the manual treatment by exercises personally as often as practicable, but advocated the co-operation of an intelligent parent or nurse. Also that these exercises should be practised at least three times daily, and in this way presume the error arose regarding 'three visits a day to the surgeon.'"

New Medical Organization of the National Guard of New York.—A new hospital service order has been prepared by Surgeon-General Bryant. It is in brief an order to establish a hospital corps for the National Guard, to take the place of the detail of four from each company, which constituted the cumbersome ambulance corps. The new hospital corps is to consist of a detail of eight from a regiment and four from a battalion. No division smaller than battalion is recognized. These details are to be placed under the command of the medical officers and trained as hospital assistants. They are to receive instructions first in aiding the injured, and where hospitals are organized, as at the State camp, they will be utilized as nurses, cooks, attendants, and doctors' assistants. At camp the most they will have to do will be to carry men who have been overcome with heat to the hospital wards and in reach of the doctor. In case troops are called out to suppress rioting, as at Buffalo, a field hospital would probably be organized and the corps would be placed on duty there. The new order also provides for an emergency increase in the number of the hospital corps by giving commanders of companies the power to detail men to act as "litter bearers."

Spelling Made Hideous.—The *Medical Press and Circular* prints the following Philistine editorial: "Many of the American medical journals are now becoming so hideous in the matter of spelling that it is a difficult matter even for an ordinary educated English medical man to read them without wishing to throw up his task in disgust. The van in this insane effort to appear novel is led by the Philadelphia *Medical News*, and now we learn that the editor of that journal is bringing out a new edition of a 'Medical Dictionary of Terms,' in which all this new-fangled and absurd method of spelling will be incorporated. The rising generation of young American medicos are to be pitied if they are required to adopt the teaching in orthography which will obtain in this 'Dictionary.' We are glad to see that some of our leading contemporaries in the United States have not been led into disfiguring their columns by such words as 'chemic,' 'bromid,' and 'physiologic,' together with others equally absurd and hideous. The introducer of this *fin de siècle* method of spelling affirms that no argument can be advanced against it. But what about the rules of grammar and prosody so far as the English language is concerned. Perhaps under the circumstances it would be best at once to bring out a book dealing with the subject of 'The American Language: its Grammar and Orthography,' and then there would be no difficulty in showing that the American method of spelling had nothing to do with the English language."

Leprosy Decreasing.—The report of the "Leprosy Commission of India," fills a bulky volume of 456 pages. The geographical distribution of leprosy throughout India is lucidly set forth in three large maps, colored. These show the changes in the number and proportion of lepers in the three Presidencies, according to the three census returns of 1871–81 and 1891, and the most affected districts. The last, that of 1891, exhibits a general decrease of leprosy all over India. A very satisfactory condition brought about chiefly by the efforts made of late years to improve the sanitation of the country. Yet one William Tebb says leprosy is increasing, on account of vaccination.

A Physician's Gift to San Francisco.—Dr. Levi C. Lane, of San Francisco, has presented to the city of San Francisco a large building with two wings, each two stories high, which he has had built for a fully equipped hospital, to be used as an annex to the Cooper Medical College of that city.

A Home for Epileptics in Brooklyn.—An effort is on foot in Brooklyn to establish a non-sectarian home for epileptic patients. A suitable lot has already been secured, and it is desired to raise a building fund of not less than $10,000.

The Date of the Introduction of Syphilis into Europe.—This subject is discussed by Professor Binz. The conclusion he comes to is that constitutional syphilis was unknown in Europe before 1493, in which year Columbus arrived at Barcelona from Haiti and brought with him the disease, which his followers had contracted among the Haitians. It seems that the complaint had been known and general for a very long time in Haiti and was not at all severe at that time.

Manitoba Medical College has upward of a hundred students this session. The college has been refitted.

The Total Number of matriculated medical students in the universities of the German Empire in the summer semester of 1893 was 8,838.

The Dominion Medical Monthly is the name of a new medical journal published in Toronto.

Cincinnati Physicians in Politics.—The Cincinnati Academy of Medicine has shown that it may be a power for good in politics. The *Lancet and Clinic* says: "In

the vote on the Hamilton County Senatorial ticket there were cast for the Democratic candidates who were recommended by the Academy of Medicine an average of 2,672 votes more than the number cast for the candidate not so recommended, while on the Republican ticket the candidate recommended by the Academy of Medicine received 914 more votes than the average number cast for the two candidates not so recommended; which indicates that in the face of a singularly partisan election, the members of the medical profession were able to poll an influential vote in Hamilton County of 3,586 in favor of candidates pledged to support a non-political measure, and against political party principles. Those 3,586 votes are the representatives of a very potent power in politics." The Cincinnati profession is trying to secure proper medical legislation and to "down" quackery and humbug. We wish it success.

Reviews and Notices of Books.

Introduction to the Catalogue of the Collection of Calculi of the Bladder, etc, Removed by Operation. By Sir Henry Thompson, F.R.C.S., etc. Pp. 39. London: J. & A. Churchill. 1893.

This is, as its name implies, a preliminary catalogue of the collection of calculi presented, by the distinguished genito-urinary surgeon, to the Hunterian Museum of the London College of Surgeons. It is intended to issue at some future time a more elaborate catalogue. This preliminary announcement is largely statistical, and as such useful for consultation.

Transactions of the Medical Society of the State of Pennsylvania for the Year 1893. Pp. 288. Philadelphia: Binder & Kelly. 1893.

Transactions of the Medical Society of the State of Michigan for the Year 1893. Pp. 368. Detroit: John Bornman & Son. 1893.

Both volumes are creditable to the profession of the States named. The list of topics discussed is timely, and an intimate knowledge with the latest advances of medical science is everywhere displayed.

Transactions of the American Laryngological Association. Fourteenth Annual Meeting, held at Boston, June, 1892. Pp. 118. New York: D. Appleton & Co. 1893.

Nineteen papers upon current topics in rhinology and laryngology, make up the present volume. The high standing of this society, both here and abroad, is fully maintained by the present Transactions. Several new instruments are figured and described.

The Throat and Nose and their Diseases. With one hundred and twenty illustrations in color, and two hundred and thirty-five engravings. By Lennox Browne, F.R.C.S.E., Senior Surgeon to London Throat Hospital, etc. 8vo, Pp. 734. Fourth edition. Philadelphia: Lea Brothers & Co. 1893.

Although the present edition contains but eighteen pages more than its predecessor, the process of condensation has been carried on to such an extent that it contains considerably more information, which it is needless to say is brought up to date in the fullest possible sense of the term

Rarely has any treatise on any specialty met with a more cordial reception than the one under consideration. While the author is, like all writers of firm conviction, a trifle dogmatic at times, his mind is open to truth from every quarter, and his pages are welcome alike to the general and special worker.

A portion of the space gained by abbreviation has been devoted to further details of the influence of micro-organisms in producing throat diseases. The bacteriology of diphtheria is tersely reviewed, and the writer gives his adherence to the now commonly held views regarding the bacillus and pseudo-bacillus. He adheres to the American and continental idea, that the malady is primarily a local disease with secondary manifestations.

Under the heading of croupous rhinitis, in which he includes the fibrinous or plastic forms, a statement is made to which exception may be taken. It is declared that no one has found the Klebs-Löffler bacillus in the exudate. As a matter of fact, it has been found by several observers.

The chapters on syphilitic and tubercular laryngitis are well written. The use of the intubation-tube for stenosis from these processes seems not to be as much followed in England as in this country. Encouraging mention is made of the lactic acid treatment of Krause and Hering for tubercular laryngitis, though the enthusiasm of the continental workers is not shared by their English *confrères*. He has not found the method beneficial in purely laryngeal cases, for which he prefers menthol in olive oil as recommended by Rosenberg.

A most generous recognition is given to the work of American laryngologists, and the references to authorities appended to each of the principal chapters is an arrangement to be commended.

The main feature, perhaps, of the present edition has been the expansion of that portion which deals with the diseases of the nose. He pays his attention to Sir Christopher Heath by saying that "it is to be greatly regretted that a general surgeon, who may be said to have won his spurs by a prize essay on diseases of a region involving the accessory cavities of the nose, should have permitted himself and been permitted to recently deliver, in one of our royal colleges, a lecture which had for its avowed purpose the pouring of ridicule on the progress of nasal surgery at the hands of specialists." "Derision," he adds, "has recoiled on the derider."

The author is to be commended on the excellence of his work, and congratulated that a new edition has been so speedily called for.

A Text-book of Medicine for Students and Practitioners. By Adolf Strumpell, M.D., Professor and Director of the Medical Clinique at Erlangen. 2d American Edition, translated by permission from the 2d and 3d, and thoroughly revised from the 6th German Edition, by Herman F. Vickery, A.B., M.D., Instructor Clinical Medicine, Harvard University, and Philip Coombs Knapp, A.M., M.D., Clinical Instructor Diseases Nervous System, Harvard University; with Editorial Notes by Frederick C. Shattuck, A.M., M.D., Jackson Professor Clinical Medicine, Harvard University. New York: D. Appleton & Co. 8vo, pp. 1001. 1893.

The elaborate titular display which presents itself to the reader is in reality the broad and inviting porch through which he passes to the realization of what can be found within; what impresses one on the perusal of the work, and in the critical examination of the chapters, is the earnestness of purpose of the author to teach intelligently, modestly, and effectually the inward significance of pathological indications as bearing upon clinical phenomena. No doubt is left in the mind of the student as to the eminent qualifications of the teacher and his rightful appreciation of the needs of his readers. The work, in fact, has infused into it a practical element which never fails to develop an interest in the subjects treated. The salient points of disease, its significant symptoms, and more especially the pathological explanations of the same, are grouped in such a natural and logical order that nothing is left to be desired in the premises. The arrangement of subjects is simple and easy of reference,

and is supplemented by an elaborate and very useful index. Withal there is a charming conciseness of style which is rather unusual in a work of its kind, and adds very considerably to its usefulness as a ready yet complete work of reference. Hence we are not surprised to find that it has won for itself a place as a leading text-book in many medical schools, not only in Germany but in this country. That it is destined to remain so will go without the saying. The translators and editor have adapted it to the necessities of the American public by omitting the prescriptions and references to the German pharmacopœia, and substituting therefor, as far as seems necessary, leading preparations from the American pharmacopœia, and on other points reconciling the details of American and European practices. The illustrations are sufficiently numerous, and serve a good purpose in fixing certain important diseased conditions referred to in the text. This is particularly noticeable in the article on nervous disease, which is exhaustively concise and fully up to the date of recent investigations in this rapidly growing branch of medicine. It is as a whole a well-arranged, concisely written, and valuable book for ready reference and careful study.

A System of Genito-urinary Diseases, Syphilology, and Dermatology. By various authors. Edited by Prince A. Morrow, A.M., M.D. Vol. I. D. Appleton & Co.

The first volume, which treats of genito urinary diseases, has been written by thirty-two of the best known men in that line of surgery, and the subjects have each been dealt with carefully.

While it cannot be said that anything absolutely new has been given, the book has great value, and will no doubt be well received by the profession. It is profusely illustrated, and will thus aid the reader in understanding the pathology, and the use of instruments more clearly.

The greatest objections to the work are the modes of treating spermatocele, in which the injection of carbolic acid is not mentioned; but the author prefers either the open operation of Volkman or simple tapping. On the other hand, the treatment of varicocele is not up to the most advanced method, as the subcutaneous ligature is alone given; in extreme cases the author advises ablation of the lower end of the scrotum, while a free excision of the enlarged veins is not spoken of.

Atlas of Electric Cystoscopy. By Drs. Emil Burckhardt and E. Harry Fenwick, F.R.C.S., England. With thirty-four colored plates embracing eighty-three figures. London: J. & A. Churchill, 11 New Burlington Street. 1893.

This Atlas, of seventy octavo pages, contains, as the conjoint work of two observers in distant cities, a series of personal observations in electric cystoscopy which will prove of the utmost value to all engaged in the mastery of this branch of genito-urinary work. The part contributed by Burckhardt comprises the drawings from his German edition, which were with one exception taken from life and drawn by the author himself. The first five plates illustrate the normal bladder, the rest being devoted to pathological states.

The impression is made of accuracy of drawing and strict reproduction of what was actually seen by the observer.

The work, which is published at 21 shillings, will interest all engaged in genito-urinary practice and those learning cystoscopy.

Transactions of the American Association of Obstetricians and Gynecologists. Vol. V., for 1892. 8vo, pp. 528. Philadelphia: W. J. Dornan. 1893.

This volume, which is of usual size and elegant make up, contains a great deal of practical material for the working gynecologist, and covers a variety of subjects. Most of these refer to the fashionable uterine (hysterectomy) and abdominal (laparotomy) operations. We notice with some surprise, however, that the gynecologists are appropriating the kidney in their field of operations; possibly, however, the urethral connection is sufficient to establish the claim. The great merit of all the papers is that they are short and that the discussions are practical and to the point. The volume is illustrated with striking pictures.

How to Judge a Horse. A concise treatise as to its qualities and soundness, etc. By Captain F. W. Bach. 12mo, pp. 180. New York: William R. Jenkins.

This is a little work which will doubtless be of use to the physician who may wish to know of points about a horse either for purchase or use. It includes matters connected with the anatomical make-up of horses, bits and bitting, saddles and saddling, driving and correction of bad habits, with extracts from the Rarey and Rockwell methods of training. It contains thirty illustrations, which are, however, not of high artistic merit.

Transactions of the Medical Society of the State of New York for the Year 1893. Published by the Society. 8vo, pp. 540.

Transactions of the New York State Medical Association for the Year 1892. Edited for the Association by Ogden C. Ludlow, M.D. Published by the Association. 8vo, pp. 834.

There is no State save that of New York which has two distinct State organizations that can publish two volumes of transactions, respectively, each year, and make such a good showing of scientific work. Taking the volumes side by side, we are almost tempted to make a comparison which would hardly be in favor of the older organization, but it is with no such spirit that we wish to deal with them. The quality and quantity of material in both are excellent, indeed, much beyond the average of transaction literature, and we can offer only congratulations rather than criticism.

A Manual of Medical Treatment or Clinical Therapeutics. By I. Burney Yeo, M.D., F.R.C.P., Professor of Clinical Therapeutics in King's College, London. 2 vols., 12mo, pp. 1374. Philadelphia: Lea Brothers & Co. 1893.

The object of this work is the study of disease from the point of view of treatment. It is such in a much broader sense than usually obtains in books of its class, in that the reasons for the therapeutical management of the different diseases are studied in their pathological relations to their symptoms and the well recognized effects of drugs upon certain conditions. Thus what the author terms rational indications for treatment are made apparent, in these days, when so much time and labor are expended in the study of purely pathological processes and their direct bearing on diagnosis, that the much neglected element of detailed treatment is duly recognized as the pivotal point of practical application for the reader. The arrangement of the subjects is the natural division of the various regions of the body, and the discussion of the different ailments has a distinctly practical turn toward the main purpose of the book. Standard formulæ are introduced from eminent practitioners where necessary, and all the drugs of recognized value are grouped in the order of their importance. The dosage receives careful attention, which is a feature that cannot be too highly commended. It cannot fail to be an exceedingly useful, suggestive, and instructive work to the physician who wishes to be well up in the present advanced and scientific therapeutics of the day.

The Relation of scrofuloderma to lupus is best explained by Unna's and Leistikow's theory, that scrofuloderma is an affection caused by the symbiosis of staphylococcus pyogenes aureus and bacillus tuberculosis—*i.e.*, scrofuloderma is a case of "mixed infection."—Smith.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 2, 1893.

D. B. St. John Roosa, M.D., President, in the Chair.

The Late Dr. John C. Peters.—Resolutions eulogizing the life-work of the late Dr. Peters were read by Dr. F. A. Castle and adopted by the Academy.

The Importance of Early Attention to the Disability Caused by Infantile Paralysis.—Dr. A. B. Judson, in presenting a paper on this subject, said: I propose to consider briefly the question whether a certain class of patients should not be committed more entirely and more early than they are to the care of the orthopedic surgeon—a consideration as interesting to the family physician as to the orthopedist, as they meet in a friendly alliance to secure the greatest benefit for their common patient.

I refer to patients disabled by infantile paralysis. The child has passed through the stage of onset. Ergot, electricity, and massage have produced their legitimate effect, and we will say that the eighteen months which are believed to be the limit of spontaneous recovery from the paralysis, are passed. The friends and the patient, with many grievous misgivings, have become reconciled, or at least accustomed to disability and deformity which now seem to change for neither the better nor the worse.

What can now be done? The question whether such a patient may not yet receive benefit from the advance of scientific knowledge, or from the daily increasing facilities for the application of knowledge, will surely spring up in the parental heart.

Now, it is curious to note that the deformity in these cases is often found upon analysis to be a disability more than a deformity. Take a case, for example, in which the knee cannot be completely extended. When the patient is sitting there is no deformity, but when he stands the apparent deformity is due to a disability—an inability to extend the knee. How easy it would have been to prevent contraction of the hamstrings by providing for their repeated elongation by complete extension of the knee, easy comparatively for one who has given himself to such details and is habitually mindful of their importance, and free from the manifold cares which beset the average practitioner. And it should be borne in mind that cases sometimes occur in which shortening of the tendons begins in a manner not well understood, at a very early stage, before simple desuetude can be fairly accused of being the author of the mischief. The prevention of muscular and tendinous shortening, then, should receive attention on the part of the early observer of the case. It is not an obscure and difficult point, but one which has perhaps escaped the consideration to which it is entitled.

To recur to the disabled knee — and this part of the anatomy is used simply as a convenient example to illustrate points in the pathology and treatment applicable to all the joints—if the knee is kept extended at those times when walking is attempted, not only are the muscles and tendons kept in normal elongation, but the general welfare of the limb is assured. Neglected patients may be seen in the streets walking laboriously with extension of the knee produced by the hand pressed firmly at every step on the lower part of the thigh when the weight of the body is on that limb. It is doubtful whether this in any case prevents the final resort to a crutch, by the use of which the limb is made to dangle, being carried about as a worse than useless burden, twining limp around the crutch, subject to the painful affections which attracts the lower extremities in cold weather in the absence of healthy circulation, and more and more impeding locomotion; unless, as has happened many times, the adult patient seeks relief and improved locomotor ability in amputation and an artificial limb. If the knee is stiffened mechanically the pressure of the weight of the body in standing and the repeated concussion of the limb as the foot strikes the ground in walking and running, will improve the tardy circulation; but beyond this, and better than this, will be the development of unused muscular fibres and special groups of muscles, by whose action important motions will be acquired which would have been impossible if the limb had remained in suspension.

Now, in order to keep the knee firmly extended under the weight of the body in standing and walking, and to give use and development, as far as may be, to the fragmentary muscular system of the limb, apparatus is required; but it will not be obtained without authoritative medical advice and prescription, and as a rule the family physician cannot be expected to work out the tedious processes incident to treatment of this kind. It falls to the lot of the specialist, who can well bear the inconvenience attending final results which are more or less imperfect, after satisfying himself that he has done all that science permits to be done, and whose daily and hourly mastery of the necessary details has enabled him to reduce perplexing and complicating conditions to familiar routine. Treatment of this kind lies far outside ordinary practice, in which the physician renders such signal service. He makes his diagnosis, advises, prescribes, remains on guard against complications, foresees the crisis and prepares for it, leads the way cheerfully through convalescence; and medical science, so dear to us all, finds but another illustration of its power and beneficence. In one home a wasting fever has been finally resolved and the patient rises in perfect, or even improved, health from a bed where the grim alternative has been decided in his favor. In another the children have been happily carried through the perils of infection and resume their places at the table. But in the special practice adapted to the cases under consideration there is no fear of a fatal result and no rejoicing, and the object sought is at the best a palliation. But who will say that important service has not been rendered? for it should be remembered that the conservative and plodding practitioner along this line has for an ally one of the most potent influences in nature in the growth of the body. The popular reliance on this force, expressed in the common question—"Will the child not outgrow the ailment?" whatever it may be, is not always misplaced. Happy the physician who, imparting his confidence to the patient's friends, and relying on the exact science of the physicist, sees grace and power growing out of deformity and helplessness.

A good general rule in the treatment of deformity in a growing child, is to keep the part as near as possible in the desired shape as much of the time, day and night, as is practicable, so that the increment shall be on the right side of the dividing line between the normal and abnormal. The familiar proverb says: "As the twig is bent the tree's inclined." In the troubles following infantile paralysis the principle should be extended. We should not only persist in keeping the part as near the normal shape as we can, but we should also give as wide play as the crippled condition of the limb will allow, to the functions of motion and weight-bearing. From the very earliest attempt to walk, or to make use of the muscles and joints which are imperilled by the cord lesion, extraneous assistance should be afforded. It should not be said off-hand that the child is too young. The first and repeated question should be: Is the child not yet old enough, or is he not already giving sufficient evidence of a desire to make use of the questionable muscles and joints, to make assistance desirable or necessary?

When efficient treatment is begun it is easily continued. Improved ability is at once appreciated by both parent and child. It is well that such is the fact, for improvement does not stop with infancy or childhood. The process is slow and prosaic, but the benefit cannot be over-estimated in the opinion of the one who is in

the best position to judge of its value. A slight improvement in the gait, or an ability to walk a little faster or a little further without fatigue, confers lasting happiness, and the patient and physician are thus encouraged to go on to new achievements until, with one step after another gained, the outcome is an adult well able to follow the ordinary pursuits of life, in place of a being who had looked forward to hopeless dependence.

Dr. Hubbard said that if he should offer any criticism upon the paper, it was that it had not presented the case strongly enough in favor of orthopedic treatment. Many of the deformities which occurred after infantile paralysis might be avoided if the orthopedist were consulted earlier in the case, and he would put that period much in advance of eighteen months. He did not believe the application of a brace would have a tendency to interfere with spontaneous recovery, if there was any likelihood of this taking place at all. In one case of complete paraplegia affecting the lower extremities, and paralysis affecting the muscles of the back, the boy was unable to stand alone, and could scarcely sit without support. By the application of braces, coupled with the use of electricity, he was soon enabled to walk about, and could now cover considerable distances without any form of apparatus. Another case was mentioned, and he closed by saying that he believed in applying apparatus before deformity had occurred, rather than in waiting until afterward.

The Cause of the Deformities.—Dr. Henry W. Berg thought the apathy shown by the profession in the treatment of cases of infantile paralysis, with a view to preventing deformities, was due to the reasoning that it was impossible to restore the function to the destroyed gray cells which had led to the paralysis. The reasoning might be logical, but the premises were false. The deformities resulting from infantile spinal paralysis were due to one or both of two causes: 1, trophic changes in the tissues of the paralyzed member; 2, paralysis of muscles.

The active trophic changes could not be prevented; the passive ones, being due to inactivity of the parts, could be prevented by treatment. A high shoe, for instance, might prevent functional lateral curvature of the spine. "But far the greater number of deformities are due to contracture of healthy muscles. Paralysis of muscles always produces disability, but the resulting contractures in non-paralyzed muscles produce deformity. The theory of unopposed muscular tonus is untenable. . . . It is evident, then, that orthopedic appliances which will do the residual work necessary to complete the restoration of healthy opponents to their normal position when they have relaxed after contraction, can prevent contractures in such non-paralyzed muscles. Inasmuch as such contractures take time for their production, the sooner the case is treated the better."

The Clinical Picture Varying.—Dr. Henry Koplik thought that not all cases presented the same clinical picture, and the physician would like to know whether the case would prove to be one of those which would recover. Yet he agreed with Dr. Judson, that the sooner the orthopedist saw the patient the better. At any rate, as soon as the electrical reaction showed that there was permanent paralysis in the muscles, mechanical treatment should begin.

Dr. E. D. Fisher said that when the child was very young, twelve or eighteen months, he would be careful not to advise too early application of instruments unless deformity was already showing itself. As long as there was no deformity and the patient could make the necessary motions in the use of the limb, he would put on no apparatus; but as soon as deformity began, or as soon as appliances would aid in the use of the member, he would advise their employment.

Dr E. D. Townsend differed from Dr. Fisher. One could not tell just when deformity first began, nor just when an apparatus would first be of service. It was best to put on a support, make sure that the motions were made in a natural line, and that the limb was kept in normal position.

Dr. A. D. Rockwell spoke briefly of electrical treatment, and said that, while it was of benefit, its value had sometimes been over-estimated. He had faith in the continuous action of the galvanic current, in spite of the efforts usually made to produce muscular contractions by the interrupted galvanic current. The former tended to preserve what vitality was left in the muscles; the interrupted current tended to destroy that vitality.

Dr. Henry Ling Taylor read as follows: After an attack of infantile paralysis, the problem usually presented is how to make the most of the mechanical and vital possibilities of a damaged limb. There is at first a well-marked tendency to recovery in many of the paretic muscles, and this can be favored by keeping them in their natural relations by a mechanical appliance. In paralysis of the ankle flexors, for instance, the anterior tibial group should be protected from the damage of stretching by mechanically preventing the foot from dropping beyond a right angle. This can be done without impediment to flexion and harmful constriction, and benefits the calf muscles as well as the flexors, since it prevents the former from becoming permanently contracted. In a similar manner nearly all the deformities so frequently following poliomyelitis can certainly be prevented.

Dr. Judson has said that there is no fear of a fatal result and no rejoicing in treating these cases. On the contrary, when the child is enabled to walk off at once on the application of proper apparatus after years of utter helplessness, as I have several times witnessed, words cannot describe the keen rejoicing of the privileged spectators. By making locomotion possible in such a manner that weak parts are not only protected from injury, but stimulated to develop, and many hitherto inactive parts brought into use, the circulation and nutrition are stimulated, and it should not be forgotten that many dormant nerve-centres are brought into play, and also that the interests of the child are wonderfully broadened. I have not only seen cold limbs grow warm, and helpless ones active, but shyness and apathy give way to cheerful activity after the application of braces had enabled the patient to walk. Inefficient support is often worse than none, because if the patient tries to walk when the apparatus causes pain, or fails to hold the limb with precision, he will inevitably shrink and withhold volition. Many of the failures charged to mechanical treatment are due to lack of skill or lack of thoroughness. In protecting weak muscle-groups, use is often to be made of the principle of "limited motion," giving the patient the stimulus and benefit of a certain amount of motion, within safe limits. However, since Dr. Goldthwait, of Boston, has shown that muscular power remains good after so long as fifteen years of disuse, we need not fear to fix a joint in a correct position, if it were necessary, rather than condemn a person to helpless deformity.

There is another point that I wish to mention regarding treatment, and that is, the persistent use of dry heat to the limb. I know of nothing else that helps the circulation so much in these limbs as the application of dry heat. I apply it by means of a small hot box into which the limb is placed, the temperature being raised to 160° to 170° F. The limb is allowed to remain in the box for fifteen or twenty minutes, once or twice daily.

Certainly the importance of early expert attention to the disabilities caused by infantile paralysis cannot well be exaggerated.

Dr. A. M. Phelps thought that if the limb were properly braced there could be no question but that the nutrition would improve; that if the limb were not properly braced, contraction must take place. An ounce of prevention was worth a pound of cure. If there was contracture when the patient was brought to the orthopedist, division of the tendon and bracing was better than prolonged bracing without the use of the knife. He would

like to have a law passed preventing instrument makers who were not physicians from treating these cases.

The President suggested that the present law was sufficient to reach all illegal practitioners.

A Word for the General Practitioner.—Dr. Reginald H. Sayre thought that many of the cases under discussion could be successfully treated by the general practitioner, and it was especially desirable that this fact should be recognized by the many who were not accessible to the orthopedist. A large part of the work of the orthopedist consisted in rectifying deformities which should not have been allowed to occur. Incidentally, he said, he had found great benefit from faradism.

Dr. A. Jacobi wished to speak briefly from the standpoint of the general practitioner, as he belonged to that class. He quite agreed with Dr. Sayre, that it was unnecessary to send all cases of infantile paralysis to the orthopedist for mechanical treatment. This could be carried out by any well instructed physician, and he remembered that it was, many years ago, at Krachowitzer's clinic. He also agreed with Dr. Sayre, that much could be done with faradism as well as with galvanism. Among other remedies to be mentioned was the subcutaneous injection of strychnia once a day, or every other day. He had found it improve the excitability and contractility of the muscles considerably.

The Coroner System.—The resolutions looking toward the abolition of the coroner system, presented at the last meeting, were taken from the table, and after some debate a committee was appointed by the President to change their form, so as to meet with the approval of all who had taken part in the discussion. The President appointed on the committee, Drs. Girdner, Armstrong, and A. Jacobi.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, October 6, 1893.

Charles L. Dana, M.D., President, in the Chair.

Mechanical Vibration in the Treatment of Disease.—The President: The object of this apparatus is to produce mechanical vibration in the treatment of disease. This method of therapeutics came into use about twelve years ago, having been first employed by a French physician who found that the tuning-fork when applied over a nerve produced a certain amount of anæsthesia and thereby relieved pain. The method was very much improved by Dr. Granville, an English physician, who devised an apparatus for producing vibration in different forms. He wrote a book upon the subject, showing that by different kinds of vibration one could produce anæsthesia and relieve pain. He advocated the method for a number of symptomatic troubles. A little later a Swedish physician devised a machine which was operated by a crank, so that very powerful, though not very rapid, vibrations could be produced in different parts of the body. About two years ago the late Professor Charcot, acting on the suggestion of clinical observation that some cases of paralysis agitans were improved by the vibration of horse-cars, etc., devised an apparatus for treating that disease on that principle. Two of his pupils then constructed what is called the vibrating helmet, which was used in the Salpêtrière. I now show you a sample of this instrument which I have had for a short time. It has been used in this country also by Dr. William J. Morton, who has kindly written me a note giving his experiences with it. It is made by a Paris electrician, and is defective in that the motor is not strong enough. By using a stronger motor, with a good driving current, decided effects can be produced in migraine, headache, cerebral paræsthesia, and insomnia.

This method of therapeutics has been somewhat further amplified by attachment to a faradic battery called the singing battery, which has a very rapid vibration and powerful current passing through a long coil. It has been demonstrated, I believe, that the passage of this very rapidly vibrating current will produce anæsthesia of the part during its flow. While I think the methods so far devised for employing mechanical vibration are imperfect, yet I believe there is something in this form of therapeutics, and it deserves further trial. In the vibrator which I have the metallic head-piece, or cap, is set in rapid vibration by a motor with eccentrics. It has also attachments for application of the vibration to various neuralgic points. I have myself relieved very severe pain of tic douleureux with it. Better results will probably be obtained when an instrument shall be invented with more rapid and powerful vibrations.

Analgesia Produced by Chloride of Ethyl.—The President also presented a vial for spraying of chloride of ethyl on portions of the skin which it was desired to render analgesic. It was extremely convenient, and was useful for the relief of local neuralgic pains and in minor surgical operations. Chloride of methyl, which he had previously used, was an imported agent, much more expensive, and, while more powerful, was less convenient.

Bacteriological Examinations made in Diphtheria by the Health Department.—Dr. Hermann M. Biggs, in presenting this subject, said he had no formal paper to offer, but thinking it desirable that the profession should know exactly what the Health Department was doing in the line of bacteriological examination in diphtheria he would make some informal remarks. About a year and a half ago Dr. Park made a series of observations on patients at the Willard Parker Hospital who were suffering from diphtheria, with reference to the presence of the Loeffler bacillus. About one hundred and fifty cases were examined. It was shown that a considerable proportion of the patients entering that hospital with supposed diphtheria were in reality not suffering from diphtheria at all, but from pseudo-diphtheria accompanied with the production of a membrane. In the summer a large proportion of cases were true diphtheria, while in the winter and early spring, when various throat affections were prevalent, more than fifty per cent. were not diphtheria. The bacteriological examinations had tallied so closely with the clinical results, that Dr. Biggs's attention had been directed particularly to them. It was observed that in the cases in which the Loeffler bacillus was not found the mortality was almost *nil*, the few fatal cases being limited exclusively to young children who developed complicating broncho-pneumonia. On the other hand, in cases in which the Loeffler bacillus was found the mortality was very high, running from twenty-five up to forty, or even fifty per cent.

Early in the present year he had made a report to the Health Department, recommending the appointment of an inspector and bacteriological diagnostician in diphtheria. After some weeks Dr. Park was appointed to this position, and since May the Health Department has been prepared to make bacteriological examination in all cases of diphtheria which were presented. In the early weeks the work was confined almost solely to cases which were sent to the department by physicians, and cases in which there was some doubt as to the diagnosis which came under the direct observation of the Health Department. Later, as the work became more thoroughly systematized and knowledge of it became more widely diffused throughout the profession in the city, it was extended to making bacteriological examinations in all cases of suspected diphtheria occurring in tenement houses and boarding-houses, unless the physician in attendance objected.

In order to facilitate the work depots have been established at different points in the city where culture tubes could be obtained by physicians for making inoculations. After being inoculated these were returned to the depots and are collected by the department for examination. Printed directions were given along with the tubes. Circulars of information regarding the work had been delivered, by messengers, at the office of every physician in the city. There were two slips to be returned with the

tubes, one for primary cultures, the other for secondary cultures, which were made later in the cases, to insure freedom from contagion. On the first slip was the name of the maker of the culture, the day, the time of day, the name, age, and address of the patient, the name and address of the attending physician, the duration of the disease, how contracted, location of the membrane, was the inoculation satisfactory, the clinical diagnosis. The second slip contained the number of the culture, the date, name of patient, address, name of inspector, laboratory number, and at the bottom of the slip was the question, "Is the place ready for disinfection if the culture is found free from bacilli?" "Designate the number and location of the rooms to be disinfected." One of these slips was put in with each box containing the necessary tubes, etc., together with instruction how to make the culture.

"HEALTH DEPARTMENT, NEW YORK, July, 1893.

"CIRCULAR OF INFORMATION CONCERNING THE USE OF BACTERIAL CULTURES FOR THE DIAGNOSIS OF DIPHTHERIA.

"Recent bacterial investigations have shown that a considerable proportion of the cases of pseudo membranous and exudative inflammations of the throat and upper air-passages, commonly considered as diphtheria, and having the anatomical appearance found in diphtheria, are not true diphtheria. These cases may be called pseudo- or false diphtheria.

"It has also been shown that a considerable number of cases, which are apparently false diphtheria, prove, on bacterial examination, to be true diphtheria. While in true diphtheria the mortality is very high, and the danger of transmission to others is great, in false diphtheria the mortality is low and the danger of infection slight. The differential diagnosis between true and false diphtheria can be made by bacteriological examination within twelve hours, while without this the differentiation is difficult or impossible.

"The Health Department is now prepared to make use of bacterial cultures for diagnosis in all cases of suspected diphtheria occurring in the city, and desires that in every case either the physicians should themselves make the inoculations, or should authorize an inspector to make them. They should be made in every suspicious case at the earliest possible moment, for during convalescence the specific organisms often disappear from the throat and the full benefit of a positive diagnosis is not obtained unless it is made early in the disease.

"The inoculations are made by gently rubbing a cotton swab against the throat, and then drawing it over the surface of the culture-medium. When the physician himself desires to make the culture (and this is usually the better plan, for it can be done earlier and is more agreeable to the family), he can obtain, free of cost, a culture-tube and swab, and the simple directions necessary for their use, from druggists designated by the Board. After the inoculation the tubes are to be returned at once to the druggist from whom they were obtained. The tubes will be collected by the department every evening.

"In cases where an inoculation has not been made by the attending physician, the medical inspector will make one, unless for any reason the physician requests that none be made when he notifies the department of the case.

"The diagnosis will be ready by noon of the following day. The attending physician can obtain this immediately, by telephoning to the laboratory, or when this is not done, he will be notified by mail. Cases which prove to be false diphtheria will not be visited by the Health Department inspectors. Cases, on the other hand, which prove to be true diphtheria, will be subjected to the usual rules and regulations covering contagious diseases.

"All communications on this subject should be addressed to Dr. Herman M. Biggs, Chief Inspector Pathology, Bacteriology, and Disinfection, No. 42 Bleecker Street (Telephone '1191 Spring').

"By order of the Board of Health,

"CHARLES G. WILSON, *President.*

"EMMONS CLARK, *Secretary.*"

After the culture was made the box and tubes were returned to the depot, and late in the afternoon of each day they were collected from the various depots, where they had been kept in culture ovens until taken to the central depot. At the laboratory they remained in the brood oven until the next morning, when the examination was made and the reports were sent back to the physicians who had charge of the cases, and also to the inspector of the district. Dr. Biggs said that some idea of the extent of this work could be obtained from the fact that, two days before, forty-nine tubes had been returned for examination, twenty-nine of which were primary, and twenty secondary cultures. It had been found, especially in the tenement districts, that in a great many cases after the membrane had entirely disappeared from the throat, and the children were apparently well and playing in the streets, the throat still contained the Loeffler bacillus. Pure, or almost pure cultures had been obtained even as long as ten days or two weeks after the membrane in the throat had entirely disappeared. In one case the child had no membrane of the throat, but had a nasal discharge in which was found the Loeffler bacillus five weeks after apparent restoration to health. In the Willard Parker Hospital, where frequent applications of bichloride of mercury were employed—one to four or five thousand—it had been found that culture of the Loeffler bacillus could not be obtained after forty-eight hours.

Being guided by the results of these examinations it had been decided not to allow cases occurring in tenement-houses to be discharged or returned to school until secondary examination showed the absence of the Loeffler bacillus. At the end of eight days, or earlier, if the membrane had disappeared, a second culture was made by the inspector of the district, and then if the Loeffler bacillus was found to be absent, the case was referred for disinfection of the apartments, etc. If the Loeffler bacillus was found to be present, the case was kept under observation three or four days longer, when the culture experiments were repeated.

The Health Board was determined to make very strong efforts to limit the prevalence of diphtheria in the city, and it had been determined to remove a much larger proportion of them than formerly to the hospitals, especially from localities where the apartments were small, the number of children in the house large, where the parents were ignorant or negligent, and where it was impossible to do anything in the way of isolation. Patients would be removed forcibly if necessary. The hospital facilities of the department had increased so much this year that a much greater number of patients could be received and cared for. There would be accommodation for about one hundred cases of diphtheria in the Willard Parker Hospital. At present the diphtheria cases in tenement-houses were to be visited at least every other day by inspectors, and as complete isolation was to be obtained as possible in cases which were not removed to hospitals. At the end of the disease, as perfect disinfection was to be practised as the circumstances would allow. The disinfection was to be applied to the whole flat, or whole apartment, if there was any reason at all to suppose that the whole of it had been infected. Carpets were taken up and sent, with bedding and other articles, to the station at East Sixteenth Street, to be disinfected by steam. The floors were washed with bichloride solution, sulphur was burned in the apartments, three pounds to the thousand cubic feet of air. While it must be admitted that the disinfection was not ideal, yet it was the best that could be applied at present, and it was believed would effect considerable good. It had been shown that the

Loeffler bacillus was moderately susceptible to sulphur fumigation, that a great many of them were killed, and probably others were attenuated to such a degree that they were practically innoxious. At least experience had shown that where this form of disinfection was carried out thoroughly no secondary cases had developed.

Dr. Biggs then showed maps of the city, divided into sections, on which were platted the localities where cases of diphtheria occurred. The color of these marks was varied according to the date of development of the cases in a given neighborhood, showing whether they were primary or secondary, and indicating the probable source of the infection. One glance at the map told one of the distribution of diphtheria in the city at any given period. Some very instructive facts had become evident from these charts. For instance, it was found that in August four cases of diphtheria had occurred in a house on East Seventy-third Street; the second week there were two cases; third week one case; first week of September one case; second week two cases; third week one case. Thus there had been twelve cases of diphtheria within a radius of one hundred feet. By looking over the map it would be seen that there were just such little points of infection centred here and there over the city. The probabilities were that there would be one or two cases of infection from the original one before the report reached the department, and one or two cases might develop subsequent to that report. Afterward, however, it was expected that by the efforts which the department was putting forth, the development of further cases would be prevented. The fact that the map showed that the disease spread from house to house, and from block to block was evidence of infection from the first case occurring in the neighborhood.

Dr. Biggs said that the Commissioners of Health had shown a perfect willingness to do everything which could reasonably be asked to prevent the spread and effect the eradication of contagious diseases in the city.

Dr. Abbe asked Dr. Biggs whether the cases of sore throat following scarlet fever showed the Loeffler bacillus; also, whether it was true, as had been stated very positively in some of the papers, that diphtheria was very prevalent where heaps of manure were allowed to remain at stables for some time.

Dr. Biggs replied that the streptococcus, not the Loeffler bacillus, was usually found in sore throat after scarlet fever. He had no data for answering the second question.

Dr. Partridge inquired whether the presence of the Lœffler bacillus in a case of sore throat would be sufficient reason for placing the patient in a ward among others with diphtheria.

Dr. Biggs thought there could be no doubt of it.

Dr. Partridge said that last summer a case was diagnosed as one of diphtheria on the basis of the bacteriological examination made by a competent man, yet in twenty-four hours all illness had disappeared.

Dr. Biggs said they had found the bacteriological examination and the clinical history tally in nearly every instance. Also, where the Loeffler bacillus was found there were apt to be other cases; where it was not found the disease was likely to be limited to the single case. In one of the worst appearing cases of sore throat which he had ever seen diphtheria was excluded by the absence of the Loeffler bacillus, and the patient got well.

Dr. George L. Peabody said he was acquainted with Dr. Park's work, and was gratified to know that the clinical results corresponded with the bacteriological examination. Such exact methods in diagnosis were extremely desirable. He regarded the plan which had been described by Dr. Biggs as a long step in advance.

Dr. Draper inquired how the public had received the question of isolation in diphtheria.

Dr. Biggs replied that the department had met with little trouble, but when opposition was offered it usually ceased when one of the sanitary police accompanied the ambulance. If, however, it was intended to remove the patient to North Brother Island, instead of the Willard Parker Hospital, far greater objection was usually made.

Dr. W. G. Thompson confirmed what Dr. Peabody had said regarding the correspondence between the clinical history and bacteriological examination, as it had been made by Dr. Park. He thought the scheme one of the most valuable which the Board of Health had ever adopted.

Dr. Brannan remarked that the value of a bacteriological examination in diagnosis in sore throat had been tested in the illness of his boy, who was supposed to have diphtheria until the absence of the Loeffler bacillus was proven and a favorable prognosis was made and had proven correct. He thought public opinion would sustain the Health Department because of the value of their work.

Dr. Andrew H. Smith inquired whether the recent work of the Health Department had shown any connection between diphtheria and the house sewage.

Dr. Biggs replied that where diphtheria had spread it had been traced to previous cases, sewage seemingly having had nothing to do with it.

The President inquired whether there had been a relation between dirt and diphtheria.

Dr. Biggs could only say that most of the cases of diphtheria had been in the tenement districts, four families on a floor, many of them Italians, Bohemians, and Poles.

Dr. A. H. Smith wished to know whether there had been any relation between the cases of pseudo-diphtheria and defective sanitary arrangements. Dr. Biggs being unable to answer the question, Dr. Smith went on to say that he had seen some cases of follicular tonsillitis which had seemed to depend upon bad sanitation. A striking instance occurred in an isolated country residence, where eleven cases of sore throat developed, the apparent cause seeming to be the direct connection of a bath-tub, not in use, with the pipes leading to the cesspool. In another similar instance, five cases of sore throat developed in rapid succession until the waste-pipe was repaired. Some years ago a number of cases of follicular tonsillitis occurred at St. Luke's Hospital and a sewer-pipe was found to have fallen in.

Dr. Abbe remembered the latter instance, but said it appeared to him easier to explain such endemics on the basis of immediate contagion than on that of sewage infection, for the defective sewage had existed weeks or months before the endemic of tonsillitis occurred.

Dr. Smith had understood Dr. Biggs to say that pseudo-diphtheria was not contagious.

Dr. Abbe thought follicular tonsillitis often affected whole families.

Dr. Biggs said it was not that kind of sore throat which had usually been reported to the Health Department as diphtheria when only pseudo-diphtheria existed.

Dr. Abbe regarded the question whether groups of cases of tonsillitis were due to infection or to defective sanitary conditions as a very important one, as upon its answer by the physician rested the action of the family in remaining in or removing from the house.

Dr. W. G. Thompson said there were many men working in sewers and they did not seem especially disposed to have sore throat. Their work was not interrupted by frequent attacks of diphtheria or throat affections.

The President had read that workers in the Paris sewers were not so affected, and when Dr. Peabody said that little fecal matter entered the Paris sewers, the President thought this fact should be placed on record, since the statement that workers in sewers were not especially troubled by throat affections had often been based upon assertions relating to the Paris sewers. He also thought the statistics of diphtheria would have to be rewritten, since a distinction had been made, based on bacteriological examinations, between true diphtheria and pseudo-diphtheria.

Rupture of Aneurism of Superior Pancreatic-duodenal Artery, with Symptoms of Biliary Obstruction.—Dr. Biggs then presented a very rare specimen. The patient had been admitted to Bellevue Hospital four days before,

with the history of having had jaundice about four weeks, and the day before admission having vomited, the vomit containing a considerable quantity of blood. He walked into the hospital, and soon afterward vomited somewhat altered blood. The movements from the bowels were diarrhœal, and were also composed almost entirely of blood. The morning of his death he vomited blood several times, became collapsed, and was transfused. He also had several diarrhœal movements composed of blood. At the autopsy the stomach was found to contain considerable blood, while the intestinal tract was almost completely filled with blood. The common gall-duct, cystic duct, gall-bladder, and gall-ducts far back into the liver were distended with blood. At the lower part of the common duct he found an ulceration which opened into an aneurism situated between the duodenum and head of the pancreas, involving the pancreatic duodenal artery. It had first pressed upon the common duct, causing obstruction, and later dilatation of the duct and jaundice; finally it had ruptured into the common duct and caused the hemorrhages from the stomach and bowels.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 14, 1893.

REGINALD H. SAYRE, M.D., VICE-PRESIDENT, IN THE CHAIR.

Extensive Pericarditis and Valvular Lesions.—DR. GEORGE P. BIGGS presented a heart showing the results of very extensive pericarditis and valvular lesions. It had been removed from a woman, thirty-five years of age, who gave a history of attacks of rheumatism for a period of ten years. She was first admitted to the New York Hospital in February, 1893, on account of general anasarca, but after treatment there for one month, she left the hospital very much improved. She was re-admitted on May 9th of the present year, complaining of much the same symptoms—general anasarca and dyspnœa. Examination then revealed a moderate increase in the area of cardiac dulness; the apex-beat was in the fifth intercostal space, four and a half inches from the median line, and along the left of the sternum and at the base two murmurs could be heard, one systolic, and the other diastolic. At the apex, there was a low, "rumbling" murmur accompanying the systole. There was also very marked pulsation of the veins of the neck, synchronous with the systole. The heart action grew steadily weaker, the anasarca increased, and on June 9th she died. At the autopsy, in addition to the chronic congestion of all the organs, there were extensive adhesions of the pericardium, in some places fully one centimetre thick. At the apex, was an area, eleven and a half centimetres in diameter, where the heart and pericardial sac were firmly united to the chest-wall by unusually firm adhesions. The heart was considerably enlarged, all its cavities being more dilated than hypertrophied. The muscular tissue was quite fatty. The adhesions of the edges of the tricuspid valve produced such a narrowing of the orifice that two fingers could not be passed into the opening, and the retraction which had occurred also caused regurgitation. The pulmonary valve was normal. The cusps of the aortic valve showed enormous thickening and rigidity, the cusps being fixed in a semi-closed position, thus producing marked obstruction and regurgitation. The most interesting lesion was at the mitral valve, where the orifice appeared as a semilunar slit with its convexity looking toward the left border of the heart, and the opening so small as not to readily admit the tip of the little finger. This stenosis had resulted from very pronounced thickening and retraction of the posterior or outer cusp, and thickening and apparent enlargement of the anterior or inner cusp, the latter falling over so as to completely close the orifice. It was very greatly thickened, and on its under surface was a distinct cavity produced by the blood-current as it was orced against this surface during the systole of the heart.

The speaker said that he had shown an almost exactly similar lesion of the tricuspid valve during the past winter. As the first attack of rheumatism occurred ten years ago, it is probable that the lesion of the tricuspid originated at this time.

A Cyst of the Mesentery.—Dr. Biggs then exhibited a cyst of the mesentery which had been accidentally discovered while examining the organs of a still-born child for another purpose. The cyst was situated to the right of the median line, between the folds of the mesentery, in the lower portion of the jejunum; it was oval in shape, measured four and a half and three and a half centimetres in its principal diameters, and contained colorless serum. Its walls were formed by the two layers of the mesentery. The vessels passing over it were very much distended with blood, and there were a few enlarged glands in the mesentery at its junction with the under surface of the cyst. He had never seen such a cyst, and was unable to offer any explanation for its occurrence.

A White Gall-stone.—Dr. Biggs also exhibited a very rare variety of gall-stone. It was whitish, perfectly translucent, weighed three grammes, and measured 22+18— sixteen centimetres; was ovoid in shape, and presented quite a smooth surface. It felt oily to the touch, and was composed entirely of cholesterine. It was removed from a woman, sixty years of age, and was the only stone found in the gall-bladder, which was firmly contracted about it.

Stated Meeting, September 27, 1893.

REGINALD H. SAYRE, M.D., VICE-PRESIDENT, IN THE CHAIR.

Carcinoma of the Stomach.—DR. J. H. HUDDLESTON presented a tumor of the pylorus which had been removed from a man, forty-nine years of age, a laborer, of intemperate habits. He had had good health up to early in 1890, when he began to suffer from pain in the stomach and from nausea. Two or three months later, a swelling was noticed in the epigastrium, and there was also slight emaciation, which was attributed to dyspepsia. When first seen, in the workhouse, on August 24, 1893, he was greatly emaciated and quite feeble. A tumor could be distinctly felt in the epigastrium to the left side of the median line. Inflation of the stomach with gas showed the organ to occupy apparently its normal limits. Two quarts of water were poured in without causing any distress. The first washing brought away curdled milk, which had been taken five hours, along with some dark mucus. He said he had vomited three or four times a day for several months, but never anything but food and water. There was no vomiting of "coffee-grounds" while he was in the hospital. His weight on admission was ninety-five pounds, but he emaciated rapidly, and died on September 6th. Toward the last he had very little sleep, but complained of scarcely any pain—only of weakness. The contents of the stomach were tested by the phlorglucin-vanilin test for free hydrochloric acid and a distinct reaction obtained. For five or six days before his death he had a low fever—100° to 101° F.

At the autopsy the lower lobe of the left lung was found in the stage of gray hepatization. In the pyloric region of the stomach was a tumor, three inches in diameter, which extended into the pancreas.

The points of interest in this case are: 1, Its long duration, three and one half years instead of eighteen months to two years, as is the rule: 2, the presence of free hydrochloric acid even to the last. The tumor appears to be an ordinary carcinoma.

Discussion.—DR. S. T. ARMSTRONG said he did not think the statements formerly made regarding this test for hydrochloric acid in the stomach and its significance were now accepted as correct. He had himself obtained this reaction for free hydrochloric acid in several cases where the existence of gastric cancer was indisputable.

A Myxoma of the Nose.—DR. ROBERT C. MYLES presented what he considered to be a myxoma of the nose.

He had removed it from a man, twenty-three years of age. It measured two and one-half inches in diameter when fresh, and was situated in the left nostril. It nearly occluded the posterior nares. Its external appearance strongly resembled that of a fibroma. The tumor, which had a pedicle about one and one-half inch long, was removed by snaring it off at its base.

Exostosis and Necrosis of the Vomer.—Dr. Myles also presented a sequestrum removed from the nose of a patient who gave no syphilitic history. He had occasionally had a bad odor from his nose during the past two years, and this seemed to the speaker so characteristic of dead bone that he made a long and determined search for it. He was finally rewarded by finding this sequestrum in the septum, just above the palate bone, and partially hidden by the mucous membrane. As it did not have the natural shape of the septum, it must have been an exostosis. It was very hard, and showed no tendency to disintegration or spontaneous discharge. In order to remove it from the anterior nares it was necessary to cut it with forceps. The specimen could not be anything but the rostrum or the vomer.

It is difficult to find dead bone in the nose, even with a probe; the most delicate test in his opinion is a cotton-wrapped probe, as the rough edge of the bone catches in the cotton when a probe would slip past the bone and leave it undetected.

Ulceration and Perforation of the Ilium.—Dr. S. T. Armstrong exhibited a specimen of this condition which had been removed from a woman, forty years of age, who was first admitted to his service at the Harlem Hospital on August 26, 1893. Her family and personal history were negative. Three days before admission she was taken with nausea and vomiting, followed by diarrhœa. She could assign no cause for her trouble except kicks which she had received on the abdomen from a drunken husband. On admission she vomited all ingesta; the bowels moved sometimes as often as ten times in the twenty-four hours, and the evacuations were watery and contained matter resembling curdled milk. There was abdominal pain, but no tympanites. Her body was covered with cold sweat. With a milk and lime-water diet, and sulpho-carbolate of zinc internally, she improved immediately, and was discharged "cured" in two days. On September 10th she had a slight chill, followed by fever, vomiting, and persistent diarrhœa, although there had been no dietetic indiscretion, and she knew of no cause for the relapse. Her temperature oscillated between 101° and 103° F. until the 19th, when it fell to normal. During the next two days there was only one movement of the bowels, yet she failed perceptibly, and on the evening of the 21st she died suddenly.

The necropsy showed calcareous nodules in the pulmonary apices. The heart was normal. The peritoneal cavity was filled with sero-purulent matter and liquid fæces, and there was a small, circular, punched-out ulceration in the upper portion of the ilium. There was but little congestion of the intestinal blood-vessels, a few circumscribed patches being noted here and there. There was no other ulceration, nor was there any evidence of a foreign substance in the rest of the intestine that might have caused the perforation. This perforation was probably due to necrosis, the result of vascular stasis.

The Society then adjourned.

Abscess of the Prostate should be incised as early as possible, even after spontaneous opening into the urethra, when such opening is not followed by complete disappearance of all morbid symptoms. When perineal abscess has resulted, simply opening it is not enough; the prostatic cavity must be freely opened and drained. Incision by the rectum is insufficient. Stripping up the rectum according to Dittel's method is the procedure of choice in incision of abscess of the prostate.—Zuckerkandl.

Therapeutic Hints.

Typhoid.—The simplest and most efficacious treatment consists in the administration of calomel in fractional doses. Three-fourths of a grain of calomel is given every hour for ten doses, if necessary, or till copious, soft greenish stools have been secured, a gargle of chlorate of potash being meanwhile used to prevent stomatitis.—Smakovsky.

Stomach Diseases.—I have used in gastrorrhagia from ulcer and other causes, with apparent benefit, the following:

℞. Magnesii sulphatis ..... ʒ ijss.
Magnesii carbonatis..... ʒ jss.
Pulveris acaciæ..... ʒ ij.
Aquæ ..... ad ℥ ij.

M. Sig. :—ʒ j. every fifteen minutes until vomiting ceases.

Over all dyspeptics it is necessary to establish a dominating influence. We must command their confidence before much good can be done. The mental state must be improved by occupation which may prevent needless apprehensions concerning health and life. A change of scene is usually beneficial.

—Billings.

Croup.—In desperate cases give as inhalation, every fifteen to twenty minutes:

℞. Ether..... gram. 4
Ether acetic..... " 2
Menthol..... centig. 0.60

—Betz.

Heart Disease.—Atropine is indicated in irritation of the pneumogastric, slow pulse, dizziness, convulsions, syncope. Hypodermic injection one-half to two milligrammes.—Cardarelli.

Ascites from Cirrhosis.—

℞. Resinæ copaibæ ..... ʒ iij.
Spiritus rectificati..... ʒ j.
Mucilaginis acaciæ ..... ℥ ij.
Aquæ..... ad ℥ xij.

M. Misce et fiat mistura.

A tablespoonful to be taken three times a day.

—*The Practitioner.*

Singultus, when persistent and other remedies having failed, wash out the stomach.—Gallaut.

Hay Fever.—The ears are usually pale. Rub them until red and hot.—Ferber.

Consumption.—Creosote has no action on tubercle bacillus, while destroying lower organisms. Its virtue in phthisis is chiefly upon nutrition.—Whitaker.

Tapeworm.—Chloroform greatly increases the efficacy of male fern. Fifty drops may be given.—Duhomeau.

Damiana is effective in the habitual constipation of neurotic subjects, being analogous to strychnia. It acts as a sedative in abnormal sexual appetite, rather than as a stimulant.—*Cleveland Medical Journal.*

Diphtheria.—During the last two or three years I have uniformly prescribed, for spraying the fauces hourly or every two hours, the following:

℞. Squibb's peroxide of hydrogen..... ʒ ij.
Sodii bicarbon..... grains x.
Aquæ destil..... ʒ ij.

One teaspoonful of each to be mixed in the bottle of the hand atomizer, immediately before its use. The nostrils may be sprayed with the same, with the addition perhaps of two teaspoonfuls of water.

—Smith.

Methyl Chloride as a spray upon the surface, cured ten and improved three out of fifteen cases of sciatica.—Hertmann.

Hyoscyamine will be found useful in chorea which has resisted other remedies.—Da Costa.

Chlorosis.—Neutral acetate of copper, one centigram dose.—Liégeois.

Creosotal.—The more creosote one can tolerate, the better its effect. Since creosote can be borne better in no other form than that of creosote carbonate, this is the ideal preparation for phthisical patients.—Sommerbrodt.

Sciatica.—Rest in bed, flannel bandage, splint from axilla to ankle, and at end of treatment careful massage.—Weir Mitchell.

Dysmenorrhœa.—

℞. Liquoris ammonii acetatis fort.... ♏ xl. ad ʒ j.
Tincturæ belladonnæ ..... ♏ x.
Tincturæ cardamomi compositæ... ♏ xxx.
Phenazoni..... gr. x.
Aquæ chloroformi .....ad ʒ j.
Misce et fiat mistura. To be taken every four hours.

Indian Hemp acts almost like a specific in the insanity of women. It is also of value in mania, melancholia, gastric ulcer, and gastrodynia.—Suckling.

Salicylate of Lithia is more efficacious than salicylate of soda in acute and progressive subacute articular rheumatism.—Vulpian.

Appendicitis.—If the patient improves, wait. If the pulse grows worse, if the temperature rises, if pain increases, if tumefaction becomes larger, if tenderness becomes more marked, operate. At no time give morphine, but consider an increase of pain sufficient to demand relief by opium an imperative, unequivocal, and emphatic indication for surgical interference.—Link.

Painful Dentition.—

℞. Muriate of cocaine ..... gr. jss.
Tincture of conium,
Syrup.....āā ʒ ij.
Rub on the gums several times daily.

Rheumatic Iritis.—

℞. Tinct. colchici..... gram. 10
Syr. simp..... " 30
Alc. at 45°..... " 5
Aq. dest. ..... " 120
One or two soupspoonfuls each night.

—Dehenne.

Erysipelas of the Bladder.—Several days after bladder symptoms erysipelas appeared upon the surface. Cystoscopy showed intense redness, cyanotic areas, and raised folds. Streptococci found in urine, cultivated and injected in lower animals, caused manifestations of erysipelas. Injected into the bladder, it produced purulent cystitis.—Fritsch.

Favus.—Remove crusts with poultice and green soap, and apply fifteen grains of bichromate of potassium in an ounce of lard, after hair is cut short.—*Journal de Médecine.*

Enlarged Prostate.—Give five to ten grain doses of muriate of ammonia three times a day.

℞. Ammonii chloridi..... ʒ ss.
Syrup aurantii cort..... ʒ iv.
M. Sig.: A teaspoonful in half a glass of water, t.i.d.

You will be surprised at the results obtained if you will continue the treatment as long as three months.—Terry.

Chronic Urethritis with bluish epithelial plaques in the canal. Decoction of whortleberry (1 to 3) as an injection.—Grünfeld.

Anthrax.—Apply ammonia externally, give some salt of ammonia internally, and, if general infection threatens, make intravenous injections.—Avendano.

Epididymitis treated without restriction of exercise. A flannel bandage, three metres long and three centimetres wide, is used, the first turn being applied above the testicle. This end of the bandage the patient holds until the following circular turns are firm enough to hold it and prevent the testicle from slipping up toward the inguinal canal. The dressing is then completed by alternate circular and spiral turns of the bandage, and the two ends fastened together with a safety-pin, and the whole surrounded with a suspensory bandage. This dressing may be reapplied daily.—Philippson.

Tumors in the Bladder are now known to be of more frequent occurrence than was formerly supposed. 1. The history of hæmaturia and its character may be strongly indicative of the presence of a tumor. 2. Positive evidence of the presence of tumor by the detection of portions of tumor or characteristic cells is seldom got from the urine. 3. Cystoscopic examination, although not always possible, in the majority of instances enables us to detect the tumor when present. 4. With the cystoscope we are enabled to tell the site, size, and superficial attachment of the tumor, and approximately its character. 5. No evil results attend the use of the cystoscope. 6. Tumors in many cases can be thoroughly removed from the bladder. 7. Suprapubic cystotomy gives the best access to the bladder. 8. The proportion of malignant tumors as compared with innocent is very high. 9. Sufficiently good results follow the removal of malignant tumors to justify operation.—Wallace.

Tricophytosis.—

℞. Powdered rhubarb ..... gram. 1
Vaseline..... " 10
Apply every second day.

—Bertrand.

Hemorrhage after Suprapubic Prostatectomy when other Means have Failed.—Plug with an antiseptic graduated tampon the prostate and prostatic urethra, by traction either through the urethra or through a perineal incision; the tampon is provided with a central silk thread for traction, and with four threads at the corners for its removal when desired.—Keyes.

Pustular Eczema of the subacute variety is well treated by means of frequently repeated wet packs of a weak creolin solution (ʒ j. to ʒ viij. water).—Patteson.

Systemic Urinary Infection may be either ascending or descending, and is micro-organic; in the ascending, the infection is by continuity of structures, the ureters and pelvis of the kidney being involved, while abscesses are found in the pyramidal substance; in the descending, the infection is embolic, and due to the presence of the pyogenic urinary microbes in the blood, the only lesions being the multiple miliary abscesses in the cortical substance, due to emboli, the pyramids and pelvis of the kidney as well as the ureters remaining intact.—Halle.

Acne.—

℞. Washed precipitated sulphur,
Pure glycerin,
Carbonate of potassium,
Hydrolate of cherry-bark,
Alcohol.....āā gram. 10.00

—Kaposi.

A Nervous Bladder is one of the earliest symptoms of a nervous brain; for nervousness means a deficient control of the higher nerve-centres over the lower ones; the vesical irritability indicates a lack of brain-control.—Goodell.

Cold full baths are recommended by Mollière in the treatment of severe hepatic colic, the temperature of the bath ranging from 71° to 82° F.

Uric-acid Gravel.—As regards diet, some recommend that the subjects of uric-acid gravel should avoid sugar, fat, and fruit. The most reliable investigations indicate that fat, sugar, and starchy matters have not the slightest direct influence on the production and excretion of uric acid. The only point which is really clear is that the excretion of uric acid is diminished by lessening the albuminoid ingredients of the food, and that it is heightened by increasing these ingredients.—Roberts.

Traumatism of Urethra.—The day will undoubtedly come when every rupture of the urethra will be treated—not by the sound *à demeure* and expectantly, but at

once—by perineal incision and immediate suture. This should always be done when possible. In the perineal urethra this is the operation of choice.—Legueu and Cestau.

Tenesmus and frequent micturition which may be excited by lesions of the ureters, and such tenesmus may, for a certain time, be the most salient symptom of a renal calculus.—Kelly.

Ozæna.—After irrigation with carbolized water, insufflate with

Salol	gram. 5
Acid boric	" 3
Acid salicylic	centig. 0.50
Acid thymic	" 0.20
Talcum powder	gram. 8

Castration for hypertrophied prostate, on the theory that bilateral castration causes atrophy of the prostate, experimentally proven on dogs, has been successfully applied to two old men.—Rocum (*Centralb. f. Chir.*, No. 35, 1893).

Catarrhal Urethritis in small boys was found in sixteen instances out of sixteen cases examined to be of gonorrhœal origin. Direct or indirect infection was made out in several of the cases. In an infant of fifteen months a classical gonorrhœal epididymitis followed.—Rona.

Calcareous Pyelitis.—1. In a calculous patient, or in a patient with a distinct attack of renal colic, suppression of urine should be regarded as directly due to the stone, and in the majority of cases both kidneys will be found to be disabled, for the cessation of the functions of a healthy kidney due to irritation of a stone in the opposite ureter must be very rare. 2. These cases should be treated by operation as soon as it has been found that the function of the kidney has come to a standstill, as there is little chance of a stone being pushed along the ureter when the kidney is no longer excreting urine behind it. 3. In the absence of any evidence as to the location of the calculus, the first step in such an operation should be a median laparotomy, with the hope of discovering the whereabouts of the stone in order to proceed intelligently for its removal. 4. If, by this examination, no calculus can be found, so that further operative procedure cannot be decided upon, massage of the pelves of the kidneys and of the ureters from above downwards should be practised in the hope of dislodging or breaking up a small calculus, if such exists.—Cabot.

Tuberculosis of Prostate.—One-third of the cases develop insidiously. The bladder, seminal vesicles, and testicles are usually involved. Treatment, intra-vesical injection of iodoform, perineal incision of abscesses.—Marmedel.

Tuberculous Testicle.—Castration is a bad operation, as it does not prevent relapse. In eighty cases out of one hundred, where castration is practised, the prostate and the seminal vesicles are already the seat of tubercle.—Verneuil.

The Nephritis and Albumin in the urine after vaginal hysterectomy is due to the wounding of the hypozotic plexus and ovarian plexus, and the irritation is reflected into the renal plexus, disturbing the kidney. The shock from abdominal and vaginal section is due to the damage inflicted on the sympathetic plexus, and is often manifest in kidney disturbance.—Robinson.

Tertiary Syphilitic Manifestations may be due to direct inoculation without the necessity of a primary or secondary stage.—Klotz.

Bulbo-urethral Adenitis—phlegmasia of a bulbo-urethral gland—is ordinarily the outcome of urethritis, but may also arise in consequence of a blow upon the perineum, or of an injury of the gland's duct by the accidental penetration of a capillary bougie. The left seems to be more commonly attacked than the right, and very exceptionally are both glands affected.—Gouley.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

SIR ANDREW CLARK.

London, November 7, 1893.

Sir Andrew Clark died yesterday afternoon, to the profound regret of innumerable friends. He had begun his sixty-eighth year, his sixty-seventh birthday having been on October 28th. He was seized, as already reported, with paralysis and aphasia on October 19th, during his morning work. The case excited the gravest apprehensions, as he was for some time unconscious and Cheyne-Stokes respiration was noticed. This, however, passed away and he partially recovered his power of speech. It was then hoped that he might recover, at any rate for a time, and on Thursday and Friday morning inquirers were told that his medical friends considered he was in no immediate danger. But on the same Friday he became worse and gradually sank. Yesterday morning, although conscious, he was evidently sinking fast. Soon after noon it was obvious he would not last the day, and about four o'clock his family were assembled. He was then unconscious, and he passed peacefully away about half-past four.

Sir Andrew will be greatly missed; he had become a prominent figure to the public, and had filled with honor the highest posts in his profession. As president of the Royal College of Physicians, he was a great success. He had presided also over several of the medical societies, and in all offices had given the greatest satisfaction. His urbanity, his readiness of speech, his knowledge of men, and his large stores of professional and general information well qualified him for the position he held in our esteem and well earned our admiration. He has had an eminently successful career, but has not been spoiled by his success, which has enabled him to gratify his natural generosity. Kind, courteous, sympathetic, full of goodwill to his brethren, he has always been accessible to them and happy in placing his skill at their service when they were themselves ill. There is sorrow to-day in many such households at the loss of a valued friend and counsellor.

Sir Andrew Clark was a true, sturdy, and canny Scot, born in Aberdeen and a graduate of Marischall College. In student days he had symptoms of tuberculosis, and on qualifying he entered the naval medical service. In this service he became pathologist to Haslar Hospital. He resigned the service in 1854 to take the pathological post at the London Hospital, then a very minor position with a moderate honorarium; but this became his stepping-stone to the staff. He was elected assistant physician at the first vacancy, and thenceforward passed regularly on as successive vacancies occurred, and after his full term of active work was made consulting physician. The great work of his life was done in the wards of the London Hospital, and he was always ready to say that he owed everything to that great institution. In his earlier years there he was again attacked with symptoms of consumption, but they subsided and he continued his career with unabated energy. Of late years he would recommend men who could manage to keep at work to do so, and sometimes tell them as an encouragement how nearly he had at one time been obliged to give up, and instance his case as a proof that incessant activity is not detrimental. Possibly, of late years he may have done more than was desirable, for he was about the busiest physician in London, and some are suggesting that his case is a lesson on overwork. I doubt that, however, so far as practice is concerned. But official and social claims were probably detrimental. He felt that himself, and when, more than a year ago, after a sharp illness, I suggested that he should withdraw from some of these, he told me he knew that the dinners he was obliged to attend were most injurious. Still, his sense of the obliga-

tion to discharge the smallest duty or to act on the custom of an official position was so strong, that he would omit nothing that could be considered proper or usual. He was also, as to official punctuality, most exact, although the exigencies of such a large practice often compelled him to be late at consultations. In illustration of this, he was present at a lecture at the College of Physicians the day before his illness began, and on that occasion he was late in arriving for the first time in the six years in which he has been president.

Sir Andrew Clark did not contribute much to the literature of his profession. In early days he wrote the chapter on the Anatomy of the Lungs for Dr. Herbert Davies's work on the "Heart and Lungs." He contributed to the first volume of the Clinical Society's "Transactions" a paper on "Fibroid Phthisis," and other papers to various periodicals. Reports of some of his lectures have also been printed. But it was as a speaker and a clinical observer that he shone. He was rather a great talker than a writer, for years so busy that he could not supervise the publication of his lectures. Otherwise some of them would have perpetuated his striking ability.

The baronetcy was conferred in 1883 on the recommendation of Mr. Gladstone, who had, as is well known, for many years been a patient of the deceased. Sir Andrew was twice married, and leaves a son and two daughters with the widow to lament his loss. The baronetcy passes to the son, a member of our profession, James Richardson Andrew Clark, Surgeon-Major Army Medical Staff, F.R.C.S., Edin., now in his forty-second year.

New Instruments.

A COMBINED LACHRYMAL GOUGE.[1]

By H. DAVISON SCHWARZSCHILD, M.D.,

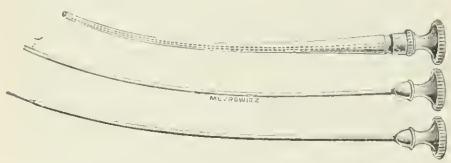
ASSISTANT SURGEON MANHATTAN EYE AND EAR HOSPITAL, ETC., NEW YORK.

This new instrument, a description of which follows, is applicable to those diseases of the lachrymal apparatus that have not proved amenable to the use of sounds or similar forms of treatment.

It is not an uncommon occurrence to encounter a stricture of the nasal duct which does not permit the most slender probe to pass, and is not incisable with any of the canaliculus knives. Such a state of affairs indicates the presence of an exostosis more or less diffuse. At other times a shelf like osseous projection may be located, which impedes the escape of tears and partially obstructs the canal.

These abnormalities require the use of a gouge for their removal.

Purulent and muco-purulent discharges are frequently occasioned by a partial necrosis of the walls of the nasal duct, and are most successfully treated by chiselling away the necrotic foci, and applying antiseptic applications with a porte caustique.



The apparatus consists of four separate parts: Cannula, director, gouge, and porte-caustique.

The first is made of German silver, and through it the others may be passed. When the director is inserted it corresponds to a Bowman sound No. 10.

The gouge is constructed of steel, the shank strong, although flexible, and cutting edge highly tempered; the latter grooved portion reaches ad maximum 7 mm. from the end of the cannula, and the chiselling may be performed in any arc, by rotating the handle of the instrument.

A light mallet, such as we employ in mastoid operations, may be used in connection with the gouge.

The spiculæ of bone removed, if large, are withdrawn with a McKay forceps; if fragmentary, can be washed through the inferior meatus into the nasal fossa.

The porte-caustique is made of silver, with a corrugated tip tapering to a point, and protrudes 6½ mm. from the inferior opening of the cannula. To this point may be fused the desired chemical, or a small piece of absorbent cotton may be wound around it, for saturation with a cocaine solution or any other fluid selected. Before using the instrument for this purpose it must be withdrawn into the cannula far enough to protect the application until the desired point is reached.

The author is indebted to Mr. E. B. Meyrowitz for the highly satisfactory manner in which he has had the above-described instrument constructed.

30 West Thirty-fifth Street.

[1] Exhibited before the Academy of Medicine, Ophthalmological Section, June 19, 1893.

AN ENUCLEATION HOOK—A CATARACT HOOK—A SET OF NEEDLE CANALICULUS PROBES.

By JOHN DUNN, M.D.,

RICHMOND, VA.

The larger of the above double hooks is used in enucleation, after section of the muscles, to grasp the ball posterior to the insertion of the internal rectus, and to pull the ball outward and forward while section of the nerve is made. It differs from the usual hook for this purpose in being stronger and in the curve of the hooks.

The smaller double hook is used in the extraction of the lens when dislocated. It is a double-pointed Stevens hook. The shank is flexible.

The lower cut represents a set of canaliculus probes. The smallest probe has a diameter of ½ mm. throughout; the medium-sized probe has a rounded point ½ mm., and increases gradually to ¾ mm. at its centre; the largest probe is ½ mm. at its points, 1 mm. at the centre.

These needle probes are of value whenever, for any reason, there is need to know whether the canaliculi are free; when there is need to dilate these little canals; and when it becomes necessary to dilate the puncture in order to admit the point of a syringe to wash out the lachrymal sac. It is well to begin with a medium-sized probe. These probes are not flexible, and are made simply for use in the canaliculi, where, in my hands, they have proved more serviceable than any probe with which I am acquainted.

The above instruments were made for me by Messrs. Bartlett, Garvens & Co., of Richmond, Va.

Hospitals for Consumptives.—A society has recently been established in Saxony, the object of which is to erect hospitals throughout the kingdom for the treatment of phthisical patients. The Association is under the protectorate of King Albrecht; the presidents are Professors Curschmann, of Leipzig, and Fiedler, of Dresden.

The Old Story.—A correspondent of an English contemporary, writing from a small manufacturing town, says that the number of practitioners has risen there within four years from four to eight. The population in the meantime had not increased. As an evidence of how the doctors were prospering, three children of one of them were working in the factory.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 18, 1893.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	22	11
Scarlet fever	78	3
Cerebro-spinal meningitis	0	3
Measles	182	11
Diphtheria	198	58
Small-pox	10	1
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Absolute Alcohol for Scientific Purposes is Duty Free.—The decision of the United States Circuit Court, S. D. New York, *in re* Kny, rendered June 27, 1893, is just reported in 57 Federal Reporter, p. 190, affirming the decision of the board of general appraisers, which reversed the classification of the collector of the port of New York on certain so-called "absolute alcohol." The latter classified it as "alcohol, 198 degrees, $4.95," at $2.50 per proof gallon, under the provisions of paragraphs 329 and 333 of Schedule H of the tariff act of October 1, 1890. Against this classification the importers protested, claiming that the article was a scientific preparation for college use, and duty free, under paragraph 677 of the free list of said tariff act. This "absolute alcohol" was made by chemical action by adding lime, and then distilling the liquid over again, by means of which the high percentage of 99.5 of alcohol was obtained, and was from two to three times higher in price than the regular alcohol of commerce, running only to 95 per cent. That it was "not intended for sale," within the meaning of said paragraph 677, was to be understood that it was not intended to be disposed of by sale to any other person than the corporation or society for whose special use the importation was permitted to be made, though in this case it was admitted that the importers' profit in furnishing the article to the colleges in question was about twenty per cent.—*Journal of American Medical Association.*

The Bacteriological Craze.—This is the age of germ rabies, and stark madness has overtaken the hygienists and the public with reference to bacteric infection. Every ounce of water we drink and every cubic foot of air we breathe is supposed to be scientifically assayed, and if more bacteria than the approved minimum are found, we are threatened with terrible consequences. The joke of the matter is that the people who are the victims of the craze do not seem to be able to see farther than their noses. They are in agonies of apprehension lest their milkman may have diluted his liquor with bacteria laden water, and they excessively excite themselves if the cubic contents of their sleeping-rooms is below the scientific minimum; but they pay no regard to the fact that, from morning to night, they are imbibing monstrous doses of bacteria through other media. They never think of the danger of carrying about their person a banknote which has been bosomed for unlimited time by a reeking fishwoman or costermonger—they box themselves up in a theatre or concert-room packed with inconceivable myriads of germs of all sorts of diseases—they suck grapes which have passed through an endless series of dirty hands, and they smoke cigars which have been lately grasped between the lips and fastened with the spittle of, perhaps, a phthisical tobacco worker. Lastly, they will cool their glass of champagne at the most *distingué* dinner-party with the ice recently frozen off a ditch which is little better than a cloaca, and they trouble not themselves about its bacteric befoulments. We notice we are moved to these observations by the fact that this latter point has been taken up by the Parisian hygeists, and that laws are being made to control the sale of dirty ice. It has been clearly established that much of the ice used in the most aristocratic cafés and clubs is taken off ponds impregnated with every describable abomination, and that when this ice is melted, myriads of bacteria of every form of virulence are found in a state of activity. We are not to be understood to discourage precaution against the use of foul water or foul air. It is well to be clean, even though we cannot be of spotless purity, but there is no doubt that the bacteric hobby is, at present, being ridden to death, and that any of us who survive for another twenty years will then laugh heartily at the fashionable craze of to-day, just as we now laugh at the iridectomy mania, Koch's tuberculine, or any of the equally *de rigueur* crazes of the past twenty years.—*Medical Press.*

The Treatment of Gout.—Mordhorst (*Therap. Monatch.*, August, 1893) believes that renal uric acid calculi can be dissolved by drinking abundantly even weak alkaline waters, and as the result of frequent experiments he has found that even faintly acid urine will reduce the size of these calculi. In view of these facts, which are more or less generally acknowledged, he asks why, even after a prolonged use of alkaline waters, the deposits in the tissues do not diminish, and the symptoms do not abate? Some years ago the author, thinking that the urine alone (and not the tissues) was rendered alkaline, examined the sweat, finding it always faintly acid or neutral under these circumstances. Freudberg made frequent experiments with the blood, finding it very difficult to influence its reaction, a large amount of the acid introduced appearing to be lost in the body. As uric acid and its salts can be deposited only from acid fluids which must exist in the skin, connective tissue of muscles, nerves, etc., it can be explained why alkaline waters have been unable to produce any effect. He therefore began to administer to his gouty patients sufficient alkaline water, namely, three bottles daily, to render the urine very alkaline and the sweat neutral or alkaline. The result was most satisfactory, tenderness diminishing, and the nodes becoming perceptibly smaller. The alkalinity of the urine was so great that ten to twelve per cent. of half-normal sulphuric acid were required to make it neutral, the urine at the same time being quite clear, and remaining thus for several days. As regards the different natural waters, this result was achieved only with Wiesbaden gout water, the chalk in other waters causing considerable turbidity of the urine. Another feature observed was the progressive diminution in the uric acid excreted. The author, who is himself subject to gout, confirmed these results in his own person, and adds that the water cure should, when possible, be supplemented by a suitable diet, warm mineral baths with subsequent perspiration in bed, and that one to two bottles of the above named Wiesbaden water should be taken daily.

A Poor Man's Dietary and its Chemical Equivalent.—Mrs. Ernest Hart writes in *The Hospital:* Very much has been written about dietaries, and the amount of food necessary to raise so many food-tons, in other words, to enable a navvy or docker to do his daily tasks, but no one except Mrs. Barnett, has, so far as I know, taken the trouble to turn the percentages and quantities of carbonaceous and nitrogenous food required to maintain health, into economical dishes of potatoes and meat for a family of a working man and his wife and eight children and to show us the cost of living to a farthing. Assuming that, on the lowest estimates, a working man requires 16 ounces of carbonaceous and 4 ounces of nitrogenous food a day; his wife 12 ounces of carbonaceous and 3 ounces of nitrogenous food: and his eight children an average of 8 ounces of carbonaceous, and two ounces of nitrogenous

food a day each; the total indicates that 92 ounces of carbonaceous and 23 ounces of nitrogenous food have to be daily provided. To show how this can be done with all the advantages of scientific culinary knowledge, Mrs. Barnett gives the following daily *menus* which I make no excuse for quoting at length:

Breakfast—Oatmeal Porridge.

Quantity of Food.	Cost. s.	Cost. d.	Carbonaceous. oz.	Nitrogenous. oz.
1½ pound of oatmeal	0	2½	14	3
1½ pint tinned milk	0	1½	2¼	1
½ pound treacle	0	1½	7	—

Dinner—Irish Stew.

1½ pound meat	0	8	3½	3½
4 pounds potatoes	0	2½	14	2
1½ pound onions	0	1	5¼	2
A few carrots	0	1	¼	—
½ pound rice	0	1	7	½
1½ pound bread	0	2¼	13½	2¼

Tea—Bread and Coffee.

2½ pounds bread	0	3¾	22½	3¾
2½ ounces coffee	0	2½	½	¼
1½ pint tinned milk	0	1½	2¼	1
Total	2	5	92	18½

Here there is a short allowance of nitrogenous food, which would be corrected by a rather larger allowance of bread. I will give another of these thoughtful daily *menus*:

Breakfast—Bread and Cocoa.

Quantity of Food.	Cost. s.	Cost. d.	Carbonaceous. oz.	Nitrogenous. oz.
2½ pounds of bread	0	3¾	22½	3¾
1½ ounce cocoa	0	1½	¾	¼
1 pint tinned milk	0	1	1¼	½
2 ounces sugar	0	½	1½	—

Dinner—Lentil Soup and Toasted Cheese.

1½ pound lentils	0	3	15	6
1 pound cheese	0	8	4½	5½
1½ pound bread	0	2¼	13½	2¼

Tea—Rice Pudding and Bread.

¾ pound rice	0	1½	10½	¾
½ pint tinned milk	0	1½	2¼	1
2 ounces sugar	0	½	1½	—
1½ pound bread	0	2¼	13½	2¼
Total	2	1¾	86½	22¼

A Suffering Patient with a Statistical Bent.—A physician of this city sends us the following unique report from a former patient, who had been turned over to the care of a New York surgeon for operative treatment of tuberculous glands of the neck.

"*Account of Myself up to October 29, 1893.*—Operated on May 10th, October 16th, 1890, and April 1, 1891. Have had 87 enlargements up to now and 66 suppurating openings. Have now 27 openings suppurating—6 in neck and throat, 6 in chest, 7 in back between waist and shoulder blade, 2 in thumb-joint, 1 in right armpit, 3 in left armpit, 1 in left side five inches below armpit, 1 in right side five inches below armpit. No less than 160 quarts of pus has come from me. Have used no less than 6,000 yards bandages, 15 yards of court plaster, 2 yards of oil-silk, 100 pounds of flaxseed, 20 pounds of absorbent cotton, 6 pounds of vaseline, 1 pound of salve, 1 pound of oakum, 2 pounds of licorice powder and salts, 1 ounce of aristol, 4 ounces of iodoform, 600 pills, mostly sulphide calcium, 10 plasters, 1 caustic pencil, 70 quarts inward medicine, 2 quarts peroxide hydrogen, 2 quarts carbolic acid, 12 quarts liquor, 1 pint iodine, ½ pint balsam Peru, 4 syringes. This does not reach the figure at all. Yet it is enough to convince the most morbid. I hope to get well yet. Yours, etc."

Physicians in Japan.—An ex-attaché writes: "Perhaps the most charming manner of compensating physicians for their care and attention is that which is customary among the natives of Japan. Physicians do not charge for their services, but, on the contrary, decline to name an amount, and protest against any idea of remuneration. Patients on their side are too proud to accept such services free, and send to the physician, not as a fee but more as a friendly gift or token of gratitude, a sum of money proportionate to the means of the giver, with some piece of silk, bronze, or lacquer work—the idea being that medical attendance is by far of too important and elevated a character to be desecrated by barter for filthy lucre." "What a pity," *The Medical Age* adds, "that our boasted Western civilization, with all its commonplace vulgarity and lack of delicacy, will not admit of adoption of such a charming method of intercourse between the medical man and his patients!" And yet a check is after all better than bric-à-brac. We are not disposed to quarrel with the methods of the West, though the bronze jugs of Japan are beautiful.

Ancient Cerebral Localization.—A plausible case was made out some time ago (by Professor Anagnostakis, of Athens, if we remember aright) for Homer as the first exponent of the antiseptic treatment of wounds; the germ of the medicinal treatment of drunkenness is to be found in Pliny; and microbes have been "in the air"—metaphorically as well as literally—for centuries. If there was one thing, however, that we had fondly imagined latter-day workers might claim as all their own without the shadow of a doubt as to the goodness of their title, it was the localization of function in the brain. Now M. Farabeuf, the distinguished Professor of Anatomy in Paris, has unearthed a work by Joseph Baader, who, it appears, was a Professor at Freiburg-im-Bresgau from 1746 to 1750, in which the possibility of localizing the sensory and motor functions of the brain is clearly indicated. The work, which is entitled *Observationes Medicæ Incisionibus Cadaverum Anatomicis Illustratæ*, was published separately in 1762, and was afterward reprinted in E. Sandifort's *Thesaurus Dissertationum* (vol. iii.) in 1778.—*British Medical Journal.*

A Decade of New Remedies.—"There are at least one hundred new remedies of synthetic origin now in general use that were not known ten years ago." So an American contemporary says; but we doubt if anyone can compile a list of one hundred. Who will try?—*Chemist and Druggist* (London), September 30, 1893.

"We are not responsible for the original statement; but the invitation is general, and we are anxious that our English friend should have a prompt response from America, so here goes," says the editor of *Notes on New Remedies:* "Acetanilid, agathin, alpha-oxynaphthoic acid, alumnol, amylenhydrate, analgen, antipyrine, antiseptol, antispasmin, antithermin, aristol, asaprol, asepsin, benzanilid, benzonaphthol, benzosol, betol, bromal-hydrate, bromoform, bromol, chinoline, chloralamid, chloral-ammonium, chloralose, chlorphenol, creolin, cresalol, cresin, cresol, cresol-iodide, cresotic acid, diuretin, dulcin, ethyl bromide, ethyl chloride, eugenol, eugenol-acetamid, euphorin, europhen, exalgine, formalin, formanilid, gallacetophenone, gallo-bromol, gallol, guaiacol, guaiacol-carbonate, homatropine, hydracetine, hydroquinone, hypnal, hypnone, ichthyol, iodol, iodopyrine, kairin, losophan, lysol, metaldehyde, methacetine, methylal, methyl chloride, methylene-blue, methylene chloride, methyl-violet, microcidine, naphthalene, naphthol, naphtopyrin, orexine, oxychinaseptol, paraldehyde, pental, phenacetine, phenetol, phenocoll, piperazine, pyridine, resorcin, resorcinol, saccharin, salacetol, salicylamide, saliphen, salipyrin, salocoll, salol, salophen, saprol, solutol, solveol, sozal, sozoiodol, styracol, sulphaldehyde, sulphaminol, sulphonal, tetronal, thalline, thermifugin, thilanin, thioform, thiol, thiophen, thioresorcin, thiosinamin, thymacetin, tolypyrin, tolysal, tribromphenol, trional, tumenol, uralium, urethane."

The French Society of Dermatology and Syphilography will hold its next annual meeting at Lyons, in August, 1894.

THE QUESTION OF THE COMMUNICABILITY OF LEPROSY.

By BEAVEN RAKE, M.D.,

LONDON, ENGLAND,

MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPER ASYLUM; LATE MEMBER OF THE INDIAN LEPROSY COMMISSION.

From the earliest times leprosy has been regarded as communicable from one person to another. Under the Mosaic dispensation, and in Europe in the middle ages, there were stringent regulations providing for the segregation of those suffering from the disease.

This ancient opinion as to the communicability or contagiousness of leprosy, has not entirely held its ground in this century, and I purpose briefly to discuss some of the modern evidence for and against the theory of contagion.

The subject may be conveniently considered under the following six heads:

1. Bacteriological evidence.
2. Inoculations of animals.
3. Inoculations in the human subject.
4. Vaccination.
5. Practical experience.
6. Alleged increase of leprosy.

1. **Bacteriological Evidence.**—To Hansen, of Bergen, is due the epoch-making discovery of the leprosy bacillus and the inauguration of a new and scientific study of the disease. He first advocated the parasitic theory in 1869. For some years, however, he was in much doubt on the subject, and it was not until 1880[1] that he definitely announced the discovery of a specific bacillus in leprosy. Neisser,[2] in the autumn and winter of the same year, working at the San Lazaro Leper Hospital at Granada, Spain, confirmed Hansen's results, and applied the aniline-color tests which have since been recognized as distinguishing the bacilli of leprosy and tubercle from those of other diseases.

Neisser found bacilli in the cutaneous modules, the mucous membrane of the mouth, palate, and larynx, the connective tissue of the peripheral nerves, in cartilage and in the cornea, lymphatic glands, spleen, liver, and testicle.

Hansen's discovery has since been confirmed by observers in all parts of the world, and it may now be affirmed that the leprosy bacillus is present in some part or parts of the body of every leper, at some period or other, in the course of the disease.

It may now be well to briefly examine the results which have attended the attempted cultivation of the bacillus lepræ.

Hansen[3] kept specimens of leprous blood in a moist chamber and obtained a mycelial growth, which at that time he called a leprosy culture. It is, however, probable that this growth was due to fouling, and Hansen has abandoned his view.

Neisser, when working at Granada, removed an unbroken tubercle with every precaution, and finely divided it with needles sterilized in a flame. With fragments of this tubercle he inoculated blood serum. He also kept pus and juice from leprous nodules in sealed capillary tubes. As a result of these experiments, he describes three different bacilli. As, however, he failed to cultivate any of them in generations, it is impossible to be certain that he got true cultures.

Arning[1] allowed pieces of leprous tissue to macerate and decay for several months in water at ordinary temperatures, and described growths of the leprosy bacillus, but he did not regard these as true cultures. At the Trinidad Leper Asylum,[2] I made a series of cultivation experiments extending over almost three years. As nutrient media I used blood serum, ascitic fluid, hydrocele fluid, all from the bodies of lepers, and various combinations of agar and gelatine with these. Pieces of cutaneous leprous nodules, of lymphatic glands, and of nerve were used for inoculation, also fragments of the viscera of lepers, and vaccine lymph. Numerous growths of staphylococci of various kinds were obtained, but no cultures of leprosy bacilli. Inoculations of animals with the growths were negative. Results obtained by allowing pieces of tubercle to putrefy in fluids were equally negative, nor did I observe the abundance of leprosy bacilli described by Arning in earth in which lepers had been buried. To test this point I buried leprous hands and other specimens, and dug them up at varying intervals. Examinations of the surrounding earth failed to show any specific bacilli.

In 1887, Bordoni-Uffreduzzi,[3] of Turin, announced the cultivation of the bacillus lepræ. Having failed, like other experimenters, to grow the bacillus from pieces of leprous nodules implanted on solid media, he regarded the bacilli in these nodules as enclosed in cells and probably dead. He therefore examined other tissues, and in the bone-marrow of a dead leper he found free bacilli. He inoculated tubes of peptone-glycerine serum with fragments of this bone marrow, and obtained cultures of a small bacillus frequently bulbous at the ends, and resembling in form and size the bacillus of the tissues. It, however, took the fuchsin stain with far more difficulty than the latter bacillus.

When passing through Turin in 1891, I called on Professor Bordoni-Uffreduzzi, who kindly showed me coverglass preparations from his original culture, and gave me a secondary growth. I took this tube to London with all possible care, and raised sub-cultures from it in Dr. Slater's laboratory, which he was kind enough to place at my disposal. I fear, however, that some contamination must have taken place, for the sub-cultures which I raised differed entirely from that originally figured by Uffreduzzi. It may be stated here that the Italian professor made a large number of inoculation-experiments on animals, but wholly failed to establish the pathogenic nature of his cultivation.

Gianturco,[4] of Naples, has obtained a cultivation which Uffreduzzi considers identical with his own. More recently Campana,[5] of Genoa, has described a third bacillus as cultivated from leprous material. I have seen specimens from these two cultures, but could not feel convinced that they were leprosy bacilli.

A series of culture-experiments was carried out at Almora and Simla,[6] by Dr. Buckmaster, Surgeon-Major Thomson, and myself, according to a method suggested by Dr. Buckmaster. Blisters were raised over cutaneous leprous nodules, and at the same time over areas of nor-

mal skin, on lepers. Sterilized capillary vaccine-tubes were then charged with a minute quantity of the fluid from blister over tubercle, and with seven or eight times as much fluid from blister over normal skin. They were then sealed in a flame. In order to secure a constant temperature the tubes were packed with a small thermometer in a cylindrical box, and carried in the axilla. After incubation for one month, the tubes were opened, examined, and resealed. Several bacilli resembling those of leprosy were seen. A tube containing some of these bacilli was now sterilized as much as was possible without injury to the contents, broken at both ends, dropped into glycerine bouillon, and shaken. On the third day, a slight turbidity appeared, and increased daily. Minute particles collected on the surface, and adhering together, formed a pellicle which gradually extended from the centre to the periphery. From this original bouillon, glycerin-gelatin and glycerin agar were inoculated, and vigorous growths were obtained. Material from two different patients gave similar results. Under the microscope these growths showed thick clusters of bacilli shorter and slightly thicker than those found in leprous nodules, but retaining the pink stain after treatment in warm Ziehl's solution for twenty minutes, and subsequent decolorization in twenty-five per cent. nitric acid. Subcultures from the original growths did not resist the action of the acid so well, though they stained to some extent.

Rabbits, dogs, and a monkey were inoculated with small quantities of these cultures, but the results were entirely negative. We were thus unable to assert positively that the growths obtained were those of the bacillus lepræ, but that the bacillus cultivated by us had several points in common with that in the tissues is undoubted.

Remembering the four postulates which have been laid down by Koch as necessary to show beyond a doubt that a micro-organism is the cause of a disease, and applying them to the case of leprosy, it will be evident, from the various observations and experiments above quoted, that the first postulate is generally admitted as regards the disease under consideration. The second is doubtful, while the third and fourth have never yet been demonstrated.

2. **Inoculations of Animals.**—These may be of two kinds: 1, with cultures; 2, with tubercles or other pieces of leprous tissue.

We cannot logically speak of inoculations of cultures of the bacillus lepræ, for, as was shown in the last section, such a culture has not yet been demonstrated beyond doubt. All we can say is, that cultures of bacilli obtained after inoculation of media with leprous products have always failed to produce leprosy in animals. This was alluded to in the last section.

The other method of inoculation of animals which has been tried, is by means of pieces of leprous nodule or other leprous tissue.

Neisser[1] was one of the first to inoculate animals with leprous material. When working at Granada in 1880, as already mentioned, he experimented on rabbits and dogs. Pieces of freshly extirpated leprous tubercle were introduced into the peritoneal cavity and anterior chamber of the eye in rabbits. The results in them were absolutely negative. Pieces of leprous tubercle were also inserted beneath the skin of dogs. One of the dogs died after a month, and a small nodule was found at the site of inoculation. This contained numerous bacilli. Another dog was killed about three months after inoculation, and a local nodule the size of a bean was found. This contained characteristic leprous cells, but no bacilli. Neisser was of opinion that a local leprosy was thus produced, which, however, did not become general.

Damsch[2] introduced leprous tubercle into the anterior chamber of the eye of rabbits, and described an infiltration of the iris, ciliary body, and Descemet's membrane with cells containing leprosy bacilli. Vossius[3] obtained similar results, but neither of these observers found a distribution of bacilli through the body. Wesener, Leloir and Campana[4] have, however, shown that results identical with those described by Damsch and Vossius are obtained on implanting leprous material hardened for years in alcohol.

Campana[5] inoculated leprous tubercle in the vascular comb and beard of fowls, and often obtained at the site of inoculation a local tumor containing large cells produced in the inflammatory process. These took up leprosy bacilli in the same way as leucocytes take up inorganic foreign bodies.

Köbner[6] and Hansen[7] found negative results in monkeys after inoculation.

Hillairet and Gaucher[8] inoculated a pig with leprous tubercle, but the results were negative. Vidal[9] also performed a similar experiment, and sections of the skin and subcutaneous tissue containing the inserted fragment, showed a year after the inoculation numbers of leprosy bacilli in the implanted mass, but none in the surrounding tissue.

Thier,[10] Kaurin,[9] Arning,[10] and Leloir[11] have hitherto failed to establish leprosy in animals. At the Trinidad Leper Asylum[12] I have made a series of experiments, extending over nearly ten years. Guinea pigs, rabbits, cats, pigs, bats, fowls, small birds, a dog, and a parrot have been inoculated with pieces of cutaneous nodule and other leprous material, with no result, except in the cases presently to be described as capable of another explanation. Besides attempting to inoculate beneath the skin, in the anterior chamber of the eye, and in the peritoneal cavity, I have fed pigs and fowls, during varying periods up to two years, with pieces of leprous cutaneous nodule, and with parts of viscera from the bodies of lepers. Up to the present time I have seen no sign of infection in this way.

The experiments which have attracted most attention of late years are those of Melcher and Ortmann,[13] in Königsberg. They introduced pieces of freshly extirpated leprous tubercle into the anterior chamber of the eye of rabbits, and described four months afterward a visceral and lymphatic gland lepræ. The autopsies showed the cæcum, spleen, lungs, and lymphatic glands to be infiltrated with nodules varying in size from a pin's head to a pea. In these nodules were quantities of bacilli, which they regarded as those of leprosy.

Arning[14] and Raffer, who have examined the specimens of Melcher and Ortmann, are convinced that the Königsberg experimenters have succeeded in inoculating animals with leprosy. Wesener, on the other hand, has carefully gone over the same ground, and critically controlled these experiments, and he concludes that proliferation of the leprosy bacilli does not occur, but merely a diffusion of the bacilli introduced. He and Hüppe[15] believe that Melcher and Ortmann, like many others, have sown leprosy and reaped tuberculosis.

In this connection I may allude to a series of observations which I have lately made at the Trinidad Leper Asylum, some of which have been published.[16]

In a large proportion of the bodies of lepers I have found after death, either, 1, pulmonary phthisis indistinguishable from that occurring in non-lepers, and characterized by small tubercles scattered more or less through-

out the lungs, and often agglomerating, caseating, and breaking down into large cavities at the apices and elsewhere; or, 2, a general diffusion of small gray or yellow tubercles throughout the viscera, and sometimes on the serous membranes.

The latter condition often appears at the autopsy to be of recent date, and from the clinical symptoms, such as fever and wasting, which come on a few weeks before death, it would seem that the appearance of these visceral tubercles coincides with the absorption of cutaneous leprous tubercles which so often precedes death. It would therefore seem that these visceral tubercles are either leprous and due to absorption of leprous products from the skin, or they are tuberculous and due to accidental absorption of tuberculous material, quite apart from the leprosy.

I inoculated five guinea-pigs beneath the nape of the neck, with small pieces of pulmonary tubercle taken from three different lepers. The five guinea-pigs died, or were killed, at periods varying from four to six months after inoculation, and in all of them were found enlargement and caseation of lymphatic glands, and small nodules in the lungs, liver, and spleen, varying in shape and in size, ranging from about one-sixteenth to one-third of an inch in diameter. In the lungs they were translucent, and in the spleen and liver yellow or dark red in color. Microscopical examination showed bacilli indistinguishable from tubercle bacilli. As I have frequently inoculated guinea-pigs with leprous cutaneous nodules, and have always found no changes whatever in the viscera after death, I am led to believe that the above-described visceral nodules are tuberculous in nature, and further, that they are derived from the pulmonary tubercles of lepers. If they were derived from material introduced accidentally during the process of inoculation, we should expect equally to find them following the inoculation of leprous material. This is what Wesener claims for Melcher and Ortmann's inoculations, but in my experiments, as already stated, I have never found such nodules.

The obvious inference, then, is that the visceral tuberculosis so common in lepers is tuberculous, *i.e.*, connected with the bacillus tuberculosis. But if this visceral tuberculosis is due to absorption of cutaneous leprous tubercles, we are faced by a new difficulty, and there are only two solutions:

1. There is absorption of independent tuberculous material, presumably tubercle bacilli, through the open ulcers so common on leprous tubercles.

2. The bacillus leprae and the bacillus tuberculosis are varieties of the same bacillus, as has been suggested by Danielssen.

It is obvious that the question is by no means solved yet, but these recent experiments of mine have an important bearing on Melcher and Ortmann's results and Wesener's criticism.

I may state here that I failed to obtain cultures of the bacillus either of leprosy or of tubercle, from the original nodules in the lungs of the lepers, or from the nodules produced in the viscera of the guinea-pigs after inoculation.

Tedeschi [1] has recently reported an experiment which proves, in his opinion, that leprosy is transferable from man to animals. A monkey was inoculated beneath the spinal dura mater with a piece of leprous nodule. The animal died in eight days, and at the necropsy new tissue was found at the seat of inoculation. Large numbers of bacilli resembling those of leprosy were found here, also in the cerebro spinal fluid. The spleen was swollen and contained similar bacilli. These bacilli would not grow on agar and blood serum, while from the bacilli found after similar inoculations with tubercle, growths were obtained.

This experiment is the only one of its kind, and it will be necessary to repeat it before an opinion can be expressed. Meanwhile the weight of accumulated evidence referred to in this section seems to render probable Besnier's views, that leprosy is an essentially human disease and cannot be transmitted to animals.

[1] Centralbl. für Bakt., August 1, 1893.

3. **Inoculations in the Human Subject.**—Intentional inoculations performed on man have necessarily been few. Like those in animals they may be of two kinds:

1. Inoculations with micro organisms obtained in attempted cultures of leprosy bacilli.

2. Inoculations with pieces of tubercle or other leprous products.

1. *Inoculations of Culture Products.*—Healthy subjects for inoculation not being obtainable, I determined to try the effects of inoculation of culture products in anæsthetic lepers. During the latter half of 1889 I made some cultures on agar and serum and on solidified hydrocele fluid, from a fragment of a cutaneous leprous tubercle, and from a piece of liver from the body of a tuberculated leper. The microscope showed this liver to contain numerous leprosy bacilli. The growth obtained from these tissues showed no leprosy bacilli, but quantities of micrococci. Though these cultures were thus negative in not containing the specific organisms of leprosy, I thought it worth while to try the effect of injecting them, for it was quite possible that they might contain other products not recognizable by the microscope.

I chose twelve anæsthetic lepers and injected solutions of the growths above mentioned beneath the skin in various parts of the body. The immediate result was in most cases local swelling, redness, and tenderness, with more or less temporary rise of temperature. These symptoms usually passed off in a few days. In one or two cases, however, an abscess formed at the site of injection.

The late history of the cases was as follows: Four of the patients died within the next two years of intercurrent disease. No development of tubercles was found in them either locally or elsewhere. The eight survivors were examined by me on May 29, 1893, nearly four years after inoculation. In six of them there was no thickening or any indication of the site of inoculation, and no tubercles had developed anywhere. In the two remaining patients there was, in one a thick crop of tubercles, and in the other a diffuse infiltration of the skin, with tubercular masses on the face and ears.

In these two cases an eruption of tubercles occurred some time after the injection in anæsthetic lepers of products derived from the attempted culture of leprosy bacilli. Whether these eruptions were *propter hoc* as well as *post hoc*, is a difficult question. There are two possible fallacies:

1. The anæsthetic lepers might have developed tubercles independently of any injection. I have never seen a pure anæsthetic leper develop tubercles, but Leloir [1] quotes three cases, so we must admit the possibility.

2. The injection of micrococci or other irritant products of attempted cultivation may, through the febrile disturbance thus set up, have liberated bacilli already present in the peripheral nerves, and these, by their entry into the lymphatics of the skin and subcutaneous tissues, may have brought about tuberculation.

It is evident that experiments made on subjects already leprous can only have a partial value, but in view of the extremely rare occurrence of tuberculation in pure anæsthetic lepers, the trial seemed worth making and recording.

2. *Inoculation of Leprous Nodule or other Leprous Material.*—The classical example of inoculation of a healthy man with leprous nodule, is the inoculation of the Hawaiian convict Keann by Dr. Arning,[2] in the Oahu jail on September 30, 1884. The case is so well known that I need only refer to it very briefly here. A small piece of leprous nodule was introduced beneath the skin of the left forearm, and a month later the patient suffered from pain in the left shoulder, elbow, and wrist, accompanied by painful swelling of the ulnar and median nerves. There was no fever and only very slight constitutional disturbance. During the next six months the neuritis

[1] Op. cit., p. 209.

[2] Archiv fur Dermat. und Syph., January, 1891.

gradually decreased, and a small leprous nodule formed at the seat of inoculation. Leprosy bacilli could be detected here sixteen months afterward. In September, 1887, distinct symptoms of leprosy developed, and in another year the disease was fully established. Though at the time Dr. Arning made the experiment he was assured by Keann himself, and by those who knew him, that his family was free from leprosy, it afterward came out that his son, nephew, and maternal first-cousin were lepers either before or after the date of the inoculation. It would thus appear that in addition to the strong racial predisposition to leprosy which exists in Hawaiians, there was in Keann's family a peculiar aptitude for taking the disease. It is therefore quite possible that he may have had latent leprosy when he was inoculated. Moreover, as Arning points out, we have at present no criterion of the living leprosy bacillus, so that the bacilli in the inoculated nodule may have been dead at the time of the experiment. From whatever point we look at it, we can by no means regard the inoculation as conclusive, and Arning himself freely admits that it is not a crucial test.

Nearly forty years ago a Norwegian physician [1] inoculated himself and twenty healthy individuals with blood and fragments of cutaneous tubercle, or with blood or pus from such tubercles. All those who were inoculated were watched for many years, but they remained absolutely healthy.

Profeta [2] inoculated himself and nine other people. The observations extended over sixteen years, and were negative. The materials used were pus from leprous ulcers, and blood from tubercles and from anæsthetic patches. These were rubbed into the scarified skin or into raw surfaces produced by blisters, or injected beneath the skin by means of a Pravaz syringe. Similar experiments have been made by Danielssen, Holst, and Jitsch,[3] all with negative result. Hansen [4] inoculated anæsthetic lepers with material obtained from tuberculated lepers, but no development of tubercles took place.

In the Trinidad Leper Asylum I inoculated thirty anæsthetic lepers in December, 1887, and January, 1888, with fragments of cutaneous leprous tubercle. In 1889 three more anæsthetic lepers were inoculated with pieces of tubercle taken during acute leprosis, *i.e.*, fever accompanied by an outbreak of tubercles. I thought that possibly during these acute attacks the cutaneous nodules might contain living bacilli, and thus their inoculation might be followed by a development of the disease.

Since the inoculations were performed, nine of the patients have died and one has left the asylum. In none of them was any development of tubercles noted. The remaining twenty-three were examined on May 29, 1893. Twenty-two of them were absolutely free from tubercles, though in one of them, three months after inoculation, there was a subcutaneous nodule to the outer side of the cicatrix, about the size of a No. 6 shot. This, however, had disappeared in another month.

The twenty-third patient showed infiltration of the skin of the trunk, upper extremities, and face, with large masses of tubercle on the face and ears. This patient has already been referred to as having been also injected with culture products. It is therefore evident that we cannot say whether he became tuberculated as a result of the leprous nodule inoculation, of the culture injection of both of these, or independently of them.

Putting all the inoculations together we find that out of a total of forty anæsthetic lepers inoculated with either tubercles or cultures or both, two developed tubercles afterward, but it is impossible to say if this was the result of the inoculation.

Thus the evidence hitherto obtained from experiments performed on man may be regarded as almost entirely negative, no case being beyond the possibility of doubt.

4. **Vaccination.**—Of late years the antivaccination party, after exhausting every other argument against vaccination, has endeavored to show that leprosy is often spread in this way.

Probably the case which is most often quoted is that published by Gairdner [1] in 1887. A doctor in a tropical island vaccinated his own child from a native child who afterward became leprous. Another white child was vaccinated from the doctor's child, and both these children also developed leprosy.

Though Professor Gairdner carefully avoided expressing any opinion, and merely gave a statement of such facts as were known to him, the case was at once seized by those anxious to prove the communicability of leprosy by vaccination. A perusal of the case, however, shows that the details are very few, and insufficient to establish any conclusion. Moreover, leprosy was endemic in the island, so that the possibility of deriving it from outside sources was always present.

Daubler,[2] two years later, published an account of two women on Robben Island, Cape of Good Hope, both of whom, he believed, contracted leprosy through vaccination. They were vaccinated with lymph obtained from a patient who afterward died of tuberculated leprosy. In the first patient the site of inoculation swelled a few days after the puncture and became brown in color, but no true vaccine vesicle formed. After the swelling had subsided fever and rigors occurred, and by the eighteenth week there was a discolored tumefaction of the right frontal eminence. The second patient, two months after the vaccination, showed the typical leonine aspect of a tuberculated leper. These cases are frequently quoted, but clinical experience does not warrant the belief that such an essentially chronic disease as leprosy is produced so soon after inoculation.

More recently a long series of cases by Dr. Roger Chew, of Calcutta, has been published. A similar attempt has been made to show that leprosy was communicated by vaccination from diseased to healthy persons. The data, however, are very scanty, and the cases are open to the objection which obtains in those already quoted. In Bengal there are districts where the percentage of lepers is as high as, or higher, than in any other part of India, though, as will readily be seen by a reference to the annual reports on sanitary measures in India, Bengal is by no means the most vaccinated province.

The proposition may be stated as follows: If vaccine lymph be taken from a child in a locality where leprosy is endemic, and if such lymph be sent to a country free from leprosy, and a healthy child in such country, and who had never quitted the country, be vaccinated with such lymph, and if this child, after vaccination and without leaving the country, develop leprosy, then it may be taken as proved that leprosy is communicable by vaccination.

An experiment somewhat approaching the hypothetical one just described, has been performed in India. Surgeon-Major Pringle [3] was sanitary commissioner in the Northwest Provinces for twenty years, from 1864 to 1884. During this period he was in the habit of bringing down vaccine lymph at the end of each hot season from British Garhwal, a markedly leprous district, and using it for vaccinating in the plains between the rivers Ganges and Jumna, where the proportion of lepers was far smaller.

The census returns for the districts in question are as follows:

	British Garhwal.	District between Ganges and Jumna.
1867–72	20 to 30 per 10,000	1 to 5 per 10,000
1881	10 to 20 per 10,000	1 to 5 per 10,000

Thus not only has leprosy fallen in British Garhwal, but in the districts vaccinated with lymph therefrom the proportion of lepers has remained stationary.

As the number of individuals vaccinated with the

[3] Paper at British Medical Association, Bournemouth, 1891.

lymph under consideration was gradually accumulating for twenty years, making due allowance for removal by death and other counteracting influences, such as the diminution of leprosy in British Garhwal, we should expect that by 1881 the figures would show some evidence of the increase of leprosy which is alleged to follow the use of lymph collected in leprous districts. This increase, however, does not appear in the census returns, and we may fairly discredit its existence.

Various direct experiments have been made bearing on the subject of vaccination and leprosy.

Arning [1] in Hawaii vaccinated three lepers and examined the lymph. He found bacilli in the lymph and crusts in a case of extensive tuberculated leprosy in which the skin contained bacilli. In two cases of pure anæsthetic leprosy he found no bacilli.

In the Trinidad Leper Asylum [2] I made twenty-seven examinations of pure and impure lymph from vesicles raised in tuberculated, anæsthetic, and mixed lepers. Ehrlich's method of staining failed to show leprosy bacilli in any of the specimens, and animals vaccinated with lymph from lepers did not develop leprosy. I also vaccinated an anæsthetic leper with lymph from a mixed leper. Typical vesicles rose and ran the ordinary course, but there has been no development of tubercles. This experiment was done seven years ago.

Dr. Simpson vaccinated some lepers in Calcutta and described bacilli in the vaccine lymph.

At the Almora Leper Asylum [3] unusual facilities were offered, through the kindness of the authorities, for making an exhaustive study of vaccine lymph from lepers. Accordingly Dr. Buckmaster, Surgeon-Major Thomson and I had all the available lepers vaccinated. Eighty-seven were so treated, and of these forty, twenty-one males and nineteen females developed vesicles which were examined. Ninety-three cover glasses were prepared, and in no case were leprosy bacilli undoubtedly found. Suspicious-looking rods taking fuchsin were seen in one case in vesicles raised over tuberculated ears, and in another case in vesicles over anæsthetic patches.

But even if we regard these cases as positive and give them their utmost value, they have little or no bearing on the question at issue, for no vaccinator would be likely to vaccinate a leper over a tubercle or anæsthetic patch, and use the lymph obtained from such vesicles for vaccinating healthy individuals.

We may conclude therefore that the weight of evidence given in this section goes to show, 1, that the alleged cases of transmission of leprosy by vaccination are open to serious doubt, and 2, that, assuming the presence of bacilli to be necessary to produce leprosy, no danger need be apprehended from the vaccine lymph of even an actual leper, provided he is vaccinated on apparently normal skin. *A fortiori* therefore there is no danger of transmitting leprosy by using as a vaccinifer a child born of a family in which leprosy exists.

5. Practical Experience.—Almost all the alleged instances of communication of leprosy from one person to another have occurred in countries where the disease is endemic, and are therefore open to the fallacy of concomitant variations referred to in other sections.

The following case, which came under my notice during 1892, is a typical example of the histories so often quoted, but it has the additional merit that to a great extent I was able independently to verify the dates.

A man consulted me for a perforating ulcer of the foot. I discovered also anæsthesia of the upper extremities and decided that he was a leper. He then told me that five years ago he lived for six months with a notoriously bad woman who had been discharged from the Leper Asylum for misconduct. At that time he said he was healthy. About two years after he left the woman, ulcers formed on his feet and he lost sensation in his hands.

Some months after seeing the man I accidentally came upon his name in the register of out patients for 1890. He was entered at that time as a doubtful case of leprosy. Thus an unexpected corroboration was afforded of the patient's statements as to dates, for, from what he told me, he must then have had initial symptoms for about six months. From the entry in the register it is clear that these symptoms were not sufficiently pronounced to justify more than a doubtful diagnosis.

Cases like the above are met with from time to time, but it is seldom that the dates given can be confirmed. Indeed they often break down on cross-examination.

Very important negative evidence exists in Trinidad. For twenty-five years the lepers in the asylum have been nursed by Dominican Sisters. During this time these nuns have been in the closest contact with the lepers, washing and dressing ulcers and gangrenous extremities so that their hands have been constantly soaked with leprous discharges. No sister at the Trinidad Asylum has ever developed the disease.

It is true that Father Damien died of leprosy at Molokai, but when we remember how rapidly leprosy has increased in the Sandwich Islands in spite of segregation, we must admit that he may have derived the disease from an outside source.

During our investigations in India we were brought in contact with many cases of supposed contagion of leprosy. As will be seen on reference to the Report of the Leprosy Commission,[1] all these cases broke down on examination with the exception of that of a sweeper at the Calicut Leper Asylum, who had been employed in dressing the ulcers of the inmates for twenty-three years. Two years before our visit he had developed leprosy. Even in this case there was a discrepancy as to dates, an old inmate of the asylum asserting that the sweeper had suffered from leprosy for at least six years, but that he was apparently healthy twenty years ago.

The extreme difficulty of getting any coherent statement as to dates from an oriental is, however, so well known, that we must take the case for what it is worth. The dates given by the two men are fairly approximate.

But the only case which is free from the fallacy of concomitant variations already mentioned is that reported by Dr. Hawkley Benson,[2] of Dublin. A man after twenty-two years' service in India returned to Ireland with fully developed leprosy and was shown by Dr. Benson at a meeting of the Dublin Medical Society in 1872. He died a year and a half later. During this last period of his life his brother slept in the same bed with him and wore his clothes. This brother, who had never been out of the United Kingdom, developed leprosy about three years after the death of the first patient, and was shown by Dr. Benson at a meeting of the Dublin Medical Society, in 1877. It is much to be regretted that photographs of the two brothers were not taken, but I am informed on good authority that there were present at the meetings of the society, doctors who had seen leprosy abroad and who were therefore capable of confirming the diagnosis.

Cases of leprosy in persons living in a leprosy free country and who had never quitted it are also reported by Dr. Edmund Atkinson [3] in Maryland and by Dr. Rees [4] in Stepney. In neither of these cases, however, was actual contact with a leper proved, though there was a strong suspicion of it in Dr. Atkinson's case.

In discussing any case recorded in a country free from endemic leprosy, it must also be borne in mind that the diagnosis between leprosy and syphilis, especially in their early stages, is often extremely difficult.

Assuming the diagnosis to be correct, Dr. Benson's case remains as the only one in which all other possible sources of origin were excluded and in which practical experience pointed to a communication of the disease from one person to another.

6. The Alleged Increase of Leprosy.—Closely connected with the question of communicability of leprosy is that of the increase of the disease. If leprosy is communicable in any high degree we should expect a rapid increase all over the world, for segregation is not absolute anywhere.

In Hawaii[1] the official returns show 274 lepers in 1868; in 1888 there were 749 lepers segregated at Molokai and about six hundred at large; at the end of 1890 there were 1,213 lepers in the custody of the Board of Health, the highest number ever reached; and on March 31, 1892, there were 1,115—a decrease of 98 during the period. At the latter date it was stated that only 17 lepers and 60 suspects were known to be at large.

The above figures show that up to 1888 there was a very rapid increase of leprosy in spite of segregation, but that in the last five years there has probably been a slight decrease. In estimating the value of these figures it must however be remembered that great vigilance on the part of the authorities evokes greater efforts on the part of the leper population to avoid detection and segregation. It is therefore quite possible that in 1892 more than seventeen lepers were hiding in the mountains and remote country districts. More time must elapse before the value of segregation in these islands can be accurately gauged.

In Memel[2] Dr. Rosenthal reports a slight increase of leprosy. No case seems to have been known there before 1882. In that year the first case occurred, and seven more cases were noted up to 1889. No communication could be traced with Russia, where the disease is known to be endemic.

Turning now to countries where for many years little or no trouble has been taken to insure absolute segregation, the published figures show a very different result.

1. Trinidad.—Only three official enumerations of lepers have been made in Trinidad since the island was ceded to the English.

In 1813 Sir Ralph Woodford, wishing to establish a leper asylum, caused an official inquiry to be made as to the number of lepers in the island. Seventy-three were then found.

In 1815 the question of the founding of this asylum came before the Legislative Council, and the same Governor ordered another inquiry. This time the result was seventy-seven lepers. The population of the island was then given as 32,000.

The next inquiry was ordered by Sir William Robinson, and was completed in 1890. Every effort was made to obtain full returns, the chief sources of information being the district medical officers and wardens. The result showed a total of 414 lepers, of whom 210 were inmates of the Leper Asylum. The census next year showed the population of Trinidad to be 200,028.

Calculated from the above figures we find that the percentage of lepers in 1815 was .242, while that in 1891 was .206. It must in fairness be stated that the latter figures are not quite accurate, for the leper enumeration was completed in 1890, while the general census was taken the next year. The figures, however, are sufficiently approximate.

The question may be stated in another way: If there were 77 lepers in a population of 32,000 in 1815, how many ought there to be in 1891, with a population of 200,028? The answer, when worked out, is 481.

Allowing, therefore, a liberal margin of possibly undetected cases over and above the 414 recorded in 1890, we may fairly conclude that in Trinidad leprosy has not increased relatively to the population, but, if anything has slightly decreased.

2. India.—The recently published report of the Census Commissioner, Mr. J. A. Baines, shows an absolute decrease of leprosy in India since the last census. The lepers enumerated were:

In 1881	131,660
In 1891	127,056

There is thus an absolute decrease of 4,604. Mistakes and omissions have no doubt been made by the native enumerators, but these obtain in both censuses, though the probability is that diagnosis has been more exact in the last enumeration.

An important point, however, is that in the 1881 census, no lepers were returned from Upper Burma, Rajputana, Travancore, and the Central Province States, whereas the 1891 census shows 2,960, 1,708, 968, and 1,259 respectively for these districts, or a total of 6,895. It is extremely unlikely, to say the least, that in 1881 there were no lepers in the above-mentioned areas, and it is therefore highly probable that the actual total decrease is very much greater than that shown by the figures.

3. Norway.—The figures for Norway are often quoted. I have not yet been able to get any returns later than 1885. In 1856 there were 2,900 lepers. In 1885 there were 1,195 lepers. During this period of thirty years there was a steady fall, with the exception of a slight rise in 1859. Until 1885 there was no compulsory isolation of lepers. In that year a law was passed authorizing the detention in asylums of those who would not or could not sufficiently segregate themselves in their own homes.

Dr. Kaurin,[3] writing this year says that in the eight years which have elapsed since restraint became legal 99 lepers have been admitted to the Reknaes Asylum, of whom only 14 came in by reason of the new law. It is therefore evident that in Molde at least, legislation has so far had little to do with the admission of lepers to the asylum. The figures and dates already given are sufficient to show that the decrease of leprosy in Norway has been almost, if not entirely, independent of compulsory segregation.

4. Iceland.—Mr. Jeaffreson,[4] who visited Iceland in 1892, states, on the authority of Dr. Schierbeck, that there were 148 lepers in Iceland in 1800, and about 35 in 1892. He also states that the deaths from leprosy in 1768 were 73 per 1,000, while in 1868 they were 15.7 per 1,000. It would appear that leprosy is fast becoming extinct in Iceland, in spite of the entire absence of segregation.

5. Finland.—Dr. Fagerlund[5] reports that at the present time there are 51 lepers in Finland, of whom 32 are males and 19 females. The disease is disappearing from many parts of the country. In Töfsala and Gustaf, where leprosy was formerly almost endemic, there is now not a single case. In Aland, where there was at one time a hospital devoted to lepers, there is now only one person with the disease. Most of the cases are of considerable standing; only a few are in the early stages. Isolation is not compulsory in Finland.

6. North America.—During the last fifty years very many Norwegians have immigrated into the Northwestern States of North America (Wisconsin, Iowa, and Minnesota). With them a good many lepers have come over from Norway. These have been registered and kept under observation by the State Board of Health. No further isolation than the use of their own beds and utensils is required, and this, as a rule, is readily carried out by the patients or their friends.

Dr. Hansen[6] visited America in 1888 to study leprosy in the immigrated Norwegians and their descendants. He found that out of about 160 lepers who had immigrated into the three States named only about 16 remained. Of these he saw 13. All the others were dead. Of all the descendants of the lepers, including the great-grandchildren of some of them, not a single one had developed leprosy. No case of leprosy had developed in any one born in the state, whether of Norwegian or other parents.

From the evidence brought forward in this section it appears that in Hawaii there was a rapid increase of leprosy until a few years ago, and that the present number of lepers at large is doubtful; that in Memel there

[4] Virchow's Archiv, Band cxiv., 1888.

has been a small development of leprosy in the last decade; that in Trinidad there has probably been, if anything, a slight decrease in the proportion of lepers to the general population; that in India there has been a marked absolute decrease; that in Norway there was a steady decrease long before compulsory segregation was thought of; that in Iceland and Finland the disease has become almost extinct without the help of isolation; and that in the Northwest States of North America, where leprosy was not endemic, the immigration of Norwegian lepers has not been attended with any prejudicial result to the rest of the community, nearly all the imported cases having died, and no new cases having occurred.

The limits of this paper are already reached, but did time and space permit, it could be shown that in most of the countries in which leprosy is endemic, the alleged recent increase of the disease either has not occurred or is far less than is commonly supposed.

The conclusions arrived at in the foregoing sections may be finally summed up as follows:

1. Leprosy is probably due to a bacillus, and theoretically we must admit the possibility of its inoculation.

2. The experimental inoculation of leprosy in man or animals has never succeeded beyond the possibility of doubt.

3. It has not been proved that vaccination has conveyed leprosy.

4. While practical experience points to a possible communication of the disease from one person to another, the weight of evidence shows that this must be extremely rare, and under very exceptional conditions.

5. Leprosy has steadily decreased in many countries without any attempt at compulsory segregation, while in other places it has increased in spite of isolation of lepers.

6. The immigration of lepers into leprosy-free countries has not in recent times been followed by any appreciable spread of the disease.

7. For practical purposes leprosy may be regarded as less dangerous to the community than tuberculosis, and as requiring no greater precautions than those taken against the spread of that disease.

THE USE OF STRYCHNINE AND PARALDEHYD IN ALCOHOLISM.[1]

By GILBERT VAN VRANKEN, A.B., M.D.,

SAN DIEGO, CAL.

THAT the two great needs of patients suffering from alcoholism are sleep and food, and that of these two sleep is needed the more is, I think, generally conceded. Then the treatment must naturally have these ends in view. And although chloral hydrate, opium, bromides, veratrum viride, ammonia, alcohol, and quite a number of other drugs have been used and are still recommended in the treatment of alcoholism, from some observation and reading and a limited experience we think in strychnine and paraldehyd we have something not only quick to act and safe, but far more satisfactory in many ways than the older drugs. During a service as interne of an Eastern hospital we had charge of an alcoholic ward for six months. Here, with the approval of the visiting staff, we treated about fifty cases with these two drugs. Thirty of the fifty were very shaky, had exaggerated reflexes, and could eat or sleep very little if at all; thirteen more were delirious, and the remainder of a milder type. There were but two deaths—one, a woman, was in a state of coma when admitted and died two hours after admission; the other, a young man, seemed in no way affected by the treatment and died on the third day after entering the hospital. It was found necessary to strap down but three or four of the whole number, though several were kept in closed rooms and watched day and night.

Chloral hydrate, though used by some, has been found very unsatisfactory in the practice of many physicians, both because it is dangerous to the average alcoholic subject and because it often does not quiet the patient. We could name one hospital where, some years ago, there were two deaths but a few hours apart, due to the effects of this drug given for delirium tremens. Such instances, we think, are not very rare.

Professor William H. Thomson, of the University of the City of New York, recommends veratrum viride when the pulse is full and bounding, and so in danger of delirium or convulsions. He begins with a five-minim dose and repeats with a one-minim dose every hour until there is vomiting, or the pulse comes down. This we have seen used with good results in two cases, and have given it in two other cases where result was nil. We took the drug from the same bottle that had been used for the other two cases, so our failure could not have been due to the preparation. The cases, however, were not typical.

At the Bellevue Hospital Insane Pavilion, Dr. Fisher gives, in cases of acute mania, hyoscyamine, gr. $\frac{1}{60}$ hypodermically every four or six hours, until the patient is quiet. Here the results are certainly excellent, and we should think this drug might be very useful in delirium tremens, but have never seen it used. Being very expensive it would certainly have one recommendation, in common with the "gold cure," for alcoholism.

Several English authorities recommend ammonia in the treatment of alcoholism, showing how it takes the place of the alcohol and so keeps up the strength, etc. Nearly all physicians use bromide. Some to avoid the irritation of the bromide of potassium or ammonium give bromide of sodium only; others prefer equal parts of bromide of sodium, potassium, and ammonium. Aside from the danger of large doses the disturbance to the stomach and the diarrhœa following the use of bromides make quite a serious objection, especially when there is cirrhosis, as so frequently there is.

The use of strychnine for alcoholism has been advised by Loomis, Strümpell, and several others, some even claiming it has a specific action. Dr. Loomis said last year, in the course of one of his lectures at the University, that he had employed it in several severe cases with excellent results. He gave it with the needle, if the stomach was in bad condition, in doses of a twenty-fifth of a grain every four hours, and kept this up for two or three days if necessary to get the patient steady.

Of paraldehyd, Bartholow, in the last edition of his "Materia Medica and Therapeutics," says, "It has many of the qualities of chloral but none of its dangers. It does not paralyze the heart, for if given in lethal doses respiration stops first. In its action, first the cells of the cerebrum are affected, and sopor is induced without a preceding stage of excitement. Next to the cerebral hemispheres the medulla and then the cord are affected. The effect of paraldehyd is not so persistent as that of chloral, but frequent administration of the one can safely compensate for the greater power of the other." Bartholow further quotes a number of French authorities and says this drug has been used successfully in treatment of delirium tremens, also in strychnine poisoning. This last point shows that, to some extent at least, one of these drugs counteracts the effect of the other; an argument for the safety of giving both at the same time. Their use, we think, furnishes the argument for their efficiency.

Fresh air, sunshine, and cheerful surroundings without personal restraint are as wholesome to alcoholic patients as to any other, and perhaps more necessary than to some patients. The diet of these fifty cases was generally some preparation of milk at first, and this was given whenever the patient called for drink, and in such quantities as he would take. Other food was provided as soon as it could be digested. The bowels were moved daily, and the urine drawn or stupes applied if necessary. This often was necessary, for many of these patients could boast of several attacks of gonorrhœa and consequently strictures were the fashion. The following thirty cases are selected because they were of the more severe kind, and were under observation longer than the others. Twenty-four of these are nearly the same in many points, and so are tabulated:

[1] Read before the San Diego County Medical Society, October 6, 1893.

	Case.	Symptoms.	Other diseases coexisting.	Treatment.	Time.	Result.
I.	Brady	Trembling, exaggerated reflexes, and general irritability.	Mitral regurgitation	Strychnine sulphate, gr. $^1/_{25}$, every 4 hours (hypodermically).	3 days	Improved, and discharged by his request.
				Tinct. ferri chlor., ♏ x., every 4 hours.		
II.	McElvain	Trembling, exaggerated reflexes, and general irritability.	Subacute rheumatism	Strychnine, gr. $^1/_{25}$ (hypodermically)	1 day	Improved greatly.
				Sod. salicyl., gr. xxv., t. i. d.	16 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	15 days.	
III.	Webber	Trembling, exaggerated reflexes, and general irritability "thinks he sees them."		Strychnine, gr. $^1/_{24}$, every 4 hours (hypodermically), if awake	2 days.	
				Paraldehyd, ʒ j., every 3 hours till asleep	2 days.	Improved greatly.
				Bromid. and nux. vom. mist., ʒ ss., every 4 hours.[1]	10 days.	
IV.	Layland	Trembling, exaggerated reflexes, and general irritability: can neither eat nor sleep.		Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically) if awake.	3 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	1 day.	
				Paraldehyd, ʒ j., every 2 hours till asleep	3 days.	Improved greatly.
V.	O'Neil	Very nervous and could not sleep.		Paraldehyd, ʒ j., every 3 hours till asleep.		
				Strychnine, gr. $^1/_{32}$, every 4 hours	5 days.	Improved greatly.
VI.	Young	Nervous: cannot eat nor sleep		Paraldehyd, ʒ j., every 2 hours.		
				Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	4 days.	Improved greatly.
VII.	Crogan	Nervous: cannot eat nor sleep	Mitral regurgitation and aortic stenosis.	Paraldehyd, ʒ j., every 4 hours	5 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	11 days	Improved greatly.
VIII.	Devine	Nervous: cannot eat nor sleep	Cerebral congestion	Mist. bromid., grs. xx., every 4 hours, er got, ice, etc.[2]	3 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	9 days	Improved greatly.
				Tinct. cinch. co., ʒ ss., t. i. d.	9 days	
IX.	Cullen	Nervous; cannot eat nor sleep	Acute bronchitis: subacute gastritis.	Ammon. chlor. mist., bismuth and pepsin.		
				Strychnine, gr. $^1/_{32}$, every 4 hours.		
				Paraldehyd, ʒ j., every 2 hours	1 day.	
				Sulfonal, grs. xxx., daily	3 days	Improved greatly.
X.	Bridge	Nervous: cannot eat nor sleep	Opium poisoning (acute)	Stomach-pump, caffeine, etc.		
				Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	5 days.	
				Strychnine, gr. $^1/_{25}$, every 4 hours	5 days.	
				Paraldehyd, ʒ j., every 2 hours	5 doses.	Improved greatly.
				Tinct. cinch. co., ʒ ss., t. i. d.	5 days.	
XI.	McGovern	Nervous: cannot eat nor sleep	Bronchitis	Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).		
				Paraldehyd, ʒ j., every 4 hours	2 days	Improved greatly.
XII.	Barker	Nervous: cannot eat nor sleep	Bronchitis (?)	Paraldehyd, ʒ j., every 2 hours.		
				Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	2 days	Improved greatly.
XIII.	Evans	Nervous: cannot eat nor sleep	Otitis media	Inflation, borac. acid, etc.		
				Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	2 days.	
				Strychnine, gr. $^1/_{30}$, every 4 hours	18 days	Improved greatly.
XIV.	Turner	Nervous: cannot eat nor sleep		Strychnine, gr. $^1/_{60}$, every 4 hours (hypodermically).	2 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	7 days.	
				Paraldehyd, ʒ j., every 2 hours	2 days.	
				Bromid. mist., grs. xxx., every 2 hours	2 days	Improved greatly.
XV.	Decker	Nervous: cannot eat nor sleep	Chronic interstitial nephritis, gastritis, rheumatism, etc.	Sod. salicyl., ammon. iod., etc.		
				Strychnine, gr. $^1/_{32}$, every 4 hours (hypodermically).	4 days.	
				Paraldehyd, ʒ j., every 2 hours, etc	4 days	Improved greatly.
XVI.	Murray	Nervous: cannot eat nor sleep		Paraldehyd, ʒ j., every 2 hours	2 days.	
				Strychnine, gr. $^1/_{24}$, every 4 hours (hypodermically).	2 days	Improved greatly.
				Strychnine, gr. $^1/_{32}$, every 4 hours	3 days.	
XVII.	O'Neil[3]	Nervous, etc., as the others		Bromid. and nux. vom. mist. (see Note 1	10 days	Improved greatly.
				ʒ ss., t. i. d.		
XVIII.	McEwen[3]	Nervous, etc., as the others		Bromid. and nux. vom. mist., every 4 hours alternating with mist. bromid. (see Note 2), grs. xxx., every 8 hours.	9 days	Improved greatly.
XIX.	Kehoe	Delirious		Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	2 days.	
				Paraldehyd, ʒ j., every 4 hours	2 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	2 days	Improved greatly.
XX.	Vorhagen	Delirious; became rational; stopped strychnine and delirium returned.		Paraldehyd, ʒ j., every 4 hours	2 days.	
				Strychnine, gr. $^1/_{24}$, every 4 hours (hypodermically).	2 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	1 day.	
				Sod. bromid., grs. xxx., every 2 hours	4 days	Improved greatly.
XXI.	Kennedy	Delirium, etc		Paraldehyd, ʒ j., every 2 hours	4 days.	
				Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	4 days.	
				Spr. frumenti, ʒ ss., every 2 hours	3 days.	
				Mist. bromid., grs. xxx., every 2 hours	3 days.	
				Sod. bromid., grs. xxx.	4 days	Improved greatly.
				Strychnine, gr. $^1/_{32}$, every 4 hours	4 days.	
XXII.	McGuire	Delirium, etc	Lobular pneumonia, etc	Tinct. aconite, ♏ j., every hour till pulse came down; later, digitalis, ammon. chlor., etc.		
				Paraldehyd, ʒ j., every 3 hours	1 day.	
				Strychnine, gr. $^1/_{60}$, every 4 hours (hypodermically).	3 days.	
				Sod. bromid. grs. xxx., every 2 hours	2 days	Improved greatly.
XXIII.	Stagg	Delirium, etc	Acute bronchitis	Paraldehyd, ʒ j., every 2 hours.		
				Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	2 days.	
				Strychnine, gr. $^1/_{32}$, every 4 hours	8 days	Improved greatly.
XXIV.	Bowman	Vertigo; delirious, etc.[4]		Bromid. mist., gr. xxx., every 2 hours	1 day	Grew worse.
				Applied straps.		
				Paraldehyd, ʒ j., every 2 hours	1 day	Improved greatly.
				Strychnine, gr. $^1/_{24}$, every 4 hours (hypodermically)	1 day.	
XXV.	Mrs. Judd	Delirium, etc		Strychnine, gr. $^1/_{25}$, every 4 hours (hypodermically).	2 days.	
				Paraldehyd, ʒ j., every 2 hours	2 days	Improved greatly.
XXVI.	Burns	Delirium, etc		Strychnine gr. $^1/_{32}$, every 4 hours.		
				Mist. bromid., gr. xxx., every 4 hours	6 days	Improved greatly.

[1] R. Potass. bromid., gr. xv.; Tinct. nux. vom., ♏ x.; Sps. ammon. aromat., ʒ j.; Tinct. capsici, ♏ xv.; Tinct. cinch. co., q. s. ad. ʒ ss.

[2] R. Kal. bromid., natrii bromid., amm. bromid., āā; in aquam.

[3] These two cases had no strychnine or paraldehyd.

[4] Under treatment slept 1 day and 2 nights.

Some Exceptional Cases.—CASE XXV.—A. W——, aged twenty-five, had been drinking heavily for some time; fell in street, and when brought in had two or three slight cuts and abrasions about face, one being across the nose. Had mitral regurgitation and hypertrophy of left ventricle. Had vertigo and saw double, and floating bodies; a general tremor, rigors, and vomited a greenish fluid. Stopped vomiting by wine of ipecac., ♏ j., every hour. Was now delirious. Gave strychnine, gr. $^1/_{24}$, every four hours (hypodermically), and paraldehyd, ʒ j., every four hours. Later gave mist. bromid., gr. xxx., every four hours. Pulse became weaker, and

gave aromatic spirits of ammonia and brandy. None of the medicines produced any effect, and on the third day temperature[1] went up to 106.2° F. and he died. It was thought at the time that there was no cerebral injury, but as there was no autopsy this is somewhat doubtful. The heart lesion may have played an important part in this case, but the history pointed strongly to alcoholism as the most important factor. He did not sleep at all, but the delirium was not of the violent sort.

Case XXVI.—M. L——, had had convulsions and pulse was now 105, full and hard. Gave veratrum viride, ♏v., one dose, and ♏j. every hour during night, with no result except he had no convulsion. He was quite delirious, but not violent. Temperature, 100.3° F.; respiration, 29. Gave paraldehyd, ʒ ij., every three hours, and strychnine, gr. $\frac{1}{30}$, every four hours (hypodermically); no result. Then for a few days gave chloral hydrate, grs. x., mist. bromid., grs. xxx., every four hours; no result. Now gave morphine sulph., gr. $\frac{1}{4}$, every three hours, and applied strait-jacket, but there was no improvement. Dull pain in hands and arms. Finally, under Dover's powder and bromides, sleep was secured, but when awake the delirium returned. Now gave potass. iodid., grs. x., gradually increased to grs. l., every four hours, and cod-liver oil, t.i.d. After thirty days he became rational and remained so. This was thought to be a sort of pachymeningitis, due to alcoholism.

Following is a case of exceptional, though accidental, treatment:

Case XXVII.—A. K——, had been out of the hospital on leave for the day and returned intoxicated. He had taken now by mistake a mixture containing tincture of aconite, ʒ ij.; tincture of belladonna, ♏xv.; tincture of cimifuga, ♏xv., and wine of colchicum, ♏xlv. About one hour later this was discovered. He was in good condition, except, of course, intoxicated; pulse was full, rapid, and rather incompressible. A part of the stomach contents was now removed by the pump, but it was impossible to wash out the stomach properly, and tartar emetic, grs. ij., was given. This did not operate for about two hours, but the pulse continued rapid and strong, and patient was very violent. Later whiskey and digitalis were given, p.r.n. The patient went out next day in good condition, and was not seen for some weeks, when he returned intoxicated.

Case XXVIII.—M——, came in with severe hemorrhages from the stomach. Treated with ice, opium, etc., and fed by rectum. After two days he suddenly developed delirium, and jumped from the window to ground, a distance of about twenty feet. He received no injury of any account. Was kept in bed with some little difficulty and given hypodermics of strychnine, gr. $\frac{1}{30}$, every four hours, and paraldehyd, ʒ j., or sodium bromide, grs. xv., every two hours, when awake, for four days. Now gave the strychnine, gr. $\frac{1}{32}$, by stomach for six days. Discharged in good condition.

Case XXIX.—H——, while delirious had wandered from home and laid out all night. Right hand was frozen. He was unconscious. Temperature, 91° F. (per rectum); respiration, 15. Was put in warm bath and regained consciousness. Two hours later temperature the same. Six hours later, 97.2° F., and ten hours later 100.3° F. It soon became normal and remained so. Treatment: External heat, aromatic spirits of ammonia, tincture of capsicum and whiskey, also injections of strychnine, gr. $\frac{1}{15}$, every four hours for two days. He developed bronchitis, but was taken home on second or third day in good condition.

Case XXX.—S——; very nervous; had been exposed to cold, and temperature was 94° F., per rectum. Applied heat and gave aromatic spirits of ammonia and tincture of capsicum. Ten hours later temperature was 100.4° F. Gave the bromide and nux vomica mixture, and he became delirious. Now gave paraldehyd, ʒ j., alternating with bromides, ʒ j. Also tincture of ferri chlor., ♏xv., t.i.d. Discharged in good condition after seventeen days.

In all of the foregoing cases the alcoholic element is believed to have been the predominating one. In some of them co-existing diseases are mentioned because they called for treatment or modified the symptoms of the alcoholism. Many had chronic nephritis or cirrhosis of the liver, or some valvular lesion of the heart, for nearly all these people had been hard drinkers for years.

In several cases not reported here strychnine and paraldehyd were given as a part of the general treatment for alcoholic patients suffering from phthisis or pneumonia, and the result was beneficial.

We were usually cautious about giving these drugs when there was advanced disease of the heart. But in other cases the paraldehyd was given generally every two hours till the patient was asleep. This means that about two or three drachms were given a day, though sometimes five or six were necessary, and in one or two cases it was given in two-drachm doses repeated every three hours till three or four doses had been given. The strychnine was given hypodermically generally and in doses of a fiftieth to a twenty-fourth of a grain while the patient was awake, and for three or four days. Then the strychnine was given by the stomach and the paraldehyd at night only. Patients were allowed to sleep from twenty-four to thirty-six hours, being aroused only for nourishment, etc. After four days the paraldehyd was often replaced by bromides or sulfonal, grs. xxx.

It will be observed that in two or three of these cases strychnine and paraldehyd were not given, but the nux vomica and bromide mixture (note 1, page 712). This was often given after three or four days and when the symptoms were not so severe.

Cod liver oil, iron, pepsin, etc., were often used, for most of these patients had not been as much used to food as they had been to cold and wet weather, and consequently were quite anæmic, had gastritis, rheumatism, and many other complaints.

Opium, it will be seen, was given but once when there seemed to be some pachymeningitis, and here, strange to say, it appeared to be of some use. Alcohol was used but two or three times, *i.e.*, when the heart was very weak.

Most of these patients on entering the hospital were tormented by the thirst for alcohol, but many on leaving said they had no desire for it, and we know did not go back to their old habits at once. A few of those that could be followed we know abstained for some months, but at this date it is impossible to say if any experienced what is called "a cure."

A Dramatic Suicide.—For novelties in the line of self-destruction France has long enjoyed an unchallenged reputation. The latest reported suicide of this character took place a few weeks ago, during the visit of the Russian naval officers to Paris. While the train conveying the foreign guests to Versailles was crossing the Seine a young woman stood on a parallel bridge waving French and Russian flags, and shouting, "I see and I die. Long live Russia!" she jumped into the river and was drowned. When her body was recovered it was found that she was clothed only in garments made out of French and Russian flags.

[1] In most of the tabulated cases there was little rise in temperature, and this is, I think, the rule where there are no complications and where there is not a fatal issue. In the following case the rise of temperature was probably due to septicæmia.

A. G——, had been suffering from delirium tremens two or three days when he shot himself in left chest. (This case was not in my service and I do not know the treatment.) The delirium became more violent; on third day temperature was 105° F., and it continued to rise, till the fourth day it reached 112° F. and death resulted.

Autopsy, twenty-four hours after death. There was no rigor mortis. Great discoloration. No noticeable change about the wound. Decomposition had set in. Blood, black and thin; heart, empty; lungs, congested and pleura thickened about wound; kidneys, possibly fatty; brain, partly decomposed. Bullet had passed through seventh rib, the pleura, diaphragm, and partly through the muscular coat of the stomach, where it was found.

GASTROSTOMY IN STRICTURE OF THE OESOPHAGUS.[1]

By H. D. NILES, M.D.,

SALT LAKE CITY, UTAH.

On account of the comparative rarity of the operation, and from the fact that the more recent modifications in the views of leading surgeons regarding it, are not yet incorporated in the text-books of surgery in common use, it is hoped that the account of the following cases, coupled with a brief review of the past and present state of the operation and the conditions which give rise to it, may not prove uninteresting. If the interchange of ideas which the introduction of this subject may elicit shall result in any or all of us being better prepared to meet these grave emergencies when they arise in our practice, the object of this paper will have been attained.

Mrs. B——, sent in from a neighboring city, aged sixty-nine, for the past year had been distressed with symptoms which she and her friends attributed to some form of "dyspepsia." She suffered but little localized pain, but swallowing was accomplished with some difficulty, followed by distress along the whole length of the gullet and later by rejection of a whole or part of what she had eaten. She said that many times the food seemed to lodge at a point just back of the lower part of the thyroid gland. During the thirty days preceding her coming to this city her local symptoms and consequent loss of strength became alarming. She was able to take only liquid food, and it is probable that only a small proportion of this reached the stomach. I first examined her February 21st. She was confined to her bed, very much emaciated and apparently receiving no nourishment by the mouth. Pulse 80, regular and weak; heart normal; temperature, 98° F.; urine normal except a specific gravity of 1032. She was suffering no acute pain, but was very weak and physically and mentally depressed from lack of nourishment. She said that she was hungry all of the time. A medium-sized œsophageal bougie passed easily to eleven inches from the incisors, but the smallest instrument could not be coaxed further; and apparently at that time absolutely no fluid penetrated beyond the stricture. The occlusion seemed complete. Could obtain no history, family or personal, favoring the probability of the obstruction being due to malignant or specific disease. Trauma could be excluded. Physical examination failed to reveal the presence of a tumor or aneurism that might press upon the œsophagus. Her age of course pointed strongly to malignancy, but there had never been a trace of blood from the parts, no localized pain, and no pus could be noticed on the bougies after their withdrawal.

The history of the case given somewhat in detail is not different from that which many or all of you have studied in your own practice. A patient dying a horrible death from slow starvation probably due to an epithelioma which had not yet commenced to ulcerate, or possibly to fibrous thickening of the walls of the œsophagus. What treatment can we recommend in such cases? If the occlusion was not complete, the introduction of food into the stomach through a catheter, or dilatation of the stricture with sounds, or by some of the newer ingenious methods, or linear electrolysis, or œsophagotomy might be considered. But in a case like the foregoing, one must decide upon one of three courses:

1. We may relinquish the case as entirely beyond our skill to mitigate the sufferings or effect a cure. To deprive any sane patient under any circumstances of every vestige of hope is certainly the last course to be adopted.

2. We may confine ourselves to a strictly palliative treatment, keeping the patient's strength up as long as possible by rectal enemas, and quieting her sufferings with sedatives while we and she wait for death.

3. The establishment of a gastric fistula through which nourishment can be introduced, and the patient sustained while complete rest of the parts might stay the progress of the disease and even permit sufficient dilatation by retrograde catheterization to allow food to be taken in time by natural channels.

[1] Read before the Salt Lake City Medical Society.

Against the latter course was, first, the high mortality which the statistics show attend these operations; second, at best it was likely to prove only palliative. In favor of it was first the doubtful possibility of the stricture proving to be benign; even if malignant life might be prolonged some months; and lastly, should the operation prove a failure in both of these respects, she would at least escape the horrors of a death by starvation.

I concluded not to urge or even advise the operation; but after a full explanation to the patient and her friends to leave the decision entirely to them. In accordance with their desire the operation was performed with the assistance of Doctors Maclean, Root, and Witcher, on February 21st. Chloroform was the anæsthetic selected, and the usual antiseptic precautions were observed.

Fenger's incision was made and the stomach secured after some difficulty, for it was collapsed and lying at least five inches from the wound. It was held by two tenaculi while fine silk sutures were used to stitch it to the edge of the abdominal wound, the peritoneal surfaces being carefully apposed.

Notwithstanding the patient's age, weakened condition, and the length of time she was under the anæsthetic, she rallied well and quickly, and for the succeeding five days the temperature did not reach 100°, or the pulse get above 90; nor were there any indications of peritonitis. On the morning of the 24th (seventy-two hours after the operation) the stomach being completely and pretty firmly adherent to the abdominal wound, an incision was made of sufficient size to admit a small rubber tube, and the transfixing needles were removed.

About three ounces of hot peptonized milk was introduced by means of a funnel attached to the tube. From this time until the 27th, small quantities of peptonized milk and beef tea was given through the tube. The stomach would only tolerate a certain amount, when nausea supervened. In the meantime this nourishment was supplemented by nutritious enemas. On the morning of the 27th she showed signs of sinking, and died of exhaustion that night. An autopsy could not be obtained.

Fifty six years ago, Egebert, a Norwegian surgeon, recommended this operation for stricture of the œsophagus, but to Sedillot is due the credit of having first performed it on a human being. This operation was done in 1849, upon a man dying of cancerous stricture, with a fatal result in twenty-four hours. In 1853 both Sedillot and Fenger operated, with fatal results. In 1858 and 1859 Cooper Forster, and in 1866 Bryant and Curling, each operated; all of these gastrostomies were unsuccessful. In spite of these failures, the operation found a few good men who believed it to be a proper procedure in appropriate cases, and had the courage to undertake it. But it was not until 1874 that a single success was achieved, when Sidney Jones, of St. Thomas's Hospital, performed his third operation.

This most encouraging result, occurring as it did almost coincident with the introduction of antiseptics into surgery, gave new hope, and while gastrostomy has not kept pace with other abdominal operations in their success and rapid advancement in professional favor, it nevertheless, at the present time has an assured position among legitimate measures of surgical relief.

J. Greig Smith, in his new, admirable work on "Abdominal Surgery," says: "The actual conditions for which the operation may be performed, are the following:

"1, Cancerous stricture of the œsophagus; 2, cicatricial contraction of the œsophagus; 3, obstruction, by pressure, of growths outside the œsophagus; 4, malignant disease of the pharynx or the mouth; 5, ulcerative, chemical or traumatic destruction of the walls of the œsophagus; 6, congenital closure of the œsophagus."

He further states: "In a cancerous case I am of the opinion that considerable weight ought to be given to

the desire of the patient after an honest, impartial statement of the possible and probable results have been put before him."

Bryant writes in 1885: "That though in the fifty or sixty cases in which gastrostomy has been undertaken for cancer, life has never been prolonged for more than six months, the relief it has afforded to those who have been subjected to it is sufficient to prove that it is based upon a sound principle and a humane practice; the operation having been undertaken more with a view of mitigating the horrors of a death from hunger and thirst, and of prolonging what remained of life, than from any curative object. I am free to acknowledge that the advantages given by the operation are worth the risk."

Eichorst and Dujardin both speak in favor of the operation in malignant disease of the gullet. Gerster records six cases, one of which lived thirty-two days. We would infer that he would employ it as a *dernier ressort*. Moulin would only resort to gastrostomy in a few exceptional cases. He favors Symond's method of permanent tubage. Of course this could only be applicable to permeable strictures. Erichsen and the late Dr. Hayes Agnew never modified their earlier conservative opinions of the value of gastrostomy in malignant stricture. Wyeth says: "When the occlusion is so complete that the œsophagotome cannot be employed, or if from any reason this method of procedure is contraindicated, and inanition is threatened, the operation of gastrostomy is imperative."

In the new American Text-book of Surgery is found; "A resort to this operation is indicated in cases of malignant or cicatricial stenosis of the œsophagus or cardiac orifice of the stomach advanced to such an extent that the introduction of food *per viam naturalem*, or by the use of tubes, is no longer possible." "The results of this operation in malignant disease have thus far not proved very satisfactory, as it has seldom been performed before the patient had reached an extreme degree of marasmus, which in itself proved the greatest source of danger." (Why wait, then, until tubage is no longer possible, and the patient so much reduced?)

Jacobson writes: "I have performed gastrostomy seven times, in each case for cancer of the œsophagus; in three patients the operation was asked for too late; in one, my seventh case, the patient died from an accident for which I am responsible; the other three recovered well. One, a young married woman, had had symptoms six months; she was in the fourth month of pregnancy when operated on; she lived in comfort for six months and died, a month after giving birth to a child at the full time, of extension to the lung. Another patient lived between three and four months, and would have survived longer if it had not been for his carelessness as to exposure. A third was alive and progressing satisfactorily when last heard of four or five months after the operation."

Such in brief has been the history of gastrostomy and the views regarding it of a few of our leading surgeons. All admit its frequent utility in non-malignant stricture, and a very small minority only are willing to relinquish the hope that it may prove useful as a means of mitigating the sufferings and prolonging the life of one dying of starvation from cancerous stricture of the œsophagus. Still it must be admitted that it is rarely undertaken except as a *dernier ressort*. Abdominal section for the removal of an ovarian cyst, or a gangrenous vermiform appendix or for intestinal obstruction or in cholecystotomy was a few years since reserved until every other means had failed and the patient's strength was exhausted. A high mortality followed and these operations were condemned by the laity and some of our ablest surgeons as being but little better than murder. To-day it is known that the danger incident to opening the abdominal cavity under proper antiseptic precautions is comparatively slight and thousands of lives have been saved by these operations that under the old "wait and hope" system of treatment would have been sacrificed.

This has largely been brought about by early diagnosis and prompt operative interference when needful. While it cannot be claimed that gastrostomy, especially when performed for malignant stricture, is ever likely to have as wide a field of usefulness as any of the operations referred to, the exercise of the same precision in diagnosis and promptness in operating that lowered the mortality and brought these operations into such repute, would unquestionably exert a somewhat similar influence on gastrostomy.

An inquiry into the causes of death in quite a large number of cases of gastrostomy leads me to believe that not less than seventy-five per cent. are due either to shock or to a peritonitis lighted up by the escape of the contents of the stomach into the peritoneal cavity. If this be true an operation before the patient's health is greatly impaired would immeasurably lessen the first danger, and by giving a longer time to assure ourselves of the completeness and firmness of the union between the stomach and the walls of the abdomen, prevent the latter. With these two dangers eliminated should not gastrostomy be the first choice instead of the last in the treatment of some of the conditions producing œsophageal stricture?

For example: as soon as we are positive that we have to deal with cancerous disease or ulcerative destruction of the œsophagus, would it not be in accordance with the laws of good surgery to relieve the parts of the irritation produced by swallowing and the presence of food, and to forego the use of sounds, bougies, and tubes and by gastrostomy afford that complete rest to the parts that we would insist upon were the disease located elsewhere? and should other operative measures or local medication be decided upon, would they not be more effectual if the patient's general health was well sustained by nourishment through the gastric fistula and the local disease kept free from all sources of irritation?

These questions I beg to submit for your consideration and discussion this evening. For myself I have no hesitation in expressing my convictions that while the framing of fixed rules for our guidance must wait upon that perfection in our diagnostic methods that shall enable us to recognize early and predict with certainty the progress, suffering, and termination of the disease without operative interference, that that day is already here in some cases and not very distant in others, and with it the time when gastrostomy should sometimes be the first choice of treatment instead of the "*dernier ressort*" that it now is.

A Wonderful Discovery by a Berlin Dermatologist.—Dr. Lassar, who may be remembered as the secretary of the International Medical Congress in 1890, proclaims that he has discovered a cure for malignant neoplasms of the skin. His remedy is arsenic, which he would appear to think has never been used before. Commenting upon this brilliant discovery, the *Medical Press* says: "It is surprising that one holding a position like Lassar should be so seemingly ignorant of the use of arsenic. He first shows a few cases to the Berlin Medical Society as interesting, which, through courtesy to his former position, are admitted without criticism. In the *Wochenschrift*, a few days later, appears a lengthy account of three cases magically cured of cutaneous cancer by the use of arsenic. The paper tacitly assumes these to be the first of their kind where healing has been accomplished, except in the case of Fehleisen, who inoculated the neoplasm with erysipelatous virus, but excited the suspicion that the curative agent was more fatally active than the original growth. Histories and photographs are given of this latest arsenic success in the *Wochenschrift;* abstracts are taken promptly by the German Medical Puffing Agency and pressed upon the notice of the many guileless editors, who, anxious to be first with things apparently novel and startling, are betrayed into hurrying before their readers some elementary antiquity more ridiculous than could be imagined to emanate from the mind of the late secretary of an International Congress."

CEREBRAL HEMORRHAGE ASSOCIATED WITH NARROWING OF AORTA.

By CHARLES E. NAMMACK, M.D.,

VISITING PHYSICIAN GOUVERNEUR HOSPITAL; ATTENDING PHYSICIAN NEW YORK HOSPITAL, OUT-PATIENT DEPARTMENT.

The ambulance was summoned from Gouverneur Hospital to a lodging-house on September 20, 1893, and the surgeon found there a young man of whose previous history nothing could be learned, except that he had fallen to the floor, unconscious, ten minutes before. He was brought to the hospital, and, on admission, found to be in complete apoplectic coma, with the following symptoms: Face, pale; skin, cold and clammy; pulse, strong, regular, and rapid; stertor, absent; vomiting, absent; pupils, dilated equally, and immobile; convulsions, absent; hemiplegia, present on left side. The heart-apex beat was outside the nipple line; cardiac impulse, strong; endocardial murmurs heard at both mitral and aortic orifices. The apparent age of patient was twenty-two.

The case was thought to be a beautiful illustration of cerebral embolism, and the attention of the house staff was called to the differential points in favor of this diagnosis and against cerebral hemorrhage. The patient died two hours after admission, and the autopsy proved the correctness of the late Dr. Austin Flint's statement[1] that the physician who ventures upon a positive diagnosis in apoplexy incurs a risk of being convicted of an error at the autopsy. An extensive pial hemorrhage was found. For further examination and study the brain, heart, aorta, kidneys, and spleen were taken to the pathological laboratory of the New York Hospital. The pathologists, Drs. Frank Ferguson and George P. Biggs, very kindly examined the specimens for me, and Dr. Ferguson furnishes the following report: Brain: The convolutions are flattened. There is a hemorrhage in the meshes of pia, generally distributed over the base, but especially abundant over the pons and along the course of the right middle cerebral artery and its branches. There is a hemorrhage in the interior, size of a pullet's egg, situated external to the right corpus striatum and continuous with the hemorrhage in the meshes of the pia in right Sylvian fissure. The hemorrhage in the interior of the brain is peculiar in that the clot is oval and its exterior smooth. The brain tissue limiting the clot is also smooth and does not present the ragged-edged appearance of an ordinary apoplexy. The vessels leading to the clot were carefully examined, but no gross lesion was detected. The heart is normal in size. The left ventricle is dilated and the endocardium thickened. There are low vegetations on the auricular surface of the mitral valve, but the capacity of the valve is normal, and it appears competent. The cusps of the aortic valve are thickened, and one of them is notably retracted. The aorta is small, measuring, when laid open, 5¼ ctm. above the aortic cusps; the thoracic aorta measures 4 ctm., the abdominal aorta, above the superior mesenteric, 3½, and just above the iliac bifurcation, 2½ ctm. Its wall appears normal. The kidneys, to the unaided eye, appear normal. The spleen shows great hypertrophy of the Malpighian bodies.

Microscopically, the brain is found to be the seat of very numerous minute hemorrhages, many of which follow the course of the vessels. The perivascular spaces are very generally filled with blood. The vessels of the pia and the branches which pass down into the cortex contain large numbers of small round cells; their walls are the seat of vast numbers of these cells, and in one of the branches of the middle cerebral artery there is a thrombus which appears to be extensively composed of these small round cells. The pia is everywhere infiltrated with them. There are numerous small hemorrhages in the pia at distant points from the large hemorrhage at the base already described. The kidneys show numerous areas of small round cells and some of the tufts are solid globes of fibrous tissue. The spleen shows simple hypertrophy of the Malpighian tufts and intense hyperæmia.

[1] Flint's Practice, 6th edition, p. 656.

It will be seen from Dr. Ferguson's report that the pathological condition was that of arteritis syphilitica, and that this condition, rather than the narrowing of the aorta, was the efficient cause of the hemorrhage.

Aside from the fallacy of the bedside diagnosis the case is of considerable interest on account of the small aorta. Dr. Ferguson presented a similar case at the meeting of the New York Pathological Society, May 14, 1884,[1] in which cerebral hemorrhage, independent of disease of the vessels, existed. He informs me that he has seen other cases, and that Virchow's museum, in Berlin, contains a collection of seventeen specimens. Dr. H. N. Heinemann has also put on record a case[2] presented at the Pathological Society's meeting of September 22, 1886, and in the discussion a case of Dr. George L. Peabody's is mentioned. This last case is published in the "Transactions of the Association of American Physicians," 1891, p. 169. Leyden[3] records a case in which autopsy showed hypertrophy and dilatation of the heart, stenosis of aorta, and embolism of the artery of the fissure of Sylvius. Fraentzel[4] publishes one case, thirty-four years of age, death from cyanosis and dyspnœa, no mention of cerebral hemorrhage. Also a case, twenty eight years of age, death from pulmonary tuberculosis, no cerebral hemorrhage recorded. Kuessler[5] has two cases in young adults, in each of which the aorta would only admit the little finger, but the condition of the brain is not recorded in either. Loriga[6] presents two cases of narrow aorta. Autopsy in one showed cause of death to be croupous pneumonia. Eppinger[7] brings forward a case of cerebral hemorrhage in a young man, associated with narrow aorta, and tabulates forty-two cases of stenosed aorta, in which cerebral hemorrhage appears only once as the cause of death. A later writer, Kriegk,[8] gives marasmus as the cause of death in this same case. The patient was a male, aged ninety-two. Kriegk reports three cases of his own, in one of which, a boy, aged eleven, autopsy showed cerebral hemorrhage. He also tabulates the cases to date, fifty-six in number, and gives cerebral hemorrhage as the cause of death in but three, viz., his own, Eppinger's, and Ermann's. The case of Ermann[9] showed embolism of the right internal carotid and cerebral softening. In a second case of Kriegk's,[10] occurring in a woman, aged twenty eight, death resulted from apoplexy, and a softening was found in the left hemisphere with a fresh apoplectic focus in the right.

Although the number of cases of narrowing of the aorta is comparatively large, in but few has cerebral hemorrhage been associated, and it is difficult to draw conclusions as to the causative influence of one condition upon the other. Authors of text-books upon diseases of the nervous system, at least those with which the writer is familiar, do not mention anomalies of the aorta in the etiology of cerebral hemorrhage; with the exception of Dana[11] the general opinion seems to be that a diseased or weakened arterial wall is the essential local factor in producing cerebral hemorrhage.

For assistance in abstracting the foreign literature of the subject, the writer is indebted to Dr. Boleslaw Lapowski, of the New York Hospital staff.

29 EAST TWENTY-FOURTH STREET, November 1, 1893.

Pharyngitis sicca, atrophic nasal catarrh, anæmia accompanying tertiary syphilis, are sometimes greatly improved, indeed to a degree far greater than it has been in my hands possible with any other agent, by small doses of Fowler's solution.—ALLEN.

A SIMPLE METHOD OF CLOSING LARGE OPERATION WOUNDS BY SLIDING SKIN-FLAPS.

By GEORGE F. SHRADY, M.D.,

SURGEON TO ST. FRANCIS HOSPITAL, NEW YORK.

Having often experienced difficulty in closing the large gaps in those cases, more especially of cancer of the breast, in which extensive removal of integuments has been necessary, and having tried many methods, I merely wish to offer the following as giving me the greatest satisfaction.

It may be considered, to some extent, a modification of the sliding curved flap used in cheiloplasty. If we take an extreme case in which there is an elliptically shaped wound with edges otherwise impossible of approximation, we have a condition to which this method is well adapted. A straight incision is made at right angles to the short axis of the ellipse, and at a suitable distance is terminated by two sweeping, well rounded, curves which diverge in opposite directions. They then resemble in contour the outlines of the buttocks. The same flaps may be made, if necessary, in a reverse direction on the corresponding opposite side of the gap. When these flaps are loosened from their bases throughout their whole extent, their free edges easily slide toward each other along the lines of the curves and are brought together with sutures, thus closing the entire wound by converting the long axis of the ellipse into a straight line.

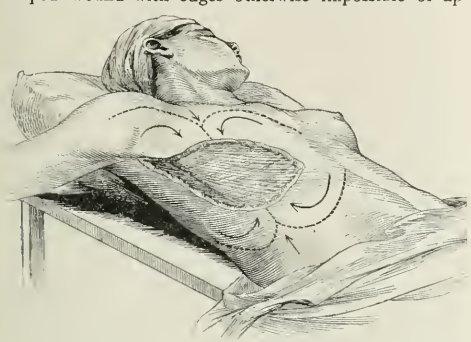

Fig. 1.

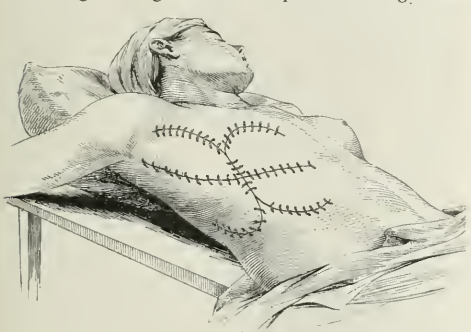

Fig. 2.

This can be made plainer by reference to the accompanying illustrations (Figs. 1 and 2). By this procedure, what might otherwise be a bare surface left for tedious granulation, is covered by healthy integument, the suture lines of which heal by first intention. Care must be taken in forming the flaps, that their tissues are of uniform thickness throughout, that the blood-supply at their bases is not jeopardized, and that all tension is avoided. Very frequently but one set of flaps will be required. The objection may be raised that an extensive dissection is oftentimes required to liberate the flaps, but this is overcome by the fact that in the end a complete natural skin-covering is obtained, and the excessive formation of cicatricial tissue is prevented.

The triangular-tongued flaps at the points of intersection of the curves may be more or less loosened to allow of better adaptation to the spreading curves of the main flaps as they are brought into position.

There is never danger of sloughing of any portions of the flaps when care is taken to avoid tension.

REGENERATION OF RADIUS AFTER ITS REMOVAL FOR OSTEOSARCOMA.[1]

By CARL BECK, M.D.,

SURGEON TO ST. MARK'S HOSPITAL AND TO THE GERMAN POLIKLINIK, NEW YORK.

Rosa M——, eighteen years of age, shows an excellent family record and never was sick until one year ago, when she first noticed a small lump on the upper third of her right radius. There was no history of a trauma or of an hereditary disease. As the tumor was painless, the therapy at first consisted in applying home made ointments only.

About nine months ago, when I first met her, she showed a healthy general appearance, had a good appetite and normal temperature and pulse. On the upper third of the radius, and coherent with it, was a hard, painless tumor of a regular oval shape, and of hen's egg size. The interosseous space was filled by the tumor.

My diagnosis was osteosarcoma, wherefore I advised immediate extirpation. This advice was not followed, however, as a colleague promised her to cure her by the use of iodide of potassium and of inunctions. (Undoubtedly syphilis was suspected.) But when, three months later, the growth, instead of decreasing had increased, she asked me herself for an extirpation. At this time, that is, six months ago, the tumor had reached the size of a man's fist, and occupied now a considerable portion of the ulna also. Besides, there was a good deal of pain complained of. She had lost considerable, felt weak, and her appetite was poor. The temperature was normal, but the pulse frequent. When I, by extirpating under Esmarch's constriction, had exposed the radius, I found that it, from its neck to about one half of an inch above its lower end, was taken up by the neoplasm. Softening of the bones was advanced so far that easily I, without using saw or chisel, could lift it up with the sharp spoon. Of the ulna, which three months ago could well be separated from the growth, about three inches had to be resected now. Although the periosteum could only partially be saved, the enormous cavity, which was packed with iodoform gauze (a few stitches had diminished its size somewhat), closed after two months. At the same time the whole bone was entirely regenerated. The function, six months after the operation, is perfectly normal. The neoplasm was examined by the pathologist of St. Mark's Hospital, who pronounced it to be an osteosarcoma containing spindle and giant cells. The patient enjoys excellent health and shows no abnormities whatever. Bearing in mind the extremely bad prognosis of this kind of malignant tumors it is evident that an operation should take place as early as possible; wherefore it is to be deeply regretted, if antisurgical colleagues are extending their specific experiments over too long a period.

It is perfectly proper to try to form an opinion "ex juvantibus et nocentibus," but if after, say three weeks, elapse under the administration of mixed treatment a tumor increases instead of decreasing, the medical treatment should not be carried on any further. If clinical examination should leave any doubt, it would be safer to make a microscopical examination of a piece, obtained either by excision or harpooning.

[1] Case presented to the surgical section of the Academy of Medicine, November 13, 1893.

Progress of Medical Science.

Supraclavicular Inspiratory Depression in Early Phthisis.—Dr. Revillet once more draws attention to the above phenomenon. Practitioners know how difficult the diagnosis of early phthisis may be and how important it is to have this point clearly settled. The search for bacilli in any sputa that may be expectorated is in suspected cases helpful. But one may have to wait a long time before any micro-organisms can be detected. In like manner dulness on percussion and crepitation may be absent, and we have to rely on the presence of such delicate signs as rough, feeble, and wavy breath-sounds in solving the problem. In weak girls the detection of feeble and staccato respiration at the apex may mean nothing; but, according to Dr. Revillet, if to such ambiguous signs is added unilateral inspiratory depression of the supraclavicular fossa the presence of tuberculous pleurisy of the apex may be unhesitatingly affirmed, this sign being pathognomonic of the lesion. It may be absent, however, in cases of apical pleurisy where adhesions coexist consecutive to diaphragmatic or parietal pleurisy, for in such instances the play of the apex of the lung is interfered with. In five post-mortem examinations of patients in whom during life this supraclavicular inspiratory depression had been noted, thick and tough adhesions of the corresponding apices were observed. In two instances atrophy of the platysma myoides and of other muscles of that region was observed. If, in such a case, traction is made on the lung from below the phenomena may be easily reproduced. It must not be forgotten that evident signs of early phthisis may be masked by the râles of bronchitis, and here, again, Dr. Revillet's sign may prove to be of use. When the tuberculous process is more advanced both apices become attacked and the sign loses its significance; but in this case, again, the greater amplitude of the depression at one apex enables the medical attendant to say that that apex was the first attacked. In a period of four years Dr. Revillet has proved in the post-mortem room that these apical adhesions may disappear; and, in fact, this observer tells us that, as the tuberculous deposit may be limited to the pleura, and as, moreover, these adhesions may be absorbed, a comparatively favorable prognosis may be made in these cases. Of twenty-six cases kept under observation during four years only one terminated fatally, the rest remaining *in statu quo* or becoming only very slowly worse.—*La Semaine Médicale.*

Successful Operation upon a Splenic Abscess in a Child.—Dr. Sendler has reported the case of a girl, four years of age, of good family history, and previously never ill, who, without known cause, began to fail in health (*Medical News*). The child was languid, without appetite, vomited occasionally, and from time to time suffered with diarrhœa. A fall down steep stairs was immediately followed by pain in the left hypochondrium and repeated vomiting. The pain became progressively more severe and a swelling formed in this region. At the same time the general condition suffered correspondingly. It could not be learned whether or not there had been fever, but there was no knowledge of chills. The skin covering the swelling was smooth and unchanged in color. The mass was immobile and yielded deep fluctuation. There was no evidence of involvement of lungs, pleura, or heart. It was recognized that an abscess existed, but its origin was not clear, although implication of the spleen received consideration. At all events, operation was believed to be indicated, and was accordingly undertaken. A free incision was made below and parallel with the left costal arch, revealing an abscess-cavity, with thickened walls adherent to the abdominal parietes, and containing inspissated pus of cheesy consistence. The abscess was about as large as a small hen's egg and occupied the body of the spleen. After the sac was evacuated a rubber drainage-tube was introduced into the cavity, the overlying tissues were sutured, and an antiseptic dressing was placed over all. Recovery ensued without complication. The etiology of the abscess could not be determined, although it is believed that it existed at the time of the fall, which resulted in its rupture, with the formation of inflammatory adhesions.

Ureteritis Membranacea.—Dr. Jaksch has reported the case of a woman, forty-five years old, who seven years previously suffered from pain in the back and right loin. Soon afterward there appeared pain in the left loin, sometimes attended with vomiting. Two years later a small calculus was passed, with severe colic, referred to the left kidney. Some relief followed this, but attacks of colic, vomiting, muddy urine, and painful micturition occurred at intervals, accompanied occasionally by rigors and fever. The urine was neutral in reaction, contained some albumin, and also some unbranched, translucent, ribbon-like structures about four inches long, arranged spirally. These bodies varied a little in breadth and resembled the similar appearances encountered in the sputum and fæces. This resemblance was still closer in that they consisted of mucin and fibrin. Microscopically, they were like Curschmann's spirals, but without the central thread. On the surface could be seen flattened epithelial cells, singly and in groups, such as are found in the bladder and ureter, amorphous masses, and crystals of calcium sulphate. Throughout the sediment were scattered amorphous masses composed of calcium carbonate, fine crystals of triple phosphate, well-formed crystals of calcium sulphate, and epithelial cells from the ureter and bladder. Neither cells from the renal tubes nor colorless corpuscles could be found. After rest in bed the pain in the loin disappeared, and the condition of the urine changed in a few days, the spiral formations ceasing to appear, and the crystalline forms becoming fewer in number. Sulphuric acid lemonade was administered, and the urine soon became acid, and in a few days the patient was dismissed, much improved.—*Medical News.*

Pental as an Anæsthetic.—Dr. P. F. Féodoroff has experimented with pental in general surgical anæsthesia. This substance does not become decomposed either in light or air; its specific gravity is about that of ether, and, like this latter, it is very volatile. Care must be taken to keep this substance removed from the fire; it burns with a very bright flame, but it has no explosive properties. The vapor of pental does not irritate the mucous membrane. According to Féodoroff, the duration of pentalization is from one to two minutes, and, the condition of anæsthesia once induced, it may be prolonged from two to five minutes. In about fifty per cent. of the cases the radial pulse is not modified, but otherwise the pulsations become more frequent, and sometimes there is arythmia. It is principally during the first minute that disturbances of the circulation show themselves; it is, therefore, very necessary to be circumspect during the primary inhalations, and not to have recourse to the concentrated vapor of pental, except after the first minute, when the action of the heart will already be regularized. It is important to call attention to two peculiar effects of the drug: 1. Analgesia occurs while consciousness is still retained; the patient executes all the orders of the physician, feels the contact of the instrument, but does not feel pain. It would, however, be imprudent to operate before the complete loss of consciousness; the majority of accidents which have happened during the use of pental were due to reflexes occurring in subjects insufficiently anæsthetized. 2. From ten to fifteen minutes after a first administration of the drug it may again be used without its action being weakened; it would even appear that the subjects are still more susceptible to its effect. One must also be careful never to operate with a patient in a sitting posture, but always in the recumbent position, for fear of dangerous accidents. To resume: Pental is an excellent anæsthetic in operations of short duration.—*University Medical Journal.*

Clinical Department

A SIGNIFICANT SYMPTOM OF AORTIC ANEURISM.

By JAMES ROSS, M.D.,
SURGEON OF STEAMSHIP MACKEY-BENNETT.

In the MEDICAL RECORD of August 12th appears a paragraph referring to a significant symptom in aortic aneurism. Last year I had a case answering nearly precisely the paragraph alluded to, and thus my reason for writing this article. My patient was one of our engineers on board ship, an Englishman, in his forty-sixth year. He was a very robust man, a hearty eater, and rarely missed his bottle or two of beer daily. Though evidently in good health he had always been extremely nervous about himself, often consulting me on the slightest provocation. I, being a ship's doctor, probably induced him to seek advice oftener than if I were paid out of his pocket. In January, 1892, he developed a slight hacking cough, with scanty expectoration, occasionally tinged with a minute quantity of blood. About March 1st, he experienced a sharp pain situated between inferior angle of left scapula and vertebral column, at times shooting up to the left shoulder. Pain was only severe at night, apparently most acute while lying on his back. Though I had examined him several times I could not satisfy myself that his symptoms were due to an aneurism or other tumor. I restricted his diet slightly, stopped his beer, and gave him a saline aperient mixture; his condition then considerably improved. While in port I thought of calling a consultant, but as he seemed better and was able to perform his daily work constantly, I hesitated till hope had vanished. One night in August I was hastily summoned to see this man, and after getting on board found he had had an attack of hæmoptysis and was very weak from the loss of blood. That this unlooked-for attack was due to aneurism was plainly obvious, and the chain of symptoms mentioned a consequence of its presence. The following morning a consultant was sent for, and just before Dr. Chrisholm's arrival at 9 A.M., patient had another seizure of hemorrhage, but not so severe as the former one. About midnight of the same day, or about twenty-five hours after the first hemorrhage, another attack of hæmoptysis quickly ended his life. A hasty and incomplete autopsy was held and an aneurismal sac was discovered about the junction of the transverse and descending aorta. It was seen to press on one of the larger bronchi, through which a small aperture had been made from erosion of the sac. The aneurism was apparently entirely free of a fibrinous clot, and had undergone considerable atheromatous change.

REMOVAL OF IMPACTED URETHRAL CALCULUS.

By J. C. HILL, M.D.,
ROCKLAND, ME.

William M——, aged forty, sailmaker, came to me in April complaining of great difficulty and pain in urination. Stream was very small and its passage always accompanied by pain and tenesmus; at times it was impossible for him to urinate, the penis being turgid and inflamed. This condition had existed for twenty-one years; the data being fixed indelibly in his mind by being prostrated at that time by excruciating pains in the region of the bladder and by the passage of bloody urine; since which time this condition dated. He stated that he had suffered from a chronic urethral discharge during that period, and had been twice treated for specific urethritis, which he had reason to believe never had existed. He had a constant feeling of abdominal distention, with an ever-present desire to micturate and "a pain in the back which made his life miserable." Pulse was rapid and feeble; skin sallow and moist; eyes had lost their brilliancy; frontal headache was of almost daily occurrence, an anxious and careworn expression of countenance, and the general appearance emaciated.

I passed a small catheter with some difficulty, owing to what I supposed to be spasm of the urethra, and relieved the distended bladder of thirty-two ounces of thick, high-colored, offensive-smelling urine. This urine upon standing rapidly precipitated a large quantity of phosphates.

Chemical examination of the urine discovered the presence of albumin, two per cent., but under the microscope no casts could be found. Pus cells were abundant.

Upon withdrawing the catheter it came in contact with a hard substance about 2.5 ctm. from meatus, which upon further examination proved to be a calculus. This portion of the penis was cocainized by urethral and hypodermic injection of an eight per cent. solution, the urethra incised, and the stone removed. The calculus weighed 2.5 grammes, was 2½ ctm. in length and 2 ctm. in breadth, ovoid in shape, with an irregular surface.

The parts healed by first intention; all urethral discharge ceased; subsequent examinations of the urine showed no albumin. The patient from morose became cheerful. All of his previous ailments disappeared. He gained rapidly in weight, and recovered an excellent degree of health.

A CASE OF HÆMATOMA OF THE VULVA.

By PAUL SKIFF ROBINSON, M.D.,
STONY CREEK, CONN.

October 23d I was called to attend Mrs. F——, aged thirty-two, in labor with her fourth child. The head presented in the L. O. A. position; pains were strong, and though she had a slightly flattened pelvis, the surroundings, attitude of friends, and impossibility of obtaining intelligent assistance, made me decide against interference unless some imperative indication should arise.

The first stage lasted ten hours, it being necessary to rupture the membranes, and about a half-hour later I noticed a decided tumefaction of the left labium majorum. This steadily increased, despite the application of cold and judicious pressure, until at the end of the hour the lip had swollen to the size of the two closed fists, was very sensitive to the touch, and giving intense pain to the patient. Fearing rupture if labor were allowed to continue for a much longer period, I applied forceps to the head, which was just beginning to bulge the perineum, and by gentle traction brought the head to the vaginal orifice. Then removing the forceps and supporting the tumor with the entire left and palm of the right hand, with the fingers I directed the head to press as much as possible toward the right side of the vulva, and at the end of the second pain thereafter the head was born; then quickly extracting the body by a finger in the axilla, all danger of rupture and laceration was passed. The placenta was easily removed by Credé's method, and after being washed and cleansed, the mother rested quietly.

The child was born slightly asphyxiated, but respiration was easily established, and it did well.

After-treatment consisted of cleanliness and the application of cloths saturated with a hot three per cent. solution of carbolic acid to the vulva, and at the end of the third day no sign of the tumor could be detected, and there has been no trouble since.

The cause I believe to have been obstruction of the pelvic veins, particularly the vaginal plexus, by the child's head, but why in this case only the left lip was involved, puzzles me.

A peculiar element in the case was the presence of a relaxed condition of portions of the internal saphenous vein of each leg, which the patient's husband tells me have in all previous labors been greatly distended; but at this time there was no unusual fulness or appearance of obstruction.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, December 2, 1893.

CARBOLIC ACID IN FULL STRENGTH IN SURGERY.

DR. OSCAR H. ALLIS, of Philadelphia, in a recent paper before the Philadelphia Academy of Surgery, draws attention in a suggestive way to the use of pure carbolic acid in the after-treatment of surgical wounds. He was led to investigate the effects of the application by the successful experience of Dr. B. F. Gardner, of Bloomsburg.

Dr. Allis thus describes the method, which had its origin in an accident: "When Lister introduced his paste Dr. Gardner used it quite extensively. After an application to quite an extensive wound surface he was surprised to find it turn white, and that he had used pure carbolic acid. He therefore immediately washed the surface and dressed the wound, keeping it open until oozing had ceased. The case did so well that it inaugurated with him a line of treatment that he has extensively employed. As a typical application let me take an amputation of the female breast. After its removal and the ligation of the bleeding vessels carbolic-acid crystals, dissolved in sufficient water for solution, are applied with a sponge to all parts of the cut surface. Immediately upon the application of the acid the tissues turn white, which is a guarantee of its thorough action. The wound surface is then washed with water previously sterilized by boiling, and then approximated with provisions for drainage. This is especially necessary, as for twenty-four hours the oozing must find ready exit. During the first few days there is a slight local hyperæmia along the borders of approximation, but this declines without crisis."

It is claimed for carbolic acid applied in officinal strength, 1. That no systemic absorption attends its use, and hence no danger, no shock. 2. That it is a local anæsthetic. Hence there is not as much pain after the operation. 3. That it is in a measure a hæmostatic, acting especially upon the capillary vessels. Although the use of the acid as a direct application to wound surfaces, diseased membranes, and fungoid granulations is not new, we have presented to us some thoughts on its extended employment which may perhaps be profitably directed into practical channels. The good results of its employment in the open methods of treatment of hydrocele are suggestive and instructive in this instance. In intestinal surgery it also has its given range of application. Intra-abdominal stumps are often tipped with the pure acid with good results.

While it is not considered necessary in ordinary operative wounds, aseptically treated, it would seem to be proper in those cases in which thorough antisepsis is otherwise doubtful or impossible. Against the claim that it produces necrosis are cited numerous cases in which after the deeper tissues were whitened with the characteristic coagulation the wound was closed, healing by first intention. It may yet appear that pure carbolic acid has a rôle of its own in just those exceptional cases; at least it is deserving of a cautious trial in proper hands.

HOW TO OVERCOME MALARIAL INFLUENCES.

MALARIA, by its vexatious persistency, wide distribution, and crafty insidiousness, is much like original sin. Both are looked upon as the birthright of most of us, and in such a view are generally accepted with becoming resignation and apathetic complacency. While many with comfortable assurance lull themselves into security when away from swamps and at different altitudes, others claim that the poison is everywhere, even in the highest mountain-tops, and still others maintain that there is no immunity save in a purely sulphurous atmosphere in a famous inferno not adapted to living creatures. Its history belongs to that of the world, and its defiance has been chattered in the teeth of every generation from the time our first parents went abroad. So we shall probably have it with us always, and when there is anything new in its history, development, or prevention we are alert with attention and patient with facts. And even when the old story is told anew we listen with eagerness for something we may have missed before, in order that we may keep our consciences clear and our receptive faculties in proper trim.

Indulging in these general reflections we have brought to our notice an abstract in *The Lancet* of Professor Tommasi Crudeli's views on the preservation of human life in malarious districts. As the distinguished writer is an acknowledged authority and has had a large experience with the disease, we may at the start become discouraged to learn that as yet we have no precise knowledge of the real nature of the malarious poison or the means whereby it can be extirpated from the soil of an infected locality. He also tells us that the poison inheres in the soil; that it is under the influence of season, temperature, and rainfall; that it is excited to fresh activity by all measures involving the disturbance of earth long left quiescent; that its ravages have been much reduced by drainage, by the conversion of naked soil into meadow land, and by the erection of houses and laying down of pavements for streets.

He also points out that the traditional precautionary measures long adopted in malarious countries have had two ends in view, viz., to reduce as much as possible the quantity of the malaria ferment which enters into the system through the air breathed and to prevent a lengthened abode of the same in the system. The first point is sought to be achieved by avoiding agricultural operations during those hours at which the malarious influence is most potent—viz., about sunrise and sunset. Hence, according to the writer, is really explained the much-misunderstood dictum of the ancient Sybarites: "If you wish to live long and well, do not ever see the rising or the setting sun." Another point of the greatest importance is to avoid breathing the air in close contact with

the soil, as it can be shown that the malarious poison rises only a short distance in a vertical direction. Thus in the Pontine marshes, an intensely malarious region, platforms four or five metres high are erected, upon which the people sleep in the open air with comparative impunity. In Greece, the jungles of the East Indies, and Central and Southern America, similar devices have been adopted with beneficial results. Another mode of eluding the malaria-laden air in close contact with the ground is to construct the dwellings in such a way that when the door is shut the internal atmosphere is renewed only by the strata of the local atmosphere which are near the roofs of the houses. This is managed in some localities by so arranging that the only opening in the outer wall is the door, and all the windows open on an inner yard at a higher level than the ground floor of the house.

It is advisable also to keep the windows of the houses closed in the morning and during the early hours of the evening, especially if any excavations should be going on in the neighborhood. Care should be exercised regarding the effects of placing vases of flowers in occupied rooms. Either these should be entirely excluded from houses when malaria is rife, or the utmost vigilance should be taken to secure thorough ventilation.

Many of these observations are old, and some perhaps are new, at least to a few of our readers. We present them as they are given us, while we cling to our quinine closer than ever.

THE "CELEBRATED PHYSICIAN."

We should like to get hold of the gentleman who masquerades as "a celebrated physician" in the public prints. He is a person quoted by all, yet familiar to none. Sometimes he is "a celebrated English physician," and then he has something to say about diet and drink. He is the person who some years advises the public to take two ounces of alcohol daily, while in other and drier times he asserts that spirits are poisonous in even the slightest amount; he advises people to take hot milk and cold tea, to wash the ears with ice water as a preventive of colds, to sleep with the head toward the north—or south—to wear garters and liver-pads and belts. The "celebrated French physician," who is less heard of nowadays than formerly, is more frequently credited with a *bon-mot* or some marvellous surgical or psychological contribution to newspaper science. The "celebrated German physician" utters some last word about the nature of disease, or advises daily baths. We regret to say that "the celebrated American physician" has not yet a market value in newspaper syndicates. Individually there are a few who are esteemed, but the class as a whole has not reached that height of public fame and breadth of public recognition which gives journalistic value to the title of "a celebrated American physician." Consequently we do not yet find this learned class advising horseback exercise for malaria, hot water for constipation, milk and Vichy for rheumatism, fish diet for gravel, and similar valuable additions to the personal knowledge of the masses.

Lately "celebrated physicians" have been concerning themselves greatly about the ladies. We quote the following:

"A celebrated physician on being asked 'What is the exercise most conducive to physical beauty in women?' replied, very decidedly, 'walking.'

"Tennis he declared to be too violent, and too much of it is likely to lengthen the arms and make the height of the shoulders uneven.

"Cycling renders women awkward in their walk. They gradually come to move with a plunging kind of motion the reverse of graceful, and frequently cultivate weakness of back, which makes them hold themselves badly.

"Riding is one-sided, and women who have habitually ridden for years usually have one hip higher than the other.

"Croquet really does not give exercise, and after a survey of all the ways he knew in which women take physical exercise he considered none so conducive to health and beauty of form as walking."

To this we say, in the name of the Prophet—Fudge! The above anonymous celebrity utters an opinion which is dogmatic, destructive, and audacious. It is read and quoted over the country. Thousands of people perhaps believe it; mothers begin to worry, stop their daughters from their sports, and set them to the inane task of pure and objectless pedestrianism. And, after all, "the celebrated physician" may have been only the reporter on a daily paper, with a fad to propagate.

As a matter of fact, no expert in physical training, or physician of practical experience, would agree for a moment with the celebrated gentleman quoted above. They would say that the physical training of every girl is a problem by itself; that properly applied calisthenics, with baths, could do most for physical development, and that out-door exercise should include something calling for the development of the chest—a thing walking does not accomplish.

We call upon our readers and the general public to look out for the "Celebrated Physician" of the prints. He is a dangerous man; he is a shield for dogmatism and quackery; he should no longer be quoted.

THE FIRST DISCOVERER OF ANÆSTHESIA.

The history of the discovery of anæsthesia in this country is a tragic one. Of the three Northern physicians who claimed the chief merit, Jackson died insane, Wells committed suicide, and Morton died as the result of a painful accident. As to the respective claims of these gentlemen, the Record has in times past expressed its views and will open no fresh controversies. Southern physicians, however, have always asserted prior claims for Dr. C. W. Long, and lately Dr. Luther B. Grandy, of Atlanta, has brought forward fresh documentary evidence in favor of this gentleman.

The story as related by Dr. Grandy is somewhat as follows: Dr. C. W. Long graduated in medicine at the University of Pennsylvania, in 1839. After spending a year in New York he returned to his home in Jefferson, Ga., and began the practice of his profession there.

While in Philadelphia he learned something of the exhilarating effects of ether. When he got home he used to amuse some of the young men about town by getting them somewhat intoxicated with the fumes of the drug. We do not mean to infer that this was done to any great extent. Probably a few whiffs were administered only. He found, however, that in a few cases

persons who had hurt themselves while intoxicated with ether suffered no pain. This led him to think that ether might be used in surgical operations. The first operation under ether was performed on James M. Venable, March 30, 1842, when a small tumor was removed from the neck.

The documentary evidence is furnished from Dr. Long's ledger.

JAMES VENABLE.

1842.

January 28th.—Sulphuric ether.	$0 25
March 30th.—Ether and excising tumor	2 00
May 13th.—Sulphuric ether	0 25
June 6th.—Excising tumor	2 00

The details of that first operation under ether have been published by both Dr. Long and Dr. Sims. Concerning the subsequent operations not much need be said. On July 3, 1842, Dr. Long amputated the toe of a negro boy for disease. On September 9, 1843, he extirpated a tumor from the head of Mary Vincent, of Jackson, Ga. On January 8, 1845, he amputated two fingers of a negro boy. The certificates of two witnesses to this operation state that the first finger was removed under the anæsthetic, and that the boy experienced no pain; that the second was removed without ether, and was very painful.

No other operations were performed prior to October 16, 1846, when Morton administered his "letheon" at the Massachusetts General Hospital. Dr. Long was a general practitioner in a small town and had two opportunities to test his discovery in major operations. It seems probable that he did not produce profound narcosis, and he was not entirely sure that it was ether and not mesmerism or idiosyncrasy which caused the anæsthesia.

There is little doubt, judging from the facts furnished by Dr. Grandy, that Dr. Long first used ether for allaying pain in surgery. He did not have opportunity, however, to test it fully or to carry out full anæsthesia. Credit for this must be given to his Northern *confrères*. We are quite sure, however, that Dr. Long deserves the honor which the State of Georgia proposes, viz., that of placing his statue in the Capitol at Washington.

THE PUBLIC HEALTH BILL.

WE are gratified to learn that the Public Health Bill of the Academy of Medicine, which has been widely circulated through our columns and by the Committee which has it in charge, is received with universal favor. Upward of one hundred letters have been received by the Secretary of the Committee from all parts of the country, pledging individuals and societies to earnest work in behalf of the measure. In many cases physicians have gone directly to the Congressman of the District, or to the Senator from the State, and personally urged the bill upon his attention. In several instances members of Congress have deliberately examined the bill thus brought directly to their consideration, and have expressed their approval of it. This is a kind of work which will in due time yield abundant fruits. We wish more Congressmen could thus have been seen in the quiet of their homes, and pledged to give the bill their personal attention when it is introduced into either House. Failing in that it is important that every medical man who has a personal acquaintance with Congressmen, whether in the Senate or in the House, should place himself in communication with such member, furnish him with a copy of the bill, and urge him to consider it favorably. Medical societies should each appoint a special committee whose duty it should be to memorialize Congress, and during the session maintain a close correspondence with the Committee of the Academy in order that there may be harmony of action, especially when emergencies arise in the progress of the bill requiring a concentration of efforts.

We feel justified in saying, for the encouragement of those engaged in this most patriotic service, that indications of success are daily multiplying. The New York Chamber of Commerce has resolved to aid the Committee, and its example will bring the co operation of the Boards of Trade throughout the country. Life Insurance Societies have indicated a desire to add the weight of their influence. We have reason, also, to believe that this measure will prove acceptable to the Government. There is, therefore, every inducement for the Committee to urge forward its work, and for the medical profession of every State to co-operate on the lines above indicated. In answer to inquiries, and for the benefit of those who may wish to communicate with the individual members of the Executive Committee, which has the bill in charge, we give their names, viz.: Dr. T. Gaillard Thomas, Dr. E. G. Janeway, Dr. Richard H. Derby, Dr. Stephen Smith, Dr. J. H. Girdner. Information and copies of the bill may be obtained from Dr. J. H. Girdner, Secretary, No. 31 West Thirty-eighth Street, New York.

News of the Week.

Dr. Stuart Eldridge, of Yokohama, was tendered a reception in this city by Dr. Matthew D. Field, on Saturday evening, November 25th. A large number of medical friends were present, and the occasion was an enjoyable one to all.

Thanksgiving for the Doctors.—In the present healthful state of the community the doctors have reason to be thankful that they are not in any danger of being ruined by prosperity.

A Tribute to the Medical Profession of New York.—At the one hundred and twenty-fifth annual banquet of the Chamber of Commerce, of New York, President Charles S. Smith paid a just tribute to the doctors of the city. President Smith said: "The city of New York and the whole country are under obligations to this Chamber for their prompt action when, a year ago, this country was threatened by an invasion of cholera, and the character which this Chamber has established during the one hundred and twenty-five years of its existence for unselfish devotion to the public welfare enabled it to call upon the public for a subscription to meet a possible emergency, which was responded to in the amount of $195,000, all of which, with the exception of $20,000, was returned to the subscribers. It is also a pleasing duty to acknowledge in this connection the important aid that was rendered to the Chamber by the Advisory Committee of Physicians of the New York Academy of Medicine; and, gentlemen, it is not too much to say that there is no body of men in

the city of New York who give so freely and gratuitously of their time and services to the poor and suffering as do the medical men of New York. If, in the final analysis of human actions, character is the standard of success or failure, then the physicians of New York deserve to wear the laurel wreath."

The Late Dr. John C. Peters.—At the stated meeting of the New York Pathological Society, held on November 22d, the following resolutions on the death of Dr. John C. Peters were unanimously adopted:

Whereas, It becomes our painful duty to announce the death of Dr. John C. Peters, a founder of the New York Pathological Society, a former President, and for a long period an Editor of its Transactions, therefore be it

Resolved, That this Society desires to place on record its appreciation of his long and valuable services in the different offices in which he served during a period of nearly half a century of continuous membership.

Resolved, That from the first meeting of this Society until his last attendance he has been a tried and faithful servant of its best interests, an ardent promoter of its highest aims, and an active participator in all its progressive doings.

Resolved, That his untiring zeal in the performance of his multifarious duties, his constant courtesy in discussion, his painstaking accuracy of observation, and his ever available and profound knowledge were qualities which commanded the highest respect of his associates, and stimulated the emulation of all who shared the results of his unselfish labors.

Resolved, That the remembrance of his genial disposition, modest manner, energetic spirit, and scholarly attainments will ever serve as a cherished lesson from the well ordered life of a cultured gentleman, an honored citizen, and a model physician.

GEORGE F. SHRADY, M.D.,
JOHN H. HINTON, M.D.,
LEWIS A. SAYRE, M.D.,
Committee.

The Eleventh International Medical Congress, which was to have met at Rome on September 24th, but was postponed on account of the cholera epidemic then prevailing in Italy, will be held from March 29 to April 5, 1894.

One Cigar too Many.—The late Sir Andrew Clark was so ardent in his crusade against overeating and overdrinking, and so firm in his belief that in a large majority of cases diet would do far more than drugs, that he was a little too much inclined to take it for granted that his patients were self-indulgent to the ruin of their health. Among the many anecdotes to which his views gave rise the following is one of the most amusing:

A patient came to consult him, and was at once overwhelmed with directions on the subject of the life he should lead and the diet to which he should adhere. "Now, remember, only one glass of wine at each meal," the physician concluded, "and just one cigar after dinner won't hurt you. Good-morning. Be sure you keep strictly to the one cigar."

"One cigar!" said the patient. "But——"

"My dear sir," broke in Sir Andrew, somewhat testily, "I must insist. If I am to treat you, you must follow my directions. I know quite well you will find it hard, but it is absolutely necessary for your health."

The patient heaved a deep sigh. "All right, Sir Andrew; since you insist I will do my best. Good-morning."

He went his way, but his health did not improve, and at the end of a few weeks he returned to the physician's consulting room.

"No better?" said the doctor, surprised. "But have you followed all my directions?"

"Absolutely," replied the visitor. "I must admit that the cigar was rather hard work at first, and in fact made me feel very ill; but I soon got used to it, and now I rather like it."

"Good heavens!" said Sir Andrew, on whom the truth dawned, "do you mean to tell me——"

"Yes, I had never smoked before."

Determination of Sex.—Dr. J. C. McAllister, of Driftwood, Pa., writes: "In a recent case coming under my observation, where the time of conception was definitely known to have taken place immediately after menstruation ceased, a well-developed female child was born on the two hundred and seventy-fourth day."

Who First Opened Woman for Diseases of Her Appendages?—Cullingworth, in his able address on gynecology before the British Medical Association, tells us that Hagar, Tait, and Battey performed resection for diseased ovaries at about the same time. It was in 1872, Hagar, on July 27th, did the first operation at Freiburg, for neuralgia of the ovary with hemorrhage. Five days later Lawson Tait removed the ovaries in a case of large uterine fibroid with excessive metrorrhagia. About three weeks after Hagar's operation, Battey, of Georgia, operated for hystero-epilepsy. Simms coined the term "Battey's Operation," because the latter first fully set forth its purposes and the technique of the operation.—*Gazette de Gynecologie.*

"**Anti-diphtherine**" is the name of a new remedy emanating from Professor Klebs, of Vienna, by which, it is stated, cases of diphtheria can be certainly "cured." The sanguine way in which reports of this nature are issued by the lay press is a feature of modern journalism.

Iodine Trichloride as a Hypodermic Injection in Puerperal Septicæmia.—Gottschalk publishes a note on the use of iodine trichloride in cases of puerperal fever. It has been asserted that this salt is so irritating that it cannot be used hypodermically. Gottschalk has employed it in three cases of puerperal fever, injecting it deeply into the gluteus muscle without any painful result. He used a one per cent. solution, of which from one to 2 c.cm. were injected once or twice daily. Two of the cases recovered.

The Physicians' Protective Association is the title of a society recently established in Detroit. It contemplates the collection of fees for professional services.

Why Physicians do not Share the Honors of the World.—With that ingenious acumen which so peculiarly distinguished him, Dr. Walter Moxon used to contend that the reason why the medical profession did not largely share in the "honors" of this world was that the physician and surgeon were concerned with units as opposed to the race. It could hardly be expected, there-

fore, that the race would reward the medical man as it rewards the politician, the lawyer, and the soldier, who act on behalf of the constitution, the State, and the country, and pay little regard to the individual in their respective avocations. It may be from some reason of this kind that medical men have not paid as much attention as might have been expected to general biological problems, feeling perhaps that the teachings of biology were often at variance with their efforts to preserve the individual.—*Medical Magazine.*

The Samuel D. Gross Prize.—The quinquennial prize of $1,000 under the will of the late Samuel D. Gross, M.D., will be awarded January 1, 1895. The conditions annexed by the testator are that the prize "Shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in Surgical Pathology or Surgical Practice, founded upon original investigations, the candidates for the prize to be American citizens." It is expressly stipulated that the successful competitor, who receives the prize, shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. The essays, which must be written by a single author in the English language, should be sent to Dr. J. Ewing Mears, 1429 Walnut Street, Philadelphia, before January 1, 1895. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. The Committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year. The Committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

A New Building for the Omaha Medical College, costing $20,000, was dedicated November 21st. Dr. H. B. Lowry, of Lincoln, Neb., delivered the opening and dedicatory address to a large audience.

Death of Dr. John Fussell, of Wheeling.—Dr. John Fussell, of Wheeling, O., died November 18th, aged seventy-eight. For nearly fifty years he was the leading practitioner of his vicinity, and was an active participant in all matters tending to advance sanitary and municipal reform.

The Use of Tobacco by Lunatics.—Some time ago we noticed the recent order of the Lunacy Commission of this State abolishing the use of tobacco in the Hudson River State Hospital at Poughkeepsie, on the plea that pipe smoking might occasion fire. While such dangers could be easily obviated, we cannot estimate the real amount of discomfort and suffering which may be occasioned to the helpless inmates who have used tobacco during the greater part of their lives. Very properly, protests against this absurd action are coming in from all quarters. As yet, however, the commission is autocratically silent.

More about Football.—The *New York Herald* publishes the detailed accounts of twenty-six deaths occurring so far in England during this season, directly attributable to football injuries. During the season of 1891–92 the number of deaths was twenty-two, and during 1890–91 there were twenty-three deaths. Mr. R. D. Paine, *New York World*, gives this account of the scholarly life of the football player: "More than two hours every day are now spent in signal practice. In the forenoon, the hour from 10 to 11 is passed on the floor of the big exercising hall of the gymnasium. The doors are locked and the eleven lines up against imaginary opponents. The coaches criticise the way the plays are put into effect, and the whole series of signals is gone through with again and again. The hard practice game takes from 2 until 4 in the afternoon, and it is 4.30 before the men are all sponged, rubbed down with alcohol by professional rubbers, and dressed. Supper at the training-tables comes at 6 o'clock, and from 7 to 8 comes signal practice again behind sealed doors in the gymnasium. This ends the day's work for the weary band. At 10 o'clock the force of rubbers starts out and every player is visited at his room, where, just before he tumbles into bed he is thoroughly rubbed and liniment applied to bruises and sprains. This is the daily life of a university football man through November. He has the rest of the year in which to catch up with his studies. He does not get very deep into learning while his hair is long and the canvas jacket the sign of his calling."

Bechterew has succeeded Mierzejewski in the chair of neurology and psychiatry in the Military Medical Academy of St. Petersburg.

Dr. John M. Keating, of Philadelphia, died of pneumonia, at Colorado Springs, on November 18th, whither he had gone some three years ago on account of failing health. He was the eldest son of Dr. William V. Keating, and was well and favorably known as an obstetrician, gynecologist, and pediatrist. He made a number of valuable contributions to medical literature and held a number of important positions in Philadelphia, where he was highly respected and esteemed. His system of children's diseases formed one of the best of American contributions to medical literature.

Boston Physicians find that acute poliomyelitis (infantile paralysis) was unusually prevalent during the past summer and fall.

Another Fatal Accident at football is reported, making six in all for the present season.

The Negro Physicians have an organ, the *Medical and Surgical Observer.* The medical ladies have an organ, also the railway surgeons, the Chinese, and the *Medical Mirror* asks why not red-headed men?

Virchow's Successor.—Professor Weinhold has been elected Rector of the University of Berlin to succeed Virchow, whose term ended at the beginning of the present semester. The new Rector at once appointed Virchow to be a member of the University Senate.

A Reception to Dr. Holmes.—The College Club of Boston gave a reception to Dr. Oliver Wendell Holmes last Saturday afternoon. Mrs. L. S. Davis, the president of the club, assisted by Mrs. Alice Freeman Palmer, received the guests. About five hundred persons were presented to Dr. Holmes, who received them seated in a laurel-decorated chair in the parlor, under a bower of palms. During the evening Dr. Holmes recited "The Last Leaf," "Dorothy Q," and "The Chambered Nautilus."

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 16, 1893.

D. B. St. John Roosa, M.D., President, in the Chair.

Myxœdema, Acquired and Congenital, and the Use of Thyroid Extracts.—Dr. George W. Crary read a paper on this subject. The pathology and etiology were touched upon briefly, as he said he had nothing new to offer in this direction. Greater space was given to symptoms and the results of treatment by thyroid extract. Myxœdema was a disease of all ages, but occurred oftenest in children and in women about the menopause. It might be well marked at birth. In adults the clinical picture was pretty uniform. In a typical case the facial expression was dull, the skin thick, the eyes partially closed, the lids heavy, the brows elevated because of the constant attempt to keep the lids raised, the forehead wrinkled, the nose broad, its base flattened, the lips thick, the mouth open, the tongue partially protruding, the chin double, the speech slow and indistinct, the hair fallen out, the skin dry, scaly, and wrinkled and spotted with chloasma, a hectic spot over the malar bones in strong contrast to the color of the rest of the skin, the mucous membranes pale, the skin over the whole body swollen but not pitting, contrasting in this regard with the œdema of Bright's disease. Vesicants had little effect. There was dysphagia, and the patient complained of changed sensations, like cold water was being poured down the back, etc. The patient was melancholic, but not as in ordinary melancholia. There was muscular weakness or lassitude. The temperature was apt to be below normal. The urine often contained the elements present in Bright's disease. The disease developed slowly, and the patients were better in summer than in winter.

In the congenital form the symptoms and peculiar appearance just described existed in exaggerated degree in consequence of interference with development. The patients might be of feeble intellect or idiotic, be epileptic, deaf-mutes, etc.

The greatest liability to err in diagnosis was in confounding the acquired form of myxœdema of adults with chronic Bright's disease, and in two of the cases which the author related that mistake had been previously made. But after one had seen cases of myxœdema the differential diagnosis was not difficult to make, especially after the early stage. The congenital form in infants bore some resemblance to rachitis, but the two conditions were not often confounded.

Treatment.—The treatment of myxœdema was by extract of the thyroid gland. One whose name would ever remain most closely associated with this method was G. R. Murray, of England. For a historical review the author referred to Dr. Kinnicutt's paper. The extract from the thyroid of the lamb had been found more efficient than that from the older sheep. It was efficient, whether administered subcutaneously or by the mouth. Where bad effects had followed they had been due to the use of too large doses. Among them were headache, nausea, vertigo, even convulsions. The effect of the treatment upon the disease was to cause the œdema to disappear, and to improve all the symptoms except the anæmia and rheumatoid pains. The urine tended to clear up; the quantity of the fluid and urea, together with the specific gravity, increased. Aude had pointed out that during the first two weeks the amount of nitrogen excreted exceeded that in the food. Where there had been failure it was not unlikely thymus instead of thyroid extract had been employed. In nearly all reported cases the symptoms had regularly disappeared after three or four weeks' use of the extract, but it was necessary to continue the remedy subsequently, though in smaller doses, in order to prevent a return of the symptoms. Dr. Crary had used the glycerine extract in all cases, twenty-four parts of gland tissue to one of glycerine. The preparation should be kept from the light and heat. In a suitable place it would keep for months without change. An ordinary dose for an adult was five drops three times a day, which might be increased to fifteen; in infants, one drop three times a day, increasing to six drops a day.

Among the four cases which the author had treated by this method a most striking one was that of a child suffering from congenital myxœdema with the appearance of marked symptoms the first year. He saw the child at the fifth year, when its development was only that of an infant. But little mentality was manifest, and the effort of turning over in bed caused prostration; the entire body was markedly œdematous, the face swollen, lips thick, eyes closed, nose flattened, tongue protruding, skin dry, etc. Within a few weeks after beginning treatment with the thyroid extract there was marked improvement, and within a few months there was an entire change in the appearance and in the bodily and mental condition. Measurements were taken and showed rapid decrease of circumference of legs, etc., from disappearance of œdema, but rapid increase in length of the extremities from physiological growth following the treatment. It was not improbable, he said, that many cases of backwardness or idiocy in children were due to myxœdema and could be improved or cured by the use of thyroid extract.

Lantern Exhibition of Photographs of Myxœdema Cases.—Dr. M. Allen Starr projected on the screen photographs of about half a dozen cases of myxœdema, showing the stages of development of the disease and the effects of treatment by thyroid extract. Two or three of the cases had occurred in his own practice and had been treated by Dr. Crary, with the results described in the paper. Dr. Starr had regarded the first two as cases of Bright's disease until his attention was called to myxœdema, when the diagnosis was corrected, thyroid treatment was begun, and the patients were cured except for the persistence of anæmia and some rheumatic pains. He believed many inmates of asylums and many persons supposed to be suffering from Bright's disease were really afflicted with myxœdema and could be improved in a most striking manner by the use of thyroid extract. The melancholia in these cases was different from ordinary melancholia, and the dementia was different from ordinary dementia, whether primary or secondary.

A Great Discovery.—Dr. W. Gilman Thompson regarded the discovery of the therapeutical effect of thyroid extract in myxœdema as one of the greatest in the history of medicine. Little had been known of the function of the thyroid gland further than the effect of its removal in animals larger than birds and rabbits. Those effects were—tremor, muscular paresis, stupid mental condition, lowering of bodily nutrition, etc. Occasionally, however, the health of the animal was maintained. He had had a case of myxœdema of twelve years' duration, in which the beneficial results from a short course of treatment by the thyroid extract were most marked. It was usual for the hair to return, and he had heard of one instance in which it had been gray, and when it returned after treatment it was almost black.

Drs. Kinnicutt, Draper, and Kinnear each related cases treated successfully by the thyroid extract, and some further remarks were made by Drs. Brannan, Berg, and Crary.

To Change the Coroner System.—The committee, consisting of Drs. Girdner, Armstrong, and A. Jacobi, appointed at the last meeting to draw up resolutions regarding a change in the coroner system, reported the following, which were adopted, Dr. Berg alone opposing them, on the ground that the Academy should let politics alone, and also on the ground that the Massachusetts system was not known to most of the members, and was not as good as that in either Paris or Berlin:

Whereas, The prerogative and duty of the coroner,

among other things, is to investigate the cause of death from violence, and of death occurring under suspicious circumstances, also the cause of death of a person that died without the attendance of a legal practitioner or within twenty-four hours after the first visit of a legal practitioner who declared himself unable to make a diagnosis and to testify to the cause of death, and finally the cause of death in a premature or still birth, no matter whether foul play be suspected or not, provided there be no satisfactory death certificate by a legal practitioner;

And *whereas* the investigation of these obscure cases is beset with great difficulties, requires very much more than the knowledge and information of the average physician, otherwise fully equipped for the practice of medicine, demands indeed a very minute knowledge of general medicine and surgery, and particularly of pathology and toxicology;

And *whereas*, under existing laws the ferreting out of a criminal case is expected from a coroner, who need not be either a police officer or a lawyer or a physician, but who, knowing that the cause of death can be elucidated only by the application of medical science and art to the individual case, has to select a medical man as his deputy officer;

And *whereas* experience teaches that these deputies have frequently been selected either for their party allegiance or for personal reasons, and are often young men with no reputation for unusual skill, learning, or practical experience, and have not had an opportunity of giving public assurance of their character, integrity, and wisdom. It also teaches that the final verdict in a criminal case depends upon the finding of this deputy, who, under other circumstances, would not be accepted as an expert; on the summing up of a coroner, whose untaught mind cannot satisfy the claims of justice, and finally, on a jury gathered at random, without regard to standing, character, morals, intellect, or knowledge; be it

Resolved, by the New York Academy of Medicine, That a medical man of mature years, established character, broad mind, and sound and extensive information in anatomy, pathology, toxicology, and all the other branches of forensic medicine must be the responsible occupant of an office in whose keeping are the most sacred interests of the individual and of the community, and to him should be delegated the initiative and power to elaborate the investigations of an actual or alleged criminal act, his conclusions being reported to the office of the District Attorney; and be it

Resolved, That the New York Academy of Medicine earnestly calls the attention of the approaching Constitutional Convention to the admirable system of medical examiners which the State of Massachusetts has substituted for the coroners' system, and the Academy urges the enactment of similar laws in this State; and be it further

Resolved, That copies of this resolution be forwarded to the various county, local, and special medical organizations in this State, with the request that they lend their co-operation to secure the necessary changes in the constitution and laws of the State of New York.

The New York Infant Asylum Affair.—Dr. John Wyeth spoke as follows:

The subject I am about to introduce is unfortunately not new to the profession of this city. I do not know whether it has ever been brought before the Academy for official action or not. Within a few months a reputable physician, a member of the Academy, one of the visiting staff of the New York Infant Asylum, after years of faithful service, was, by the President of the Board of Managers, dismissed from the service and another physician appointed to fill his place.

No charges of any character were preferred against this physician. There was no question as to his qualification for, and his faithful performance of, his duties. The Medical Board, which is held responsible for the welfare of the inmates of this institution, was not consulted, either as to the dismissal of this gentleman or the appointment of his successor. The Medical Board, with becoming dignity and self-respect, protested against this action of the managers, and being informed that if they did not like it they could resign, they did resign.

I am not one of those who believe in the infallibility of the medical profession. On the contrary, I think they are very fallible and very often wrong, especially in their proneness to suspect an affront to their position or calling when none is intended.

I think the gentlemen of the laity who devote their time and money to the support and management of these great charities, in connection with which so many of us labor, are deserving of the utmost praise and consideration and are not second in unselfishness to ourselves.

But I do think that in this particular instance an honorable and devoted medical staff have been treated with such disrespect as to amount to an insult to themselves, to the profession in which they have had honorable careers, and that we as a body should resent it.

I hold that a principle is at stake, a principle which it is necessary to maintain, not only for our standing in this community (and this I consider of secondary importance), but for the best interests of that unfortunate class, the poor and helpless patients who come under our professional care at the hospitals. That principle is involved in the following resolution of the resigning board:

Whereas, The Medical Board of the New York Infant Asylum respectfully requested the Board of Managers: 1. No faithful medical officer shall be removed without cause. 2. Nominations to fill vacancies shall emanate from the Medical Board.

Whereas, These reasonable and just demands have been peremptorily refused by the Board of Managers.

Resolved, That in dignified protest and in justice to themselves as men and physicians, the following members of the Medical Board hereby resign.

In view of this I offer the following resolution:

Resolved, That the New York Academy of Medicine endorses the resolutions and the action of the physicians who resigned from the New York Infant Asylum, and joins in their protest against the unjust and unwise action of the Board of Managers.

Dr. Wyeth's resolution excited a warm and lengthy debate, during which several speakers spoke in opposition to the Academy taking action in this case because it would set a precedent for bringing before it in the future special cases of abuse of authority on the part of managing boards of hospitals, etc. Moreover, Dr. Bradley, as member of the Medical Board of the New York Infant Asylum, claimed that the action of the Medical Board was illegal as not a full quorum was present at the time the protest was made.

Dr. H. D. Nicoll, a member of the Board of Managers, said:

Nine years ago, a majority of the Board of Managers of the New York Infant Asylum, being dissatisfied with the members of the Medical Committee, changed the by-laws so as to place the entire medical management of the asylum absolutely under the control of the Board of Managers.

The following by laws were adopted, viz.:

"Article III.—Committees.

"Section 1. The Board shall appoint, annually, the following Standing Committees, viz.: an Executive Committee, a Finance Committee, an Auditing Committee, a Medical Board. . . .

"Section 5. The Medical Board shall consist of not less than five members, none of whom shall be managers, whose duty it shall be to supervise the sanitary condition of the Asylum, and the health of the inmates, under the direction of the Board, and perform such other duties as may be assigned them by the Board.

"Article V.—Physicians.

"Section 1. Visiting, Resident, and Consulting Physicians and Surgeons shall be appointed annually by the

Board, to be known as the Medical Board. Their duties shall be such as may be from time to time fixed by the Board.

"SECTION 2. The Board shall also appoint a Curator and Pathologist on such Medical Board, and such other officials in the Medical or Sanitary Department as it may deem for the best interests of the Asylum."

The original members of the present Medical Board, appointed nine years ago, took office after the above by-laws had been adopted, and, as far as my knowledge goes, did so without taking exception to the restrictions so plainly expressed in them, although these appointments had been declined by such members of the profession as Drs. Fordyce Barker, T. M. Markoe, John T. Metcalfe, Lewis A. Sayre, T. G. Thomas, and W. T. Lusk, because they were unwilling to serve under such rules, and each new medical staff since that time has, annually, accepted the appointments without complaint.

I am informed by the President of the Board of Managers that the Board has repeatedly exercised its rights in the matters covered by these by-laws. In making the medical appointments for the current year, the managers exercised this right. To this the Medical Board took exception in a series of resolutions sent to the Board of Managers, among which were these, viz.:

Resolved further, That the following statement of grievances be incorporated for the information of individual members of the Board of Managers:

1. A faithful medical officer has been removed without cause or explanation.

2. Appointments on the consulting and visiting staff have been made by the Board of Managers, without the knowledge or recommendation of the Medical Board, as has been customary in the past, and is the rule in other medical institutions.

Resolved further, That the Medical Board respectfully suggests, without desiring to interfere with the prerogatives of the Board of Managers, that:

1. No member of the Visiting or Consulting Staff be removed without cause or explanation.

2. That nominations on the Visiting and Consulting Staff emanate from the Medical Board.

To these resolutions the Managers replied as follows:

Resolved, As the sense of the Board of Managers:

1. That, as the members of the Medical Board and Medical Staff are appointed annually by the Board of Managers, their term of office is for one year only.

2. That it would be opposed to the spirit and intent of the by-laws, and contrary to the usages of this Institution, for the Board of Managers to feel compelled, in making their annual appointments, to consult the Medical Board, whose terms of office had expired, as to who should compose the Medical Board and Medical Staff for the ensuing year.

3. That changes in the annual selection of members of the Medical Board and Medical Staff cannot be properly construed as a removal of any previous members who may not be included in such selection; nor as any reflection upon them personally, upon their professional standing, or upon their past services to the Institution.

4. That this Board regrets that certain members of the Medical Board have felt themselves justified in reflecting upon the President of the Institution in a communication addressed to individual members of this Board personally.

5. That in the judgment of this Board the communication referred to was signed by members of the Medical Board under a misapprehension of the facts and of the relation of the Medical Board to the Board of Managers.

6. That the Secretary be directed to transmit a copy of these resolutions to the Medical Board.

The Managers believe that their resolution 3 was a satisfactory reply to the first "grievance," and that their resolution 2 fully covered the point of the second "grievance," as the members of the Medical Board have for nine years been living under the rules as they now exist. The Managers were unable to see how they could adopt the suggestions of the final resolution of the Medical Board without interfering "with the prerogatives of the Board of Managers," which the resolution expressly stated the Medical Board desired not to do.

Dr. Nicoll then read the following letter from Dr. Thomas:

"DEAR DR. NICOLL: I think that the Board of Managers of the New York Infant Asylum is to be arraigned at the Academy of Medicine to-night, and as I cannot attend, I write you this to be used by you in case any good can come from it. To save time and avoid prolixity I make my statement *seriatim*.

"1. About nine years ago I was offered the post of Consulting Gynecologist in the New York Infant Asylum and refused it, because I was unwilling to serve under the very objectionable by-laws passed by the Board of Managers. I was amazed to find that some of my colleagues were willing to wear a yoke which appeared oppressive to me.

"2. About a year ago you called upon me, expressed yourself as utterly dissatisfied with these by-laws, which you characterized as being humiliating to our profession, and asked me to become a manager in order to alter and improve them. Your hope at that time was to retain the existing Staff, and to free them from unworthy restrictions. Although very averse to doing so I yielded to your reiterated wishes and became a manager.

"3. Since that time I have had one special object in view, namely, the accomplishment of the purpose for which I joined the Governing Board of the Institution, and success would have met our efforts ere this had not the unwise and illogical action of a part of the Medical Board frustrated them.

"4. I appeal to my record of forty years in medicine in this city to sustain the assertion that no one has more consistently stood up for the dignity and honor of our profession than I, and supported by this, I declare that but one thing suggests itself as capable of defeating the object which I, as well as yourself, have in view; that is, some injudicious action taken to night which will deprive us of all influence and paralyze our best-directed efforts.

"I am, dear Doctor, sincerely your friend,

"T. GAILLARD THOMAS.

"November 16, 1893."

Dr. Nicoll, in conclusion, hoped the Academy would not adopt the resolutions, as it would make it impossible for them to effect the reform which they seemed on the eve of accomplishing.

The resolutions were finally laid on the table.

Proposed Changes in the By-laws.—DR. S. T. ARMSTRONG proposed some changes in the by-laws, one of which was: No section is authorized to institute any procedure that is of a public character without first submitting the subject for the consideration and approval of the Academy.

Black Urine.—Derivates of biliary pigment in the urine may simulate melanin. It cannot, therefore, be concluded that a melanotic tumor exists if the urine reacts to chromic acid. All melanotic tumors are not attended with elimination of melanin in the urine. It should be borne in mind that the urine of patients with melanotic tumors may contain melanin, and yet not react to chromic acid.—SENATOR.

Frank Advertising.—A method of offering commissions to physicians adopted by a Philadelphia firm of manufacturers and dealers in trusses is unequivocal. Blotting-pads are sent all physicians (even oculists!) praising the trusses, the "lady attendant," etc., but the most emphasized part of the advertisement is this, in double caps: "IF YOU WILL SEND US YOUR PATIENTS WE WILL RECIPROCATE WITH A CHECK BY RETURN MAIL." This is a notice to the traders in medicine, but it is also a notice to physicians where *not* to send patients.—*Medical News.*

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Sixth Annual Meeting, Held in New Orleans, La., November 14, 15, and 16, 1893.

FIRST DAY, TUESDAY, NOVEMBER 14TH—MORNING SESSION.

THE Association convened in the assembly room of the Medical Department of Tulane University, and was called to order by the President, DR. BEDFORD BROWN, of Alexandria, Va., at 10 A.M.

Prayer was offered by the REV. B. M. PALMER, of New Orleans.

An Address of Welcome was delivered by DR. ERNEST S. LEWIS on behalf of the local profession, which was responded to by PRESIDENT BROWN.

DR. A. B. MILES, of New Orleans, then reported, as chairman, on behalf of the Committee of Arrangements. The reading of papers was then proceeded with, and the first paper read was by DR. HOWARD A. KELLY, of Baltimore.

Diagnosis of Pelvic Inflammatory Diseases.—Dr. Kelly called attention to certain common sources of error in making diagnoses of pelvic inflammation. An erroneous conclusion is often reached in these cases, both by general practitioner and specialist, by relying for the diagnosis upon such symptoms as dysmenorrhœa, more or less persistent pain in the pelvis, attacks of pain confining the patient to bed, diagnosed as peritonitis, difficult locomotion, cachexia (due to morphia habit), tenderness on pressure over the ovarian region, and extreme tenderness at the vault in a vaginal examination. Such a group of symptoms frequently characterizes a false or pseudo-pelvic peritonitis, in which there is actually no demonstrable lesion of any pelvic organ.

In order to make a diagnosis of true pelvic inflammatory disease the inflamed structures must be examined directly by touch. The various subjective symptoms must be regarded as of secondary importance in reaching a diagnosis. Even the patient's observation that she has passed a quantity of pus cannot be relied upon, unless the pus is seen by the physician, as patients often mistake muco purulent discharges from the uterus for the emptying of an abscess.

Fever, and especially recurrent attacks of fever, are valuable aids in making the diagnosis, but fever is generally absent, even in abscesses when the pus is encapsulated. The direct examination, the sole test, is made by the vagina, or by the vagina and lower abdominal wall, and the diagnosis of pelvic inflammatory disease is made when a definite hard resisting mass is felt on one or both sides of the cervix. Through an empty rectum these masses are still more distinctly outlined. When the disease is not quite so evident a bimanual examination through the rectum and abdomen should be made, carrying the index-finger of the lower hand above the rectal pouch behind the uterus, and laterally out on to the broad ligaments. The most minutely accurate examination of the pelvic organs which can possibly be made is called for when the ovaries and tubes are enclosed in delicate bands of adhesions which allow considerable mobility to structures not enlarged. This is accomplished by the trimanual method of vagina, rectum, and abdomen simultaneously, under anæsthesia.

Dr. Kelly exhibited his corrugated tenaculum devised to facilitate this examination. The point of the tenaculum is caught in the anterior lip of the cervix, which is drawn down to the hymen, and the tenaculum is held between the third and fourth fingers and the ball of the thumb, while the index-finger is introduced into the rectum and, aided by the hand-making pressure above giving a plane of resistance, is enabled to examine minutely the posterior surface of the uterus, and all surfaces of the ovaries and the tubes, detecting the slightest adhesions binding these organs down. The examination under anæsthesia is a matter of the utmost importance, and not sufficiently appreciated. Without anæsthesia the most accurate examinations are impossible, it is therefore a *sine qua non* to the diagnostician.

The Conservative Treatment of Pyosalpinx.—DR. C. KOLLOCK, of Cheraw, S. C., followed with a paper on this subject. He said, in cases of pyosalpinx, much caution and a very careful and rigid examination are called for to determine the cause of the presence of pus, the length of time it has been there, and the condition of the walls of the tube in which it is found. Attention should also be given to the peritoneum and ovaries, but above all, there should be the strictest inspection of the endometrium, a disordered condition of which contributes much to the production and continuance of pus in the tubes.

Within a year or two changes have been made in the treatment of pyosalpinx, and conservatism now enters largely into its management. Men of high position in the profession are more decidedly agreed that a moral obligation rests upon us to relieve patients without the sacrifice of any organ, or part of one, when this is compatible with safety. Recently Polk, Pryor, Krug, Boldt, and Dudley had reported to the New York Obstetrical Society a number of cases of pyosalpinx treated by the conservative method now in vogue. This treatment, when faithfully carried out by curettement and aseptic divulsion, has not only been successful in saving the tube and ovary on the non-affected side, but in several instances the diseased tube was entirely relieved of the presence of pus. That many cases of pyosalpinx have been accurately diagnosticated and radically cured without the mutilation of any part of the sexual organs, is well authenticated. Dr. Kollock's experience, while limited compared to that of others, has been sufficient to convince him that the conservative system of practice is bringing us to that period when the mutilation of women, once supposed to be necessary, should cease.

Dr. Kollock then reported a few cases of pyosalpinx which had fallen into his hands, the happy termination of which had placed him under obligations to the pioneers in the conservative treatment. All but one of four cases were relieved entirely without resorting to cœliotomy.

DR. GEORGE J. ENGELMANN, of St. Louis, Mo., emphasized the importance of administering an anæsthetic in examining patients with pelvic inflammatory disease, before serious operative procedures are entered upon. It was not alone the anæsthetic, however, but the practised touch.

DR. JOSEPH PRICE, of Philadelphia, Pa., alluded to "dropsical tubes" as being a group of cases that puzzled the practitioner from a diagnostic point of view, and later surgically. Angry pus cases, while acute in their early history, were simply cases to be dealt with surgically. The attacks of pain were numerous, and fixation and tenderness characteristic symptoms. Everything in the pelvis was board-like, and when the surgeon got into the abdomen from above it was difficult to distinguish the uterus from the appendages, and *vice versa.* These were trying cases to deal with.

DR. JOHN D. S. DAVIS, of Birmingham, Ala., said he was in favor of evacuating pus wherever it was found in the body. There were, however, some cases in which pus could be removed without sacrificing the ovaries or tubes. As to the use of an anæsthetic, he considers it absolutely essential in the examination of doubtful cases, but where the diagnosis is plain it is not necessary.

DR. R. B. MAURY, of Memphis, said the great difficulty in the class of cases referred to by Dr. Kollock, in which there was pelvic inflammation associated with muco-purulent discharges from the uterine cavity, was to decide whether there is pyosalpinx. We have what is denominated endometritis, associated with it normal discharges and exudation in the pelvis, but Dr. Maury says he is at a loss sometimes, with the most careful diagnostic measures, whether under ether or without it, to form in his own mind an accurate picture of what the precise state of

things is in the pelvis. The rule he has laid down in the treatment of such cases is, if they are acute, non-puerperal, or puerperal, that the woman is entitled to a certain period of rest and other measures non-surgical, before deciding upon a radical operation.

Dr. W. E. B. Davis, of Birmingham, Ala., believes that, in the examination of patients, it is exceedingly difficult in some cases to make an accurate diagnosis without an anæsthetic. However, there were women who could stand the examination well without it.

In regard to endometritis, by judicious and careful curettement he believes many patients can be saved the necessity of an abdominal section. The trouble is that practitioners often denounce one procedure and uphold another without outlining the indications for a certain position. It is very important to cure the endometritis before it spreads to the tubes, etc.

Dr. R. M. Cunningham, of Pratt City, Ala., was inclined to look upon endometritis, in the vast majority of cases of disease of the appendages, as the *fons et origo* of the whole affair, and he believes that the operation which has been systematized and popularized by Dr. Polk is a safe, conservative, and reliable procedure. Furthermore, in the hands of the general practitioner it would relieve many of those cases that go to the laparotomist.

Dr. Bedford Brown, of Alexandria, Va., said the mobility of the uterus and its fixations were questions of great importance in diagnosticating pelvic inflammatory disease.

Dr. L. S. McMurtry, of Louisville, Ky., delivered a memorial address on Dr. Ephraim McDowell. He said it would seem almost a work of supererogation to submit an elaborate biographical sketch of McDowell, after the very complete accounts of his life and labors which have been contributed to medical literature by the late Professor Samuel D. Gross and the late Dr. John D. Jackson; yet, he presumed that no one would for a moment question the good taste and wisdom of perpetuating in the volumes of "Transactions of the Association" the names and deeds of eminent Southern surgeons who had done so much to lay the foundation, in America and the whole world, for the present splendid system of surgery and gynecology. This galaxy of illustrious names would be incomplete without that of McDowell, the father of ovariotomy and the pioneer of abdominal surgery, which in modern times has grown to such grand proportions.

In the year 1852, twenty-two years after the death of McDowell, Professor Gross, in his celebrated report on Kentucky surgery to the Kentucky State Medical Society, presented a sketch of the life of this eminent surgeon, with a detailed account of his original surgical work. This sketch was subsequently incorporated in Gross's "American Medical Biography," published in 1861.

After giving a sketch of his life, Dr. McMurtry then referred to McDowell's first ovariotomy, on Mrs. Crawford, and noted some points with reference to his operative technique. The operation in this case was done without an anæsthetic. The incision was made to the left of the median line, about three inches external to the rectus muscle, and was nine inches in length. After opening the peritoneum he first tied the pedicle with a strong ligature, and then cut open the tumor and removed its contents. He then divided the pedicle, it having been previously tied, and removed the sac. As soon as the incision was made into the abdomen, he states the intestines rushed out upon the table, and were not replaced until the operation was completed, which, he adds, "occupied twenty-five minutes." He then turned the patient upon the left side to allow all fluids to escape. He closed the incision with interrupted sutures and brought out the ligature attached to the pedicle at the lower angle of the wound.

In reporting his cases he omits mention of the material composing the ligature, and Dr. McMurtry had been informed by a friend of McDowell, now dead, who was a great deal about McDowell's office in his boyhood, that the ligatures used were made of shoemaker's thread and waxed thoroughly before being used. Adhesive strips and bandages completed the dressing, and in the author's language, he prescribed "a strict observation of the antiphlogistic regimen." The special features of the technique are: 1. The incision was made through the muscular layer of the abdominal wall, three inches external to the rectus muscle. 2. The cyst was not evacuated until after the pedicle was tied. 3. An effort was made to cleanse the peritoneum of fluids. 4. Drainage was sought, as well as escape of ligatures, by bringing the ligatures out at the lower angle of the incision. 5. The operation occupied only twenty-five minutes, expedition being more the result, doubtless, of the want of an anæsthetic than otherwise.

In his report of his second case he used this language: "I laid her side open." In his third case, however, he adopted the median incision, saying in his report of this case, "I changed my place of opening to the linea alba." In all of his cases he ligatured the pedicle before separating the adhesions or tapping the tumor. In his third case he mentions that the ligatures could not be released for five weeks, at the end of which time the cord was taken away.

Afternoon Session.

The Incision in Abdominal Section—How to Close It—Post operative Complications about It.—Dr. Joseph Price, of Philadelphia, read a paper on this subject. He said the question that most vitally concerns surgical and gynecological work was, How can the mortality be reduced? Surgical judgment and surgical fingers repeatedly determine the issue of life or death.

The Incision.—We have nothing from which we can ever approximately determine to what extent the length of the incision influences the mortality. The statistics of comparative results would not prove satisfactory, for the reason of the entry of so many other compromising elements—adhesions, their character, extent, and locality. That the incision exercises a greater influence than is generally recognized or admitted, he entertained little doubt. As to length, no rule of mathematical certainty could be laid down. In his own experience he finds the balance of both convenience and safety to lie with the short incision. The short incision narrows the limits of hemorrhage. It is safe to begin with a small incision, and where the size and character of the tumor or complications present require a larger one, it can easily be made. Very much abdominal work can be done through an opening admitting only two fingers. The reliance of the abdominal surgeon must be largely in educated fingers. In the majority of cases an operation can be done through a small incision without the operator or spectators seeing viscera. Universally adherent, irreducible, or solid tumors require a long incision for delivery, and for dealing with complications that can only be dealt with through a long incision, those beneath and on the sides of tumors. In the majority of cases, to so enlarge the opening as to obtain a view of the parts, we augment the risk of ventral hernia and provoke tedious convalescence.

The importance of a perfect closure of the incision has only recently received that attention it deserves. The effort should be to approximate as nearly as possible normal conditions, anticipating and dealing with all existing or possible complications with scrupulous minuteness and care, thus guarding against those accidents which are too frequent. He would not pretend to suggest uniform procedures to be carried out in all cases, as each operator has his own way and does his own work best that way, and it would not be possible for him to apply the methods of others safely and successfully without special training. He is satisfied that the exposure and manipulation of the incision, as well as the peritoneum, is harmful. Incisions bathed in pus and filth, and freely manipulated, often refuse to unite. Suppurating wounds are largely due to careless closure or to tight sutures, including too much tissue. Tight suturing is too common, and has

destroyed life in many feeble subjects. Suppuration due to tight suturing and stitch-hole abscesses, in all sections, where they do not result fatally, prolong convalescence. Cases were cited in point.

Through and through suturing including all structures, more of the central structure than skin or peritoneum, with either silkworm gut or pure silk, give and continue to give, the most satisfactory results. Silkworm gut seems to be the favorite material at present, as it possesses all the natural and essential qualities of a suture, is small, strong, and non-irritating—the three cardinal virtues of all good suturing material. Terracing sutures has nothing to recommend it; on the other hand, Dr. Price believes it prolongs an operation. Retraction of skin and peritoneum by the introduction of silkworm sutures, gives inclusion to more central structures and the least possible tension on skin and peritoneum. Keith, Tait, and Bantock, all use a fine straight needle, and their work has been about perfect. The use of large, curved, cutting needles is harmful, their use primarily favors hemorrhage, and secondarily stitch-hole abscesses.

Dr. Kelly thinks that long incisions have little or nothing to do with mortality, except in an indirect way. Where there are many adhesions a long incision is necessary. Handling of the viscera in pre antiseptic days increased the chances of suppuration, and consequently of peritonitis and death. The chances of infection he believes are greater with a long incision. Hernia comes from improper closure of the abdominal wall, or the use of the drainage-tube weakening the abdominal wall at one of its points.

Dr. L. S. McMurtry, of Louisville, demonstrated his method of suturing on the board. He brings peritoneum to peritoneum, muscular structure to muscular structure, fascia to fascia, skin to skin, and says the least quantity of interposing material we have between the tissues that are to be brought together the better. He disagrees with Dr. Kelly that the drainage-tube is the cause of hernia after closing the incision.

Dr. R. B. Maury, of Memphis, favored the silkworm gut through and through suture. His experience covers nearly three hundred sections, and he has simply used the through and through suture. He has had almost no abscesses and the fewest possible number of herniæ, and which he says can be counted on the fingers of one hand.

Dr. T. J. Crofford, of Memphis, said it was considered that all herniæ resulting from abdominal section were due to failure to get union between the opposing layers of transversalis fascia. He uses a long curved needle instead of a straight one. With it he can put in stitches in one-third of the time he can with the ordinary needle. He has used it in upward of two hundred sections, and has not had a case of hernia to follow one of them. He has also had the fewest number of stitch abscesses.

Dr. Price, in closing, said there was an immense amount of theory about the matter of long and short incisions, and there was a tendency on the part of some to brush aside pre-antiseptic work. Notwithstanding this, however, some of the old back-numbers, or hayseeds so called, had as good results in their day as are obtained in some of our hospitals to-day. He urged great caution in the terracing method of suturing.

Is Operation Demanded in all Cases of Appendicitis? The Best Time to Operate.—This paper was read by Dr. A. M. Cartledge, of Louisville, Ky. He said that inflammatory conditions of the appendix are essentially intra-peritoneal lesions. Modern surgeons have an abiding faith in the surgical maxim that whenever pus is believed to be present in tissues or organs of the body, it should be removed; hence the new pathology of a very old and frequently fatal malady inspired surgeons to attempt some radical means of relief. Perfection in technique can only come from individual experience and a knowledge of the work of others.

The pathology of a disease is the only true key-note to its rational treatment. Probably the best classification of appendicitis is: catarrhal (simple); ulcerative (from tuberculosis from foreign bodies); perforating (from ulcerative perforation from strangulation, the result of twisting). This classification deals strictly with the changes occurring in the appendix, and should be considered apart from the peritoneal and other conditions which may ensue and cause well-marked variations in the clinical course of the disease. If the walls of the appendix give way in a mass of fibrous adhesions, the result of long-continued irritation, the pus which forms is rather securely encapsulated and may be days, weeks, even years finding an outlet. In fact, as is often the case, if the bacillus coli communis predominates and a few staphylococci are present, it may remain encapsulated unless it receives a new impetus of irritation. Cases were reported illustrating this point. Cases were also reported illustrating the part played by injury as an exciting cause in appendicitis, and the belief was expressed that a chronic form of unrecognized appendicitis existed prior to such injury.

We know more about the pathology of ulcerative or suppurative appendicitis than we do of the catarrhal form, because the cases not operated upon which recover are mostly called catarrhal. These are cases which progress with little pain, with very little fever, 101° F. as a maximum, and have a tumor which subsides. These cases are the pride of the poultice and the opium practitioner. Ulcerative appendicitis must be either tuberculous or traumatic, the trauma consisting of foreign bodies and enteroliths, usually the latter. The tuberculous would only give rise to acute symptoms as the result of cicatrization and stenosis, with distal distention, or secondary inflammation with pus organisms. Either of these results favor perforation. This is essentially the chronic variety, but will eventually lead to perforation, probably in the ways indicated.

When physicians come to view inflammations of the vermiform appendix in their proper light, the author said, the prognosis will assume a very different shade. We should consider any appendix once so affected as to deserve the name of appendicitis, whether from tubercle or trauma, a lastingly diseased structure, and the fancied cures are quiescent states the results of very easily recognized conditions. If we could trace our so-called first-attack cases of appendicitis through subsequent ones, we would say the progress, not only as to health and comfort, but as to life, is bad, very bad. A man has the trouble three, four, or five times, apparently recovers—all counted as cures probably by different physicians. Finally he dies in an attack; the death is counted but once, and sometimes not then; for if, as is often the case, death results from the rupture of an unrecognized appendicial abscess, or from diffuse peritonitis after perforation, the chances are that the cause is never suspected, and death is recorded as occurring from peritonitis. Every case of appendicitis, not barred by surgical limitation, should be operated upon. The best time, provided the symptoms are not too urgent, is after the bowels have been thoroughly moved.

Dr. Joseph Price agreed with the author of the paper that there was but one treatment for appendicitis, namely, removal of the appendix. He considers it a murderous disease, to be classed with extra uterine pregnancy. Both demanded prompt surgical treatment when first discovered. He recommends, in acute cases of appendicitis without pus, removal of the appendix and freeing of the inflammatory adhesions.

Dr. G. W. Long, of Richmond, opposed operation in every case of appendicitis. Autopsies had shown that one-third of the human race had at some period of their lives had this disease. That being true, and considering the small per cent. of deaths, it naturally follows that appendicitis does not always kill, even if it is not operated on. In the catarrhal form, he thinks there is no reason for operating. In the perforative form we should operate. In the perforative form without adhesions we should also operate as soon as we make a diagnosis.

Dr. William T. Briggs, of Nashville, had been operating on every case of appendicitis that came into his hands where the diagnosis was clearly established, and he has had no occasion to regret it. He has operated in cases where there were perforative symptoms, and in others where there were none; in some where there were, and in others where there were not, suppuration, and still others where there was, and where there was not, sloughing.

Dr. C. Kollock, of Cheraw, S. C., had seen a great many cases of appendicitis. He recommends saline treatment in the first attack, but if there is a recurrence he invariably operates, and has never lost a case.

Dr. W. E. B. Davis, of Birmingham, Ala., had never operated on one of these cases without advising a secondary operation for removal of the appendix, telling the patient that the disease would recur. He thought, however, there were many cases that got well without operation, but it was a difficult matter to tell in what cases we should not operate.

Dr. Hunter McGuire, of Richmond, said he had many a time operated too late, but never in his life had he operated too soon. If, after free and full purgation with salts, administered by the mouth and rectum, the symptoms are not relieved, he thinks the time for operation has come, and does not hesitate to operate. He had never known the mere operation in the hands of skilful surgeons to kill or add to the danger of the patient's life. Appendicitis kills, and it is put down to inflammation of the bowels, peritonitis, or something else.

Dr. Louis McLane Tiffany, of Baltimore, said that the cases that require consultation should be divided into those that are going to live without bursting, and those that will rupture inside of three days, and then next to the question of making the diagnosis was to get the consent of the family physician. The cases that are dangerous die within seventy-two hours, before the family physician is able to make a diagnosis.

Dr. Willis F. Westmoreland, of Atlanta, favored early operative interference. He had never been called in sufficiently early by the general practitioner to operate, consequently the patients died promptly. It was necessary to educate the general practitioner to send cases to the surgeon for operation earlier.

Dr. W. B. Rogers, of Memphis, had seen cases of catarrhal, ulcerative, and gangrenous appendicitis, but had never been able to make a diagnosis until he got inside. The symptoms of the disease were the same as those of peritonitis, localized at the site of the appendix. In the cases he had operated on, he was satisfied that no medicine would have effected a cure.

Dr. Cunningham agreed with Dr. McGuire, that an operation should be done in case medical treatment failed to afford relief.

Dr. Riggs, of Birmingham, advocates operation in the recurrent form of the disease during the interval of attacks.

Dr. James A. Goggans, of Alexander City, Ala., had operated early on seven cases, all recovered.

Second Day, Wednesday, November 22d—Morning Session.

Intra-cranial Neurectomy, and Removal of the Gasserian Ganglion for Intractable Neuralgia, with Report of Cases.—Dr. Louis McLane Tiffany, of Baltimore, read a paper with this title. Within the past few years intra-cranial excision of portions of the fifth nerve, together with removal more or less complete of the Gasserian ganglion, has been done for the cure of intractable trigeminal neuralgia. The credit of first doing such an operation rests with Rose, of London, after whom is to be mentioned Novaro, Horsley, Andrews, and others. Dr. Tiffany then gave an account of Hartley's method, which appears in the *Annals of Surgery* for May, 1893.

It has been Dr. Tiffany's fortune to operate four times for excision of intra-cranial portions of the fifth nerve. In each case the reason for the operation was trigeminal neuralgia not due to disease of the brain. Hartley's method was followed. All cases recovered from the operation and were relieved of neuralgia, it is to be hoped, permanently. The operations have been long, but recovery in each instance has been rapid and complete. In all cases the wounds healed at once, except in the fourth case, where the patient scratched the recent wound and infected it.

It is worthy of note, that in the case of the patient upon whom operation was performed fourteen months ago, there is less anæsthesia and more perverted sensation than in the other cases. Sensation seems to have returned somewhat, and it is interesting to speculate as to whether sensation will ever completely return, and if so, by what route. Preservation of the sense of taste after division of the second and third divisions is to be noted. That the power to recognize heat and cold exists in a region rendered devoid of ordinary sensation by nerve section, is of much interest, and recalls an observation made some time since, that a conjunctiva insensitive from the local application of cocaine still appreciates the difference between heat and cold.

When dividing the third division of the nerve in case four, Dr. Tiffany believes that he isolated and recognized the motor branch before dividing it. Not having provided himself with a sufficiently long and fine electrode, he could not prove the accuracy of his opinion by electric stimulation, and therefore divided everything. By leaving intact the motor branch, the patient would not have food collect in the cheek of the paralyzed side, and in future operations an effort should be made toward this end.

The Vaginal Route as Compared with the Abdominal for the Removal of Pelvic Viscera.—By Dr. George J. Engelmann, of St. Louis, Mo. He called attention to the advantages offered by the vaginal route for many of the operations, and especially some of the more dangerous now practised by means of abdominal section, for the removal of the uterus and appendages, and especially in suppurative cases with multiple pus-centres. It was vaginal hysterectomy for malignant disease of the uterus which first paved the way to the more extended use of the vaginal route for such operations. He pays a fitting tribute to American surgery, when he said that this, like other of the great operations of recent times, emanated from a Southern surgeon. In New Orleans, in 1846, Dr. Dubourg fully described this operation, which he had repeatedly practised with success since 1829, but it was again forgotten until revived within the last decade, and vaginal hysterectomy for malignant disease of the uterus is now everywhere an accepted operation, which is rendered especially safe and rapid by the *forcé*-pressure method of Péan; and it was the French surgeon who extended the field to the removal of other contents of the pelvis by the vaginal route, resorting to the piece-meal removal, the *morcellement*, for the extirpation of masses too large to be delivered in their entirety through the vaginal opening. The leaders in this new departure are Péan and Sigond, of Paris, Doyen, of Reims, and Jacobs, of Brussels, and followed for the present by the French school only. In Germany and England these operations are practised but little, if at all, and in this country the vaginal route is limited to the removal of the uterus, vaginal hysterectomy for malignant disease, and perhaps for prolapse or inversion. Isolated cases of removal of prolapsed ovaries resting on the vagina, or small and conveniently situated ovarian cysts through the vaginal opening, are now and then performed everywhere, but this is a very different matter. The surgeons who are leading in this field vary somewhat in method, and in the extent to which they apply it, but the vaginal route now serves them, (1) for hysterectomies for the removal of malignantly diseased uteri, and moderately enlarged uteri, for hysterectomy by *morcellement*, for uterine tumors which do not extend above the navel. (2) For the bilateral removal of appendages with diseased uteri. (3) For the treatment of pelvic suppuration of all kinds.

(4) Dr. Jacobs even prefers the vaginal method for certain cases in which the appendages of one side only are to be removed. Péan limits hysterectomy by morcellement to benign growths, and to all cases of pelvic suppuration treated to day by a laparotomy; while Sigond still prefers laparotomy when operation is indicated in unilateral cases, above all in unilateral salpingo-ovaritis when non-suppurative. The indication given by Terrier and indorsed by Jacobs is, first, the resort to the vaginal route for cases in which suppurative pelvic peritonitis has returned, if laparotomy has already been practised; secondly, suppurative pelvic peritonitis, with fixation of the uterus and multiple pus sacs, while laparotomy may be resorted to in enucleable non-suppurative salpingo-ovaritis.

The advantages of the vaginal route are the rarity, if not absence, of shock in cases in which we would have to treat it if the abdominal method were resorted to; rapidity of operation, by reason of the forcé-pressure method, and the total absence of ligature or suture, nearness of the parts to the finger, and in aggravated pus cases guarding of the abdominal cavity from the pelvis proper or the field of operation by the adhesions and inflammatory products which form a perfect barrier. It seems the natural route for the reaching of parts below the pelvic brim. There is, after operation, perfect drainage established by the forceps and the dressing per vaginam, so that there is no possible stagnation. Recovery appears to be more rapid and more satisfactory than by the abdominal method, the forceps being removed in forty-eight hours, the patient sitting up on the fifth or sixth day, and moving about between the tenth and fourteenth, when cicatrization is completed.

Trephining as a Cure for Traumatic Epilepsy, by Dr. John T. Chapman, of Bessemer, Ala. He operated on a boy, who, some years previously had received an injury of the head by a blow fracturing the parietals. Three weeks after the injury he began to have epileptic convulsions. At the time Dr. Chapman saw the patient the convulsions had become more frequent, and with greater force. Two buttons of bone were removed at the seat of injury; there was considerable pressure from depressed bone; the membranes were hard and indurated. The indurations were cut out and edges of dura brought together by continuous suture. The wound healed by first intention. For two months after the operation the patient continued to have convulsive seizures, but they gradually grew less until they ceased. The operation was done four and a half years since. The patient is now eighteen years old, weighs 170 pounds, and works in a foundry. He believes the doctrine that depressed fractures of the skull without symptoms require no operative interference is in a measure responsible for many of the unfortunate sequelæ of head injuries.

Afternoon Session.

Dr. Kollock, First Vice-President, took the chair, and President Brown delivered his annual address. He selected for his subject

The Southern Surgical and Gynecological Association—Its Origin, Objects, and Aims.—He said six years ago a small band of earnest, brave, and determined Southern surgeons assembled in the city of Birmingham, Ala., with Dr. Haggard, as President, amid doubts, anxieties, and misgivings for the future, to found and organize this Association, and in this effort to build up an organization that would meet the advanced requirements of the times, and that should rank in point of talent, efficiency, and high-toned character with the other great institutions of the kind in this and other countries. But notwithstanding the stupendous difficulties encountered, the vast labor expended, and the many obstacles in our path, the Association stands to-day a monument of energy, enterprise, and indomitable will-power. Dr. Brown then traced the growth of the Association and referred to its work.

Some Remarks on the Surgical Treatment of Epilepsy.—Dr. B. E. Hadra, of Galveston, Tex., read a paper with this title. He thinks that modern researches promise to divest even the so-called genuine epilepsy of its mysterious functional character, and to make it consequently more accessible to surgical interference. Among the points he would mention as having to be cleared up is the deficiency in the knowledge of the great number of brain-centres that must exist. As an instance he mentions the unquestionable fact that very often the stomach or the intestines give the initial symptoms, but because we do not yet know these centres, and because the signals are very abstruse, it may easily happen that another group of muscles, which only secondarily become excited, is charged with giving the signal. The next point is to find the real seat of the primary morbid changes in the brain, which is not necessarily the focus belonging to the initial signal. Topographical and electrical localization map out only the latter. He insists that the induced current used in a different way will be all we may desire for such a purpose. It must be applied over a large area of the exposed cortex until a spot is met from where a certain group of muscles not only can be made to contract, but from where a regular epileptic fit can be elicited. This spot must be the locality of the morbid substratum, whether it coincides with the physiological focus of the muscles giving the signal or not; consequently this spot must be removed.

He concludes his paper with the proposition to have uniform blanks for operations on the brain, and to have the questions filled by a critical friend during the operation, in order to avoid neglect and to prevent post-operative imagination from playing its obliging part in the adjustment of the historical data.

The Management of the Epicystic Fistula. — Dr. John D. S. Davis, of Birmingham, Ala., read a paper on this subject. He said the epicystic surgical fistula is the title given to a suprapubic fistula into the bladder created by the surgeon for exploration, intra-vesical treatment, and drainage—a fistula which, acting as an artificial urethra, is capable of giving free access to the inside of the bladder for cystoscopic exploration, to provide a ready, convenient, and comfortable means of emptying the bladder at will, and give the surgeon a competent opening into the viscus for intra-vesical applications. It constitutes an essential element in the speedy and complete evacuation of the contents of the bladder in all epicystic operations, and imitates nature in the restoration of its own continuity as the pathological changes within the bladder subside.

Permanent after-drainage in all intra-vesical operations cannot be necessary, but is highly essential to secure good and sufficient drainage until the paravascular tissue is disengorged, the cystitis is relieved, and the urine becomes normal and passes per urethra unobstructed. And until this end is attained complete artificial arrangement for the escape of the contents of the viscus must be made. In such cases of prostatic hypertrophy, or malignant growths, when removal of the obstruction is impossible or contraindicated, the epicystic surgical fistula is clearly indicated and essentially necessary.

Dr. Hunter McGuire, of Richmond, reported a series of cases of "Tuberculosis of the Bladder."

Personal Experience in the Operative Treatment of Stone in the Bladder.—Dr. William T. Briggs, of Nashville, followed with a paper on this subject. He said living in the midst of the stone region, and in a city whose celebrity as a surgical centre has been long established, it has been his fortune to have met with an unusually large number of cases of vesical calculi. He had had two hundred and eighty-four cases of stone under observation during the past forty-two years. The Southern States had furnished the greater number of the cases; a few had come from Western States—Tennessee, Kentucky, and Alabama have supplied the largest number; but Georgia, Florida, Texas, Arkansas, North Carolina, Virginia, Missouri, and Illinois have contributed cases.

Two hundred and seventy-two of the number were males, twelve females. One hundred and fifty-three were children, or youths under twenty years of age; one hundred and thirty-one were adults varying in age from twenty-one to eighty.

In operations for stone he had not restricted himself to any single method. He had done all the operations, both cutting and crushing, and he considers it very fortunate that surgery has so many resources for the relief of this distressing and painful malady. The success of every method of operating largely depends on the preparatory treatment of the patient. The pre-eminent success of Dudley, Mott, and others was doubtless due to the judicious treatment employed in the preparation of subjects for the operation; and Dr. Briggs is sure that his own success has been greatly enhanced by a strict observance of the preparatory treatment.

In conclusion, Dr. Briggs said his experience in the surgical treatment of stone in the bladder would sustain the following propositions:

1. No method of operation is adapted to all cases.
2. Thorough preparatory treatment is essential to success.
3. Litholopaxy is *the* operation when the patient is an adult with a capacious and tolerant urethra with a bladder free from severe chronic cystitis and with a small or medium-sized stone or, if large, of soft consistence.
4. The suprapubic is the best operation for large and hard calculi.
5. The medio-bilateral should be chosen in all other conditions, because it is the easiest, safest, and best.

Hypertrophy of the Omentum in Hernia, with Specimen.—Dr. George A. Baxter, of Chattanooga, read a paper with this caption, and presented a specimen (congenital) from a negro, thirty-four years of age, which had existed until early manhood, about the size of a goose-egg. It was directly increased somewhat by working in a rolling-mill thirteen years ago, but has had a constant growth since that time, until it reached one-half or two-thirds the way to the knees, and became an unendurable nuisance. It was, therefore, removed, closure being made at the same time.

Treatment of Gunshot Wounds.—Dr. Willis F. Westmoreland, of Atlanta, read a paper with this title. The first of this class of injuries that he was called upon to treat was shortly after he had graduated, and it thoroughly convinced him of the fallacy of probing. He never uses a probe in a gunshot wound except as it may become necessary in the progress of a formal antiseptic operation. The probing rarely does any good beyond satisfying a morbid curiosity. Even if the wound is not infected by the probe itself, it allows the entrance of air. It destroys nature's occlusive blood clot, and in this way prevents prompt union.

(To be continued.)

Women Physicians in Turkey.—Judge Terrell, the United States Minister, has just gained a notable diplomatic victory. For several years the number of female physicians in Turkey has been increasing, notwithstanding the fact that Turkish law refused to recognize them as legitimate practitioners. Foremost among them have been the American missionaries, who have repeatedly won the highest praise for their self-denying work. They have, however, been greatly hampered by the fact that they could not secure regular Turkish diplomas, and the various foreign embassies have been very earnest in their efforts to gain for them official recognition. Hitherto they have failed entirely, but at last Turkish conservatism has yielded, and to the American Embassy belongs the honor of securing what neither Russian, French, British, nor German Ambassadors could gain.

Hydrocele.—Corrosive sublimate solutions (1 to 1,000) cause no pain whatever when injected, and invariably bring about permanent obliteration of the vaginal cavity. Where there is thickening, incision is better.—Troianofi.

PUERPERAL SEPTICÆMIA AND ANTISEPTICS—DISCUSSION AT THE OBSTETRICAL SOCIETY—EPILEPSY AND DEFECTIVE REFRACTION—SIR ANDREW CLARK'S FUNERAL—DISAPPEARANCE OF CHOLERA—ARREST OF HARNESS—THE "INDIAN OCULISTS."

London, November 11, 1893.

There has been a discussion on "Puerperal Fever" at the Obstetrical Society, *à propos* of a paper by Dr. Hicks, who held that it is not yet clear whether the variations in intensity are due to the amount of the poison received, or whether the poison is accompanied by other poisons, or whether a new phase of growth of bacteria may modify the intensity. But the most important part of the paper gave an account of two groups of cases of extreme virulence, evidently conveyed in every case by the attendant or the nurse. In some cases the attendant has suspended his midwifery practice without preventing recurrence on resuming it, though the later cases were milder. It was suggested that time diminished the dose of the poison; but other speakers pointed out that time only dilutes the poison, while antiseptics destroy it, and one said that a woman would be safer to be attended by a man who had just done an autopsy or attended an infectious case, but who used all antiseptic precautions, than by a man who neglected these and merely ceased practice for a time. Then followed some talk about defective sewerage and some comparison of the cases with diphtheria which perhaps illustrates rather the imperfect perspective of medical knowledge of some of our accoucheurs, for Dr. Thorne Thorne has conclusively established what Sir William Jenner long ago made probable, that the drains have nothing to do with the spread of diphtheria. It is strange that just as Sir W. Jenner's essay is republished the exploded hypothesis should find support in a learned society. Happily the President, Dr. Herman, was up to date, for he remarked that sanitary conditions had been shown to have little or no relationship to outbreaks of diphtheria, and he did not believe that sewer gas caused puerperal septicæmia. Dr. Cullingworth also regretted the importance attached to sewer gas, and mentioned a case in which the drains had been relaid at great expense, and he afterward found out that the attendant had gone to the patient direct from a scarlet-fever case without even washing his hands. I wonder how that attendant would be treated by a jury to which the danger of doing so had been explained if he were charged with causing the death of the woman. One speaker suggested that it is not necessary to change his clothes if the attendant washes his hands in carbolic water, 1 in 20; but he was followed by a prompt repudiation of such a risk, and the remark that if clothes could convey erysipelas or scarlet fever, it is at least likely that they could do the same with the poison of puerperal septicæmia. Dr. Lewers pointed out that hospital accoucheurs attended labors after being called to infectious cases: but thanks to their antiseptic precautions, without disaster, and this statement was supported by others, notably by Dr. Horrocks, who said he once did Cæsarean section forty-eight hours after performing an autopsy on a case of rapidly fatal puerperal disease. The most scrupulous antiseptic precautions were taken and no harm resulted.

Epilepsy is a subject of sad interest to every practitioner, so I may notice that it came up at the first meeting of the Ophthalmological Society, when Mr. W. Dodds gave statistics of 100 consecutive cases. Their refractions compared with normal eyes showed considerable differences, and 75 were ordered to wear glasses. Of these 23 were lost sight of. Of the other 52 there were 13 who had no fits for periods of four to twelve months; 36 were certainly improved and 3 unbenefited. All the cases had had medical treatment also, but Mr. Dodds concluded

that the correction of any errors of refraction will sometimes assist in the cure or relief of epilepsy. Of course it is impossible to separate the effects of the medicinal from the optical treatment in these cases, and one speaker was unkind enough to provoke a laugh by stating that a myopic patient of his who had never had fits developed them soon after the correction of his myopia by glasses.

The funeral of the late Sir Andrew Clark takes place to day. The first part consists of a memorial service at Westminster Abbey, after which the remains will be conveyed to Essendon, where the lamented physician had his country-house. The two Royal Colleges will be represented by their most distinguished office bearers—those of his own college in their official robes. Mr. Gladstone, Sir J. Paget, Sir H. Acland, Sir R. Quain, Sir E. Sieveking, Mr. Hulke, President R.C.S., Dr. Russell Reynolds, and Dr. Hughlings Jackson are the pall-bearers, and a great number of eminent men will attend.

No case of cholera has been reported in the United Kingdom for the last three weeks, and we are congratulating ourselves that the danger has passed, at any rate for this year. Those countries which had imposed quarantine on vessels from our ports have now removed the restriction.

Harness, of medical battery company notoriety, has been arrested on a charge of conspiracy to defraud, and is out on bail.

The "Indian oculists" who performed such atrociously cruel operations under promises to cure the blind have, after a lengthy trial, escaped on the plea of their ignorance; but the judge warned them that on any future occasion they would not be able to put in such an excuse, as the trial must have shown them. Perhaps, therefore, no such sickening and heartless proceedings will be again ventured upon.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 25, 1893.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	17	4
Scarlet fever	70	6
Cerebro-spinal meningitis	1	3
Measles	170	0
Diphtheria	150	53
Small-pox	11	2
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Anthrax Bacilli in the Mud of a Well.—Diatroptoff has succeeded in demonstrating anthrax bacilli in the mud taken from the bottom of a well near Odessa. An epizoötic of anthrax broke out on land where numerous flocks of sheep were pastured; several of the dead sheep were buried and the others removed to another pen several kilometres distant, and having a special watering pond. The infected pen was carefully disinfected, the walls being washed with sublimate, the earth raised to a depth of 25 centimetres, and replaced by fresh soil. On their return to the disinfected pen, the sheep, which had been perfectly well in the second pen, again began to be attacked by anthrax. A new change, with a second disinfection, was followed by a recurrence of the disease on their return to the former pen. The proprietor at last noticed that the epizoötic only recommenced when the water of this well was used—water avoided by the farm people on account of its brackish taste. When the well was filled up the epidemic ceased. The bacteriological examination of the water itself and inoculation of mice therewith gave negative results. The author sent for samples of the soil of the pen and of the mud at the bottom of the well from which the suspected water had been taken. No anthrax bacilli were found in the soil of the pen, but from the mud bacilli were obtained which killed rabbits and mice, their bodies presenting the *post-mortem* appearances of anthrax. Cultures made from their blood left no doubt as to the nature of these bacilli.—*British Medical Journal.*

Insurance of Opium Users.—Perhaps the most important evidence secured by the British Parliamentary Commission appointed for the purpose of investigating the opium question is that tendered by the management of the Oriental Life Assurance Company, which possesses what may almost be described as the monopoly of the native business in India. According to the testimony of the directors of that institution, no extra premium is charged to users of the drug, and this estimate of the risk seems to be confirmed by the surprising fact that during twenty years not a single claim has been paid for death which could have been attributed to the use of opium.—*The Tribune.*

A Bit of Official Wisdom.—The following paragraph is copied verbatim from a board of health report of a town not a dozen miles from Suffolk County. The lucid advice, as well as the English of this intelligent health official, are both worthy of notice: "Every person who is confined in a house owing to sickness and contagious diseases, should at all times be thoroughly covered with disinfectants, both externally and internally, to insure safety to themselves and to others, as in my mind a spread of the same is caused by carelessness on the part of people who know it all, and cannot be told by persons of experience."—*Boston Medical and Surgical Journal.*

Instances of Remarkable Fecundity.—When I was a resident medical officer in the Chester General Infirmary I knew an old lady in that city who was notorious as having been confined of twins fifteen times, besides some other single births. Her husband died lately, when his and his widow's lives were noticed in the local newspapers. I think that the old lady is still alive. She, poor soul, under some trying circumstances, lamented her lot—not that she had brought over thirty subjects to Her Majesty, but that thirty of them had not come in triplets, so that she might have been amenable to Royal bounty. Two other cases of interest in fecundity I met with during my tenure of office. I attended a baby, aged three months (who died) whose mother was then eleven years old. It was said that the girl-mother had been subjected to regular intercourse with a grown man since the age of eight years. As an instance of early conception the case was recorded in one of the medical journals. At Handbridge (just without the castle walls) I visited a fishwife who was nursing two babies—her own baby and her great-grandchild. The two intermediate generations I saw. The great-grandmother told me that she was sixteen when she was married, which, giving the same age to her daughter and granddaughter for the same events, would but make her forty-eight when I saw her.—J. Lloyd-Roberts in *The Lancet.*

Treatment of Typhoid Fever with the Blood of Immune Persons.—Dr. Hammerschlag records, in the *Deutsche Medicinische Wochenschrift*, No. 30, 1893, five cases in which the blood of patients who had recovered from typhoid fever was transfused to patients suffering from the same disease. Coagulation was hindered by adding four per cent. of oxalate of soda. Dr. Hammerschlag started on the principle that the blood of convalescents from typhoid fever contains a substance which antagonizes the typhoid poison. The results were not very definite. In one case a remarkable fall of tempera-

ture occurred in the night following the injection, but the following evening the fever returned. One case ended fatally. In three cases the blood was taken from patients only recently free from fever; in the other two cases the donors of the blood had been for from five to seven weeks free from fever.

Japanese Dentistry.—While Mr. Hubbard was minister to Japan, I visited that country and spent a pleasant week with him. One day I was troubled with toothache, and Mr. Hubbard took me to a dentist and explained to the saddle colored operator that I wanted the grinder extracted. I was placed in a bamboo chair and tilted slightly back. The dentist examined my teeth, talking volubly meanwhile to Uncle Sam's representative. Suddenly his thumb and forefinger closed on the troublesome tooth, and before I had the faintest idea of what was going to happen, he lifted it out and held it before me, smiling at the same time that vacant smile peculiar to the children of the Orient. "You were waiting for the forceps, were you not?" said Minister Hubbard with a laugh. "They don't use them here."—*Ohio Dental Journal.*

Medico-literary Activity in Russia.—During 1892 the number of medical journals appearing in Russia was 49; of these, 33 were published in St. Petersburg. Since the commencement of the present year the total number of journals has increased to 54; of these, 35 are published in St. Petersburg, 3 in Moscow, 7 in Warsaw (1 in Russian and 6 in Polish), 2 at Kharkoff, and 1 at Dorpat, Brjansk, Woronesh, Kasan, Kieff, Lipezk, and Tschernigoff respectively. In 1877 only 8 medical periodicals were published in St. Petersburg. A proportionate increase has taken place in the output of books and pamphlets; the number of these published in Russia in 1877 was 34; in 1892, 814. The literary activity of Russian medical men has developed in a striking manner in recent years; thus, while the number of books published in 1889 was 198, it has grown to 254 in 1890, to 324 in 1891, and to considerably more than double that number in 1892.

A Suggestion for the Treatment of Skin Diseases.—Dr. Alston, of Trinidad, is the inventor of an ingenious and possibly effectual plan of securing the entrance into the diseased integument of medicaments destined to combat the ravages of the parasite of tinea tonsurans. His idea, which he is unfortunately debarred from putting into practice owing to the scarcity of this particular parasitic disease in his parts, consists in the application over the affected area of a miniature air-pump *qua* cupping-glass, the which would, it is conceived, withdraw the air from the skin and render it more than usually porous. This having been done, and the cupping-glass being retained *in situ*, the medicament is sprayed therein, to be greedily absorbed by the thirsty integument.

Notes on New Remedies gives a list of one hundred and twenty-four new definite chemical products which have been introduced into more or less use in the last few years. Looking over the list we find we can easily scratch out all but twenty-six. The remainder are of no use or have equally good substitutes.

Cats and Diphtheria.—Dr. Edmund Gwynn, medical officer of health for Hampstead, has forwarded us the following case, which may be of interest at the present time, when diphtheria in London is on the increase, as showing once more that the disease may sometimes be traced to domestic pets: In February last a cat in a tenement-house situated in Fleet Road was noticed to be very ill and suffering from a bad swollen throat. On February 24th a child, aged five years, who had been nursing the cat, was sent into the Northwestern Hospital, suffering from diphtheria. The cat was subsequently sent away for treatment, but returned to the premises on July 22d, enticed back by the children of the house, with whom it was a great favorite; it was still in a bad state of health, and suffering from an unhealed abscess in the vicinity of the throat. On July 26th two other children were found to be affected with sore throat, and one was removed to the hospital suffering from diphtheria on July 31st. The father of the children, believing the cat to be the cause of the infection, destroyed and buried it —much to the indignation of the landlady—so that no opportunity was afforded of examining the animal.—*British Medical Journal.*

Army Medical School, Washington, D. C. (Session of 1893–94).—*Order of Duties.*—Daily, except Saturdays, Sundays, and holidays: 9 A.M. to 12 M.—Instruction in Pathological Laboratory; 1 P.M. to 2.50 P.M. —Instruction in Chemical Laboratory; 3 P.M. to 4 P.M. —Lecture. Saturdays: 9.30 A.M. to 10.30 A.M., at Hospital Corps School of Instruction, Washington Barracks —Practical Instruction in Litter and Ambulance Drill and First Aid; 1.30 P.M. to 3 P.M., in Riding Hall, Fort Myer, Va.—Practical Instruction in Equitation. The lectures will be delivered as follows: "Duties of Medical Officers"—Wednesdays, except November 22, 1893, and January 24, 1894; "Military Surgery," etc.—Thursdays throughout the course; "Military Hygiene"—Fridays, except February 23, 1894; "Military Medicine"—Tuesdays, November 7th and 14th, Wednesday, November 22, 1893, and January 24, and Mondays, January 29, February 5, 12, and 19, 1894.

Auxiliary Courses.—Bacteriology, General Sternberg —Mondays to and including January 22, 1894; Military Law, Major G. B. Davis, Judge Advocate, U.S.A.— Tuesdays in January, 1894; Comparative Anatomy, etc., Captain J. C. Merrill, Med. Dept. U.S.A.—Tuesdays in December, 1893; Medical Jurisprudence, Dr. Robert Fletcher, F.R.C.S., Eng.—Tuesdays in February, 1894 (except the 27th); also Friday, February 23d; Parasites in Man, Professor C. W. Stiles, M.D., Department of Agriculture—Tuesdays, November 21 and 28, 1893. Due notice of any change of programme will be posted on the bulletin board —Walter Reed, Capt. and Asst. Surg., U.S.A., Secretary of the Faculty.

Neurectomy in Spasmodic Torticollis.—Gardner and Giles, in a paper on neurectomy in spasmodic torticollis and retrocollic spasm, report two cases, one of spasmodic torticollis, the other of retrocollic spasm without torticollis, which were treated by exposure and partial resection of both spinal accessory nerves and subsequent division of the posterior branches of the second and third cervical nerves. This treatment was completely successful in the first case, nearly five years having elapsed since the last operation; in the second case it was followed by cessation of all bad symptoms, save some trifling spasmodic movements of the deep rotators of the left side, which it is anticipated will be completely cured by another operation. Gardner, who had charge of these cases, claims precedence over Keen with regard to section of portions of the posterior branches of the second and third cervical nerves, having performed this operation a few months before it had independently been thought out and practised by the latter surgeon.

Surgical Significance of Dust.—The interesting editorial of Warbosse (*Boston Medical and Surgical Journal*) in which he describes at length the important work of Hægler, deserves a careful perusal. The article is too long to report in detail. The results reported have an important relation to operative work and wound treatment. The work seems to show that the important factor in atmospheric infection is dust; that this contains the germs; that air in a room unagitated contains few germs; that the atmosphere of an unclean room in a state of rest is freer from germs than that of a comparatively clean room in a state of commotion. Dry dressing and dry treatment of wounds allow a greater distribution of germs into the atmosphere than moist ones. It is true that the danger of infection from air containing pathogenic microbes is much less than from other sources.

Still, it is of enough importance to be considered when one is striving for complete asepsis. Hence attention should be paid to diminishing or eliminating the harmful effects of dust. Also to prevent the conversion of infectious material into dust, as by the dessication of pus, agitation of dry discarded dressings, or in similar ways. The methods proposed for the removal as far as possible of this liability of infection during operative work or the dressing of wounds were to avoid agitation of the air at such times or to precipitate all dust by charging the atmosphere with moisture, so that during its precipitation the dust is carried down with it and the air is thus cleared as during a shower. The moist surface thus produced holds such precipitated dust fast for a time, and prevents its renewed circulation by air-currents.

The Physician the Best Confessor.—In her little work entitled "Pensées," the Queen of Roumania writes: "It is better to have a physician for a confessor than a priest. You tell the priest that you detest mankind. He answers, 'You are not a Christian.' The physician gives you a dose of rhubarb and you love your fellow-being. You tell the priest that you are tired of living. He answers, 'Suicide is a crime' The physician gives you a stimulant and you immediately find life supportable."

Should Impotence be Treated?—The answer to this question, as given below by Dr. W. F. Waugh (*Times and Register*), will strike every reader as wise, honest, and perhaps timely. Dr. Waugh says: "I mention this case to emphasize the point I have called attention to more than once, that impotence is unusually conservative; and that it is only in exceptional cases that it should be treated by a conscientious physician. If we ask ourselves the question in every case of impotence: 'Should it be cured?' in the vast majority of cases the answer must be another negative. I am well aware that this means the loss of our patient's custom in many cases, but the true physician can better afford to lose a patient than to lose his own self-respect, by pandering to lustful appetites when we know they will be indulged to the detriment of the individual. This must be plainly stated to the patient; no half-way measures are possible. To give placebos is to surely lose the confidence of your patient; who may respect a manly refusal, but never a shuffling, half-hearted, or pretended acquiescence in his wishes."

Hypnotism in Court.—The judicial authorities in Holland decided recently to have a suspected murderer hypnotized in order to extract evidence from him as to where the bodies of his alleged victims might be found. The law in that country allows this to be done to persons on trial in order to extract evidence from them which they will not give when awake. It says that any knowledge of the crime which may be thus derived shall not be used to the prejudice of the accused, but it is scarcely probable that advantage should not be taken by the prosecuting lawyers of the facts so brought to light.

Chronic Alcoholism may be attended with symptoms resembling those of general paralysis, but those due to the action of alcohol are not progressive if the alcohol be withheld, while those of general paralysis continue to a fatal issue. The lesions of chronic alcoholism also most closely resemble those of general paralysis, but careful examination shows that the morbid changes fundamentally involve the intima of the vessels, while in general paralysis it is especially the adventitia that suffers.—*Medical and Surgical Reporter.*

Calomel in Diphtheria.—Dr. W. F. Hani, of Elkhart, Ind., writes to say that Dr. W. H. Daly, of Pittsburg, does not advocate anything new when he advises calomel in diphtheria. Dr. Hani says that he has used it with success for many years, as have many of his medical acquaintances.

Mortality of Russia.—The annual report upon the health of the Russian empire during the year 1890 has just been published by the Medical Department of the ministry of the interior. The total population in 1890 was reckoned at 116,652,610; the birth rate was 46.1, and the deaths 33.5 per 1,000. The natural increase in the population was 12.6 per 1,000. These figures show a marked falling off in the natural growth of the population. In 1887 it was 15 per 1,000, in 1888 it was 16 6, and in 1889 it was 14.3 per 1,000. The figures are approximate only. No general census has been taken since 1857, and the population in subsequent years has been obtained by a calculation based mainly upon the "natural increase" or preponderance of births over deaths. In some parts of Russia (for example, the territories in Central Asia, acquired since 1857) the inhabitants have never been counted, and their numbers have only been estimated by indirect means. A fresh census is, it is stated, to be taken this year. The death-rate in European Russia in 1890 was 34.2 per 1,000. The corresponding figures in the years 1887, 1888, and 1889 were respectively 31.8, 31.4, and 33 4 per 1,000. The increase in death-rate in 1890 is attributed to the greater prevalence of typhoid fever, whooping-cough, measles, phthisis, dysentery, cholera nostras, gastro-intestinal catarrh, and some other diseases, and to the epidemic of influenza.

Diagnostic Threatenings.—In matters medical, as most things else, our fears are frequently but chimeras; and in no branch of the science, as both profession and people can attest, is this better illustrated than in diagnostics. Nothing, perhaps, is more common with some physicians than to threaten their patients with evils that never materialize—a practice that works incalculable harm to all concerned. Smith is "threatened with pneumonia;" Jones' wife, "with typhoid fever;" Brown's baby, "with measles," "meningitis," or "mumps;" and so on till both patient and family are on the tenters, the whole neighborhood agog, and the doctor's end apparently attained. At times, indeed, these threatenings are the convictions of an honest, though indiscreet, attendant; but oftener, no doubt, they indicate the craftiness of one who would either conceal ignorance or further selfish interests. There is hope for the former, for he may yet learn the language of disease, and appreciate the value of reticence. His threats simply mean that he thinks a certain disease exists, but, as the symptoms are not plain to him, is not quite sure of the diagnosis. Most, if not all, intelligent practitioners know, of course, that one can be threatened with, and still escape, the exanthemata, pneumonia, enteric fever, and other specific diseases, although we have in mind one who has threatened his patients so much that he is at last fearful himself; and thoughtless statements to the contrary are to be counted a mere *lapsus linguæ*. The position of the latter—the pseudo-diplomat—is, however, in his opinion, impregnable. If the prophecy be fulfilled, he was the prophet; if not, he prevented it; and, whatever happens, he poses as a mighty man, receives the plaudits of the crowd, and gathers much gear. His success is but ephemeral, however, for, like everything unreal, his methods cannot stand the test of time. He is watched; confidences are exchanged; a better man is consulted; comparisons unfavorable to the suspected are made; and thus is he shorn of his glory. He may, as in a case known to us, fall a prey to the malingerer, and then his defeat is a veritable rout. An adept at "breaking up" all manner of diseases may flourish for a season, but he will oftener succeed in breaking down the confidence of the public. If he would succeed, the physician must observe much, think more, and reserve most; and the better balanced the man of medicine, the more will perception, reflection, and discretion be found to enter into his composition.—*Massachusetts Medical Journal.*

Weber's Canalicular Knife.—Dr. W. L. Bullard, of Columbus, Ga., writes to say to the many readers of the MEDICAL RECORD, and particularly to those who do eye surgery, that they will find Weber's canalicular knife a most serviceable auxiliary in performing tenotomies for the correction of the various forms of heterophoria.

THE DIETETIC AND HYGIENIC MANAGEMENT OF CERTAIN TYPES OF OCULAR DISEASES.[1]

BY EDWARD S. PECK, A.M., M.D.,

VISITING SURGEON TO THE OPHTHALMIC DIVISION, CITY HOSPITAL; OPHTHALMOLOGIST TO ST. ELIZABETH'S HOSPITAL; CONSULTING OPHTHALMOLOGIST TO THE MONTEFIORE HOME, ETC.

THE literature of the dietetics of ophthalmic practice is exceedingly meagre. One reads of the treatment of ophthalmic diseases to find only a bare reference to diet as playing any part in their management. English text-books on ophthalmology lay more stress on this factor of treatment than those of any other nation. The reason of this is either that cachexia plays so large a *rôle* in all diseases in England, or that good food, and a liberal supply of it, are regarded as essential factors in the treatment of disease. Whatever be the reason, it is certainly the fact that English ophthalmological literature, and especially that of the text-books, argues for discrimination and liberalism in diet. If one goes carefully through the complete German text-book of seven volumes, edited by Graefe-Saemisch, the items referring to the dietetic management of chronic and systematic diseases of the eye are either neutral in character, or so general as to fail of proper discrimination; and they are usually relegated to the end of the chapter, as if of little or no importance.

The purpose of this paper is to emphasize the necessity of a proper dietary in the management of certain forms of ophthalmic disease; not to individualize it over and above well-established means, the judiciousness of whose selection cannot be questioned.

A proper dietary is to be regarded as complementary, and not antithetic, to local treatment. A discussion of local therapeutics is purposely avoided, as not coming within the proper scope of this paper. On the other hand, its scope is not a consideration of the diet in acute and inflammatory attacks of various ocular tissues, as, for instance, a low diet in acute iritis, or a depleting diet in glaucomatous inflammation, or other forms of acute inflammation of the optic nerve; or, still more, the abstemious diet of cyclitis, panophthalmitis, etc.; but its chief purpose is to emphasize the necessity of alimentary and hygienic nutrition in *chronic* forms of disease of the cornea, iris, lens, vitreous, optic nerve, and retina, and in fugitive pains and neuralgias connected with the ocular region. The practitioner of ophthalmology knows that for certain diseases of the eye there are remedies whose action is almost specific, and whose success is always assured; but, at the same time, he knows well that routine treatment will not suffice to prevent a return of the same evil, nor ward off an idiosyncrasy due to vicious habit.

Before proceeding directly to a classification of the clinical types of ocular disease to be reviewed by this paper, with a view to the argument for special dietary, it is essential to have a clear understanding of the properties of elements of diet, with reference to their metabolism, and to their capacity as tissue-builders, and in this connection let us also remember that badly selected foods are the cause and promoters of diseases to an amount far beyond the usual calculation. What, then, are the *elementary principles* of the *perfect* and *complete* food of which the type is milk? In studying these principles we are obliged to enter somewhat the domain of physiological chemistry.[1] These elements are best represented by four classes:

I. The albuminates or proteins, or proteids, as they were formerly called. Examples of this class are albumin, fibrin, myosin, globulin, and casein, from the animal kingdom; gluten and legumin, from the vegetable kingdom.

II. The fats, or hydro-carbons, embracing the various animal and vegetable fats, oils, wax, etc.; the best example of this class is butter.

III. The starchy and saccharine elements used in food, called carbo hydrates; examples of this class are starch, and the sugars of cane, grape, and milk.

IV. Water, holding the minerals in solution, such as sodium and potassium chlorides, calcium and magnesium phosphates, iron, etc. While these classes play a separate chemical and physiological *rôle* in the system, there is no doubt that in tissue repair, calorification, and storage the members of one group may replace those of another; also, that perfect health cannot exist without the combination of all four classes.

The principal functions of food in the system, and the nutritive constituents are, in brief:

a. To *form* the tissues and fluids of the body.
b. To repair the *waste* of tissues.
c. To be *stored* for future consumption.
d. To be *consumed* as fuel.
e. In being consumed to protect tissues or other food from consumption.

The proteins, or albuminates, contribute to form tissue, as muscle, tendon, and fat, thus playing a large part in the chemistry of nutrition. They also serve as fuel for the production of heat.

The fats, or hydro carbons, form fatty tissue, not muscle, and they do this by being split up into simpler products by the agency of the cellular tissues; they also serve as fuel, and their potential energy or calorie-standard is great; but it must not be supposed that fat is the same easily combustible substance in the organism which it is without. The fats are sparers of albumin. It is well known that animals fed on lean meat lose in the albuminous constituents of the body; while under a diet of less meat, with a little fat, the equilibrium of metabolism, or the nutritive balance, is quickly established. The staying power of fat in muscular over-exertion was strongly maintained by Ebstein; and it is quoted in support of this theory that in the Franco-Prussian war of 1870 the German Emperor issued a daily ration of 250 grammes of fat bacon.

The carbo-hydrates, or starches and saccharines, appear to have much in common with the fats; but unlike the fats and albuminates, they do not enter as such into the structure of the tissues. They are converted into glucose, or grape sugar, and they immediately develop into heat and mechanical work. Pavy believes the so-called "amyloid substance" of the liver, or glycogen, is the result of the first conversion of the carbo hydrates, and that it is from this that fat is metabolized. In brief, the function of the carbo hydrates, or starches, in the organism, is to contribute to the production of heat, and to increase certain constituents of the body, especially albumin and fat.

The fourth class of foods, water and minerals, is in every

[1] Read before the Northwestern Medical and Surgical Society of New York, June 14, 1893.

[1] Yeo: Food in Health and Disease.

tissue of the body. Sodium chloride plays so important a *rôle* in the solids and fluids of the organism that its entire withdrawal from food would be fatal. Calcium phosphate is in even larger proportion in every tissue, while it forms more than half the bones. Of the other salts — sodium carbonate and bicarbonate, sodium and potassium sulphates, potassium chloride and magnesium phosphate—it is not pertinent to speak here. The two basic salts, potash and soda, have a different distribution in the organism, and cannot replace one another. The potash salts are found especially in the tissues, as the blood corpuscles and muscular fibre; and the soda salts in the interstitial fluids. Only one of these salts, sodium chloride, is introduced into the body added to dietary articles, while all the others are taken in as constituent articles of food.

Man, being an omnivorous animal, obtains his food from every source, and seeks other ingredients and compounds not in the four described classes, such as stimulants and condiments. While it cannot be properly said that these latter have a direct nutritive function, they do unquestionably play a useful *rôle* by stimulating the appetite, promoting and assisting digestion, and by acting on the peripheral nerves of taste and smell. For instance, alcohol does not form tissues, but it does serve as fuel. Tea, coffee, and meat extracts do not form tissues, nor do they serve as fuel, but have a various and definite action on the brain and nervous system.

It will not be out of place to devote some time to the consideration of various staples of food from both the animal and vegetable kingdom, as it is only by a proper appreciation of their chemical constituents as tissue-builders, as calorifiers, or as storage, that we can adapt them physiologically to the needs of ocular diseases amenable to, and dependent upon, a dietetic treatment. In the first place, the flesh of animals, or animal food, has this advantage, viz., that it furnishes the same chemical constituents as the bodies it is destined to feed. It is rich in albumin and nitrogen, and contains fat; it is usually more easily digested and metabolized than vegetables; it is easily cooked; it stimulates the senses of taste and smell, and contains the necessary alkaline salts and iron. On the other hand, foods obtained from the vegetable kingdom contain less albumin and fats than those taken from the animal world; they are not as rich in nitrogenous elements, and exist chiefly as carbo-hydrates, and, as a rule, contain little fat. The differences in these particulars are shown in Hoffman's well-known table of the percentum of nitrogenous constituents—fat, carbo-hydrates, and salts—in fat and lean beef, peas, wheat, and rice; but this table need not be reproduced here. It is an undebatable fact that vegetable foods are less digestible and less assimilable than animal foods.

It is unnecessary to touch upon the whole body of foods from either kingdom—of certain articles we may venture a passing notice. Fish, for example, affords an important part of animal food. In some varieties of white fish the albuminates, fat, and gelatine consist of nearly fifty per cent. of the animal; of their great nutritive value there can be no doubt; and with some nations fish constitutes almost the sole article of animal food. That it has acquired the reputation of being a so-called "intellectual" or "brain food" is due to the fact of its easy digestion by persons of quiet and studious occupations. Agassiz writes of fish as "refreshing to the organism, especially after intellectual labor," and adds, with an attempt at pleasantry, that "its use cannot turn an idiot into a wise nor witty man," but that it is "favorable to brain development."

Milk is the *complete* or *perfect* food, if there be one, and next to milk, eggs. The purposes of this paper will not permit a full reference to the advantages of a milk dietary in certain diseases of the eye, as its chemical and physiological characteristics are so well known to our profession. It contains the four classes of elementary constituents necessary to the complete alimentation of young life, and may be used for an indefinite period as the chief food for adults in different phases of disease. The casein, butter, lactose, and alkaline salts, form over thirteen per cent. of the milk itself, and all of them play an important part in the metabolism of digestion. Cream, kumyss, kefyr, buttermilk, and butter are useful articles of diet, and are of especial use as aids to nutrition in some of the lower types of non-inflammatory diseases of the cornea and sclera.

Eggs, like milk, furnish all the elements of nutrition in a concentrated form, and constitute another so called "complete" food. The white contains chiefly albumin, while the yolk exceeds in fat and solids. Eggs are easily digested if raw or lightly cooked, but when hard are very indigestible. The yolk of eggs should not be given as food to the patient suffering from gouty diseases of the eye, such as episcleritis, neuralgias due to corneal disease, certain forms of chronic irido-choroiditis, and choroiditis, or where these and kindred gouty diseases of the eye are associated with uric-acid deposits in urine of a high specific gravity as 1.030 +.

While eggs are a highly nutritious diet I do not believe they should be made a staple of diet in patients suffering from ocular diseases consequent upon albuminuria, such as retinitis, muscular asthenopia, muscular insufficiencies, styes, frontal headache, vitreous opacity, diffuse spots on the lens, etc. There are some persons who cannot digest eggs without developing toxic symptoms. Setting aside these cases of idiosyncrasy it is interesting to note the different results which have followed the ingestion of large quantities of raw, or uncooked, whites of eggs. Stockvis and Nussbaum found egg albumin unaltered in the urine after this experiment. Lauder Brunton failed to produce albuminuria after swallowing six raw eggs; Maguire's experiment with twelve raw eggs, and that of another observer, quoted by Grainger Stewart, with nineteen raw eggs in thirty-six hours, failed, both of them, to induce albuminuria.

Under the head of wines there are a few observations to be made of the highest importance. Important as they are—and I think that does not admit of discussion—I shall dispose of wines in a few words. From a dietetic point of view wines consist of alcohol, sugar, tannin, free acid, and ether. Dujardin-Beaumetz conveniently divides wines into four groups. I. Spirituous wines. II. Red or astringent wines. III. White or acid wines. IV. Sparkling wines. The spirituous, or *liqueur* wines, contain from fifteen to twenty-five per cent. of alcohol; they are too "heady" and too slow of elimination to be placed in a dietary for chronic invalids, with rare exceptions. The astringent wines contain tannin, and some of them, as the clarets of Bordeaux and Hungary, are very useful as tonics and tissue-builders in chronic diseases of the ocular apparatus associated with malnutrition. These wines contain from seven to twelve per cent. of alcohol. The best sparkling wines are the champagnes: when pure, these wines contain from twelve to fifteen per cent. of alcohol, act rapidly as a restorative and stimulant, and by their carbonic acid allay irritability of the stomach. Sir William Roberts has made some useful observations in regard to the action of wines on the digestive processes, and among them the following may be noted as of practical worth in the dietary of chronic diseases: Sherry, hock, claret, and port wines retard digestion to a large degree. This is due to the *acid*, and not the alcohol, contained in them. If they be mixed with an alkaline water, this disturbing effect is entirely removed. In his article on "Dietetics and Dyspepsia" he says that "alkaline table waters greatly mitigate, or wholly obviate, the retarding influence of these wines on the digestion of starch." He found that sherry retarded the time of complete digestion; and that sparkling wines impeded digestion less than still wines. To quote the same author in another article,[1] "those wines agree best and are most useful which are absorbed and eliminated from the system with the greatest rapidity." In any

[1] Food Accessories; their Influence on Digestion, Nineteenth Century, February, 1886.

case, where a light wine is prescribed in the dietary, it is always best combined with an alkaline table-water, as Vals, Kissingen, Lithia, etc.

The object of food is to build up tissue and to repair waste; to preserve a nutritive balance between bodily income and expenditure; to increase healthy activity and to prevent loss of weight. In this connection it would be of great interest to follow out different standards of dietaries in daily use in different classes of persons, and the different characteristics of individuals as to diet. These questions have to do with the diet of the soldier at home and in the field, the student at college, the artisan, the hospital and asylum patient, etc. But that is not to our purpose. It is for us to remember that in no branch of medical practice is judicious discrimination as necessary as here. As in other departments of practice, the selection of a dietary goes by fashion and in cycles. At one time limitation of diet was in vogue; while now, excess in diet is the thing, and both have received the convincing argument of scientific reasoning.

Of the Americans it may truthfully be said, they overeat; that the well-to-do and moderately circumstanced people indulge in an excess of meats and sweetmeats; while the very poor practise the worst economy in the purchase and use of their food.

It is of interest to study the tables of different observers with reference to the daily consumption and cost of foods of different nationalities and of different classes of workers of the same nation. The tables of Professor Voit, of Munich; Sir Lyon Playfair, of England, and Professor Atwater,[1] of Massachusetts, show a widely differing amount of food purchased and used by parallel groups of workers. I will instance only a few, taken from calculations of classes of workers in the United States, where wage-workers and people generally are better fed, do more work, and receive more pay, than in any other country. Classes, such as college students' clubs in New England, college football teams, machinists, brickmakers, and teamsters have a daily range of food consumption of from 661 to 1,695 grammes, or 1½ to 3¾ pounds avoirdupois. Roughly speaking, the protein and energy of the various American dietaries exceed those of the European dietaries by about fifty per cent.

Some interesting data might be introduced here, because they have a bearing on the practical utility of a strict dietary in large bodies of persons in health. The German army, when on a peace footing, had distributed to it, as the daily ration of the soldier, 633 grammes of food; on a war-footing, the daily ration was 681 grammes, an increase of 50 grammes, or about seven per cent. Bearing on this fact, it is well known that King William of Prussia, afterward Emperor of Germany, when his armies reached the French border, issued a daily ration of 773 grammes, which was regarded as extraordinary. The victories of Strasburg and Sedan soon followed. Frederick the Great's maxim was—"If you wish to build up the army you must begin with the stomach." Von Moltke, the great German strategist and commander, argued before the German Parliament that the greatest expense in the army budget lay in insufficient nourishment. The extraordinary ration of 773 grammes, just alluded to, provided 157 grammes of protein and 4,650 units of potential energy daily. The figures given for college teachers, lawyers, and physicians mean larger dietaries to intellectual labor than to ordinary labor, in Germany, England, and the United States. Strange as it may appear, the relation between food and intellectual labor has never been accurately studied experimentally, and the theory that large quantities of protein, fat, and carbohydrates are essential to successful mental effort has never been substantiated by figures. Has it ever been proved, ask the physiologists, that people of studious and sedentary habits demand large quantities of food, as we know is the physiological fact with those engaged in vigorous muscular exercise, on account of their muscle-waste and muscle repair?

[1] Professor W. O. Atwater: Food and Health, Transactions of the American Public Health Association, 1889.

Some of the tables indicate intemperance of eating on the part of the intellectual world, and, as to the use of beverages, the written and unwritten law of American life, defined both by social custom and by legislative edict, imply manifest intemperance.

I hope, Mr. President, that I will be pardoned for this digression into the field of dietaries of people in different classes of life. My apology is that they are not only interesting as studies, but they also serve to establish the purpose of the earlier part of this paper, that a knowledge of the essential elements and constituents of food is necessary to their judicious selection.

So far as the dietetic treatment of certain types of ocular disease is concerned, I shall, as previously stated, call attention to the advantages of a judicious dietary in chronic diseases of the cornea, sclera, iris, lens, vitreous body, optic nerve, and retina, and to certain affections of the lids, ocular muscles, and neuralgias. No attempt will be made to individualize these different anatomical theories by their histological elements, but to differentiate vicious habits, due to syphilis, gout, rheumatism, scrofula, tuberculosis, and malnutrition.

Syphilis may attack almost every tissue of the eyeball and its appendages. Its advances upon the cornea and sclera are so insidious as sometimes to escape observation, and it is frequently only after its invasion of iris and choroid that its true character becomes known. The interstitial deposits of fatty foci in the cornea, the gradual loss of the gelatine and chondrin of the sclera, and the bluish, or blue and white spots on the latter tunic, due to its thinning, and to the consequent demonstration of the hexagonal pigment of the choroid, are the common expressions of pronounced inherited syphilis. The iris in constitutional syphilis has a worn out, *blasé* look; a bright blue iris acquires a slate gray color; a brown hazel iris becomes a dirty green, and is sometimes intermixed with a dirty yellow. The anterior surface frequently has a swollen and nodular appearance, while the pupillary rim is irregular and festooned like an old-fashioned purse-string. The latter appearance is often present when plastic deposits have not attached the iris to the lens. In addition, the first evidence, so far as the iris is concerned, of an old syphilitic iritis, may be the presence of isolated spots of pigment on the anterior capsule of the lens. This revelation, by dint of the ophthalmoscope, has occurred over and over again to the observer, and has given the first evidence of unsuspected syphilis long since exhausted. The choroid and iris are the chief habitats of syphilis in the eye. If the choroid be attacked alone, it does not fall to the notice of any observer until the atrophic stage of disseminate choroiditis, with loss of vision in intermitting spots, has occurred. Pain is not a concomitant symptom, and vision gradually deteriorates until it is averted by specific treatment and diet. Such loss of vision implies central or equatorial choroiditis, and when it fully invades the macula lutea the eye becomes totally blind. Peripheral choroiditis always implies a limited invasion with only slight alterations in central vision. Patients with syphilitic choroiditis in the active stage rarely come under the physician's notice. It is only when material loss of vision has transpired, namely, after months or years of progressive choroidal degeneration, that advice is usually sought. Syphilis of the retina, while less common than choroiditis, occurs quite rarely as an isolated disease. Vision is much impaired, due to a stasis in the retinal veins, and a serous infiltration of the subretinal connective tissue. Idiopathic syphilitic inflammation of the optic nerve is very uncommon. Indeed, it is doubtful if syphilis of this nerve ever exists, except as consecutive to a gumma in the optic tract, and then it occurs as a descending neuritis, and is usually bilateral.

Syphilitic atrophy of the optic nerve exists as a factor of locomotor ataxy; according to Erb's statistics, it is probable that a very large per cent. of cases of locomotor ataxy have their origin in an old syphilis. Loss of the reflex of the iris and unequal size of the pupils, with optic nerve atrophy, point to syphilis as the cause of the ataxy. Some

nice, exhibitions of these ocular symptoms are at present in the Montefiore Home. Sometimes such patients present no spinal symptoms, and the knee-jerk is normal. Such cases must be carefully differentiated from cases of alcoholic multiple neuritis. I operated last winter with good results for cataract-extraction on a man with such suspicious syphilitic involvement; obviously optic-nerve atrophy was not present. Competent advice proved to me a case of multiple neuritis due to alcohol. Patient was for several weeks on a special diet, largely of milk and eggs, and made a good recovery with very useful vision.

In my service at the City Hospital last year there were two patients with gumma of the motor tract (one of which was presented to this Society with ophthalmoplegia), both of whom had neuro-retinitis syphilitica, and both of whom materially improved under specifics and a milk-and-egg diet. I have had for two years under observation a young girl from Brooklyn with double choroiditis disseminata, chiefly in the right eye. Until the summer of 1891 she never had any useful sight, that is to say, did not read or sew, though she occasionally played on the piano. Right vision was $\frac{6}{100}$, left vision was $\frac{20}{50}$. No definite cause for the choroiditis is obtainable, but the constitutional factor is presumably syphilis. Small doses of iodide of potash, phosphoric acid, and quinia, with a milk, egg, and rare-meat diet; claret, with lithia water; Turkish baths with especial emphasis on the massage movements of the upper and lower extremities; cold baths at 65° F., with friction three times a week, have accomplished what may properly be regarded, in view of the obstinacy and rebelliousness of such cases, a satisfactory result. The right vision, previously $\frac{6}{100}$, is now $\frac{40}{100}$; left vision, previously $\frac{20}{50}$, is now $\frac{20}{20}+$. The bodily functions are well carried on, though the appetite is poor, even under a subsidence of the potassium iodide; the cheeks are red, fat has accumulated, and a thoroughly new life has been acquired in a previously cachectic young girl. I mention this case somewhat in detail, as it illustrates the importance of tissue-change and tissue-repair by means of dietary, hygiene, and systematic bathing. Syphilitic patients bear a milk diet well, and as with syphilis a parenchymatous nephritis with albuminuria is often associated, this diet is highly beneficial. I have such patients take one pint to one quart a day at intervals, never before breakfast, but, if possible, the last thing at night, with or without a piece of thin buttered bread. I sometimes insist upon a large glass of warm milk in winter, or cool in summer, at 11 o'clock in the morning, the patient taking a walk purposely some little distance to a milk-store or restaurant. It is the exception in my experience that they cannot take milk, cold or warm, in the full strength, or diluted with vichy, or seltzer, or lithia, or soda, if they really wish to receive benefit. When the alarming possibilities to vision are put before them, in cases of doubt or nausea, it usually suffices to bring such patients to proper and prolonged acquaintance with milk.

In iritis, next to atropine and hot fomentations, properly applied, nothing is so beneficial as the Turkish bath.

Gout and rheumatism enter largely into the etiology of chronic diseases of the cornea, sclera, iris, retina, and muscles. The cornea and sclera are tissues of a comparatively low grade of histological selection; that is to say, they have a large amount of fibro-elastic tissue as their scaffolding, while neither is a reservoir of blood in any sense. Rheumatic affections, when not located deep in the orbit, show themselves in the reflex pain of the cornea, due to the anastomosis of nerves from the fifth pair, with which it is richly endowed. Rheumatism, as a factor of iritis, has long been recognized, especially in the English text-books, while gout unquestionably predisposes to iritis. I have, on more than one occasion, observed gouty nodes on the iris in persons of a highly uric-acid diathesis. Manifestations of gout in the retina are in the form of hemorrhages; and these hemorrhages may be small or flame-shaped,[1] and occasionally globular. Galezowski, of Paris, has observed hemorrhages in the retina, which, on being absorbed, left white patches of sclerosed tissue, which were probably due to an atrophic spot in the retina and choroid lying over the white sclera.

I have observed several instances of linear and globular hemorrhages of the retina, evidently of spontaneous origin, which may have been due to gout. The hemorrhages due to Bright's disease of the kidney, to violent childbirth, and to trauma, are, of course, excluded here.

The ocular muscles and muscles of accommodation sometimes suffer paresis and partial paralysis, due to gout; spasm and paresis of accommodation are not uncommon after severe attacks of acute rheumatism. In this group of ocular diseases we are naturally prone to treat the special complication, so far as the eye goes, and to forget the serious constitutional factor, until the general system has very much deteriorated. There is probably a larger element of gout in the wandering ocular pains, called reflex neuralgias, and causing temporary impairment of vision, than we at present are aware of. For these cases I most strongly advocate small doses of the potash and soda salts, free use of hot water as a beverage, beginning early in the day, thereby to wash out an acid stomach; a selected vegetable diet, in which the alkaline salts are in large proportion—the vegetables to be green, and the fruit fresh; a limited amount of meat, in which some fat shall be present; milk with alkaline table-water, as vichy, vals, seltzer, or lithia; a light, still wine, if wine cannot be avoided, always in moderate quantity, and with an alkaline table-water. It may be said of wine, as of starches and saccharines, the rule should be to avoid them absolutely. Every effort should be made to reduce the element of uricæmia to a minimum. Massage, cold ablutions with friction, and the Turkish bath are highly useful. Let us remember that thirty per cent. of gouty patients, according to Germain Sée,[1] occur in persons under twenty years of age. This may furnish a clew to the possible constitutional element in persistent neuralgias, headaches, annoying skin affections, wandering "growing pains" in the boy or girl at school. Every oculist of experience knows that properly selected glasses do not always overcome the disturbing influence of hyperopia or asthenopia. How often, too, in women are we apt to relegate the innumerable affections of the nervous system to that "dust bin" called hysteria, when we may, with perhaps greater scientific accuracy, find their cause in latent gout? Many of these affections and their congeners may be modified by judicious diet and a properly arranged hygiene.

Diseases of the ocular tissues dependent on scrofula, tuberculosis, and malnutrition, are so allied in their pathological exhibits and clinical behavior that they may be placed in one group, so far as our purpose is concerned. It is not necessary to devote much time to their consideration here, as they are so well understood. To name them in an anatomical category would be to index nearly all the diseases of the ocular system, from the lachrymal apparatus and lids in front to the periosteum of the orbit behind, in which the various tissues are deficient in tissue-builders. The external diseases of the eye are familiar to every practitioner and need no revision at my hands. Tubercle of the conjunctiva, iris, choroid, and retina, retinitis due to pernicious anæmia, etc., are rare and unique exhibitions of a common diathesis, and may be subjected with more or less success to the same rules of therapeutics, diet, and hygiene. The indications to be fulfilled in the main are not only to improve the nutrition by a better digestion, but to increase the body weight. Food should be fine, not coarse. Milk should be the staple, as also eggs. Easily absorbable fats, as cream, butter, and oil, are of especial value. Animal food should predominate over vegetable. The two first classes of constituent elements should enter almost wholly into the diet, viz., proteins or albuminates, and fats or hydro-carbons. The greatest care should be exercised to keep up a good digestion and assimilation—delay is the chief source of trouble in the management of these

[1] Gowers: Medical Ophthalmoscopy.

[1] Du Régime Alimentaire, p. 429.

cachectic cases. Weir Mitchell claims as to the dietary of anæmic people that "the loss of fat (flesh) nearly always goes along with conditions which impoverish the blood; and, on the other hand, the gain of fat, up to a certain point, seems to go hand in hand with a rise in all other essentials of health, and notably with an improvement in the color and amount of the red corpuscles. . . . To gain in fat is nearly always to gain in blood."

I cannot close without a brief reference to certain precautions in intra-ocular operations, which pertain to the subjects of diet and hygiene in eye diseases. Unless such an operation within the eye must by necessity be performed without delay, the previous habits as to diet and beverages should be carefully noted, and corrected if necessary; and the urine should be carefully examined. Albuminuria and glycosuria should be detected, if present, and a proper dietetic and hygienic course prescribed. My personal feeling is that a surgeon who fails to do this fails to do his duty by his patient, and also to protect himself. It is a well-known fact, that of presumably healthy persons nineteen per cent. show albumin on the first examination, amounting to from a trace to three per cent.[1] Deducting the transient cases, there will remain a definite number of cases of albuminuria in a presumably healthy selection of individuals—about fourteen per cent. The importance of knowing this in advance is unquestioned. Cataract extraction in patients with albuminuria and glycosuria must, necessarily, be attended with complications, especially as to the healing of the cornea, bruising of the iris, and convalescence. In a group of seventeen extractions in private practice last year, one of which was a double extraction at one sitting—the ages ranging from forty-seven to eighty-nine years—two of the sixteen patients showed albuminuria, two had enlarged prostate, one old cystitis, one diabetes with polyuria, and one prolapse of vagina and uterus with polyuria. All of these patients had been well-fed for years, but all were, so to speak, "prepared" for the operation by a system of diet and hygiene, so that in no case could it be said that convalescence was complicated by any serious accidents or delays. Each one had a nurse trained to the management of cataract-extractions. The poorest vision was $\frac{20}{100}$, and the best was better than $\frac{20}{20}$, which occurred in an eye myopic to the degree of $\frac{1}{4}$. "Training" for cataract-extraction is as essential as preparing for any other great surgical procedure; and we cannot be too careful in the special indications found present, and in the means of their fulfilment previous to operation.

In closing this rather lengthy paper on the proper management of diet and hygiene in this field of medicine, I take the liberty of quoting the following sentence of Sir Henry Thompson, whose opinions in diet, as in surgery, medicine, and art, are entitled to weight. He writes of improper dietaries: "I have come to the conclusion that more than half the disease which embitters the middle and latter half of life is due to avoidable errors in diet, . . . and that more mischief in the form of actual disease, of impaired vigor, and of shortened life accrues to civilized man . . . in England and throughout central Europe from erroneous habits of eating than from the habitual use of alcoholic drink, considerable as I know that evil to be."

In Eczema there are three groups of sequences: 1. Unknown primary changes in the cells 2. Arrangements to dispose of the adventitious matter from the blood. 3. Altered chemical action in the epithelium—which sequences have certain forms which appear on the surface of the skin, as redness, swelling, papules, vesicles, etc., and desquamation of cells. In the management of eczema three objects are to be specially aimed at: 1. To sterilize the skin. 2. To aid the removal of the adventitious fluid and cells. 3. To help the formation of the new horny cuticle, and to protect the skin during, and for some time after, its formation.—ROBERTS.

THE RELATION OF SYPHILIS TO GENERAL PARESIS.[1]

BY FREDERICK PETERSON, M.D.,

CHIEF OF CLINIC, NERVOUS DEPARTMENT, VANDERBILT CLINIC, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; PATHOLOGIST TO THE NEW YORK CITY INSANE ASYLUMS.

THE question of the position taken by syphilis in the etiology of dementia paralytica is one that has been attracting great attention among syphilologists and alienists of late years. No fewer than seventy authors have contributed to the elucidation of this problem, and the references to it in the indices of journals devoted to neurology and pyschiatry multiply year by year in a geometrical progression. The majority of the contributions mentioned treat of the subject from a statistical standpoint, and it would seem that sufficient data have been accumulated to fully satisfy all inquiries regarding that particular. Naturally the first point upon which precise information was needed was as to the percentage of cases of general paralysis with a history of syphilis, and we are now in a position to supply it fully. Although these statistics differ at times very materially, yet the results in the main agree. I have placed below, in alphabetical order, a list of the more important authors I have consulted, and the percentages of syphilis found by them in their cases of paralytic dementia:

	Per Cent.		Per Cent.
Ascher[2]	34.7	Mendel[13]	76
Binswanger[3]	64	Nicoulai[14]	13
Bannister[4]	88	Obersteiner[15]	21.6
Cuylits[5]	75	Oebeke[16]	53
Folsom[6]	66.6	Pontoppidan[17]	52
Fuerstner[7]	32	Regis[18]	70–76
Geill[8]	78	Rohmell[19]	76
Jespersen[9]	77	Savage[20]	70
Jacobson[10]	52	Snell[21]	75
Kaes[11]	17	Thomsen[22]	62
Lange[12]	51	Ziehen[23]	33

Kjellberg[24] has taken the stand that all cases of general paralysis are of syphilitic origin, that the cases are affected either congenitally or through acquisition. But this author stands quite alone in his assertion, and is not justified by observations or facts in taking this position.

My own statistics are rather questionable, as are all obtained from large public asylums to which patients are taken in stages of the disease too far advanced for them to give trustworthy information regarding themselves, and whither they are generally brought by relatives or officers unacquainted with such an etiological factor in their histories. There were admitted to the Hudson River State Hospital for the insane 287 cases of general paresis. In 55 of these syphilis was definitely ascertained to have preceded the disorder. In the remaining 232 it was either absent or unascertainable. Actually, then, only nineteen per cent. were found to be syphilitic, but assuming that one-half of the others were affected, the total

ratio would be in the neighborhood of sixty per cent. of the cases.[1]

At public dispensaries we see these cases in the earliest stages, when histories may be more exactly obtained, and I have gone over the patients received at the Vanderbilt Clinic with the following results: Total of cases observed, 40; definitely syphilitic, 10; definitely not syphilitic, 12; unascertained, 18. Taking the 22 cases in which the exact facts were obtained we have 45.4 per cent. certainly syphilitic, and 54.5 per cent. certainly not syphilitic.

From an examination of all of the figures collected above from various sources, it would, perhaps, be fair to assume that about sixty to seventy per cent. of all cases of general paralysis have a syphilitic history. By a comparison of statistics of the relation of syphilis to all other forms of insanity, which I have estimated to be from six to ten per cent., we have the further fact that syphilis is seven to ten times as frequent in dementia paralytica as in insanity in general.

The fact is thus established beyond dispute that syphilis is a striking etiological factor in general paresis, but that thirty to forty per cent. of the cases are not syphilitic. It is therefore an important but not exclusive etiological factor.

A much more difficult problem is to determine the exact relationship between syphilis and general paresis. Is it a direct cause or merely a contributing agent? Is it in syphilitic cases a post-syphilitic affection, or is foregone syphilis merely a predisposing factor? This problem may be examined from several stand points. In the first place we have the rather remarkable statistics of Lewin[2] of 20,000 cases of syphilis, one per cent. of which became insane, and in which not a single case of general paresis developed. Then we have the further fact to which I have elsewhere alluded[3] that among the native Egyptians, where syphilis is one of the most widespread of disorders, no case of general paresis has as yet been reported, and in the asylum at Cairo, which I visited a few years ago, not one such case was to be found. It is significant, by the way, that alcoholism is seldom or never observed among them, the drinking of spirituous liquors being interdicted by the Koran. Such facts as these it is impossible to reconcile with a hypothesis ascribing to syphilis the direct causation of paralytic dementia.

Again, from the pathological stand-point, it is well known that the direct invasion of the brain by syphilis is characterized by changes in the blood-vessels (endarteritis obliterans), by the formation of gummata, or by diffuse meningeal infiltration (specific leptomeningitis or meningo-encephalitis). The first and third of these processes are most frequent in and about the base of the brain. The second is more common in cortical regions. On the other hand, in general paralysis we have a chronic meningitis of the convexity with atrophy of the cortex, and the processes in this disease and in syphilis are quite distinct, although there are cases in which a syphilitic meningo-encephalitis may closely simulate symptomatically dementia paralytica. The pathological processes are different. Not long ago Binswanger[4] gave the details of two autopsies in which gummatous and arterial syphilitic processes existed side by side with the pathological changes of general paresis; and Zambuco, Westphal, Ludwig Meyer, and others have reported similar cases. The coexistence of two distinct pathological processes does not prove the dependence of one upon the other. Kiernan[5] has lately reported nine cases of dementia paralytica in which syphilis was contracted after the development of the mental disorder.

There are some who argue that tabes and general paresis are frequently associated, and that tabes being a form of syphilitic disease, general paresis in consequence must owe its origin to syphilis. Thus Sachs[1] says: "The very frequent development of tabes after dementia paralytica, and of dementia paralytica after tabes, proves the close relationship between those two diseases; and since tabes is beyond a doubt a form of syphilitic disease, there is sufficient ground for thinking that dementia paralytica bears the same etiological imprint."

Now there are two points that should be taken into consideration with regard to this statement which I believe to be reasonably well founded. First, if the two diseases have the same etiological imprint, there ought to be a close correspondence in the percentages of syphilis in relation to each. But the consensus of opinion seem to be that a history of syphilis is found in only sixty to seventy per cent. of cases of general paresis, whereas in tabes the percentage is placed by Fournier at ninety-one to ninety-eight per cent., by Erb at eight eight per cent., by Rumpf at eighty to eighty-five per cent., and by Sachs himself at over ninety per cent. The Vanderbilt Clinic statistics are significant in regard to this point, for the histories were carefully investigated in both tabes and paralytic dementia, and the cases were all drawn from the same population. As stated above, of 40 cases of general paresis 10 were syphilitic, 12 not syphilitic, and 18 unascertained. Of 83 cases of locomotor ataxia 51 were syphilitic, 20 not syphilitic, and 22 unascertained. Of the 71 cases of tabes of whose specific history we have exact data over seventy-one per cent. were syphilitic and over twenty-eight per cent. not syphilitic. That is, then, among cases equally well studied and from the same sources 45.4 per cent. of general paralytics were syphilitic and seventy-one per cent. of tabetics.

Secondly, I should not at all agree with the statement that there is a "very frequent development of tabes after dementia paralytica, and of dementia paralytica after tabes," for it has been my experience that such cases are very few, and most men with a large asylum experience would, I am sure, coincide with this belief. They are striking when they occur, but they are rare. I am not alone in the statement of this opinion. At a meeting of the Deutsche Naturforschr. und Aerzte,[2] September 19, 1889, when Strümpell claimed that syphilis was always the cause of tabes, and, analogously, of general paresis, Mendel stated that, while he agreed with him in regarding syphilis as the most important cause of tabes, he would not identify the processes as the same, for only in a small number of cases of dementia paralytica was there gray degeneration of the posterior columns, and, on the other hand, only a few cases of tabes developed general paresis.

Then, too, in cases of paralytic dementia with tabetic symptoms, the nerve-fibres of the posterior columns are often little if at all implicated.[3] Hence it seems to me that in the present state of our knowledge an argument for a syphilitic etiology of dementia paralytica, based upon the grounds of a close relationship between tabes and general paresis has but little force.

One of the facts which has been employed against the opinion that this disease is a late form of specific disease, is the absolute futility of anti-syphilitic treatment. In every form of cerebral syphilis proper, whether gummata, meningeal infiltration, or even specific arteritis, we are enabled often to accomplish a great deal of good by vigorous and systematic treatment; whereas, in general paresis, even when a history of syphilis is clear, no appreciable effect is produced by anti syphilitic remedies.

We do have mental disease immediately due to syphilis —forms of hypochondriasis, mania, melancholia, dementia, and occasionally a syndrome closely simulating dementia paralytica (pseudo-general paresis). But typical dementia paralytica, in my opinion, has no immediate or late relation to syphilis as a direct cause. Syphilis is a

[1] I am indebted to Dr. Langdon for his aid in obtaining these statistics.

common etiological factor, but only in the sense of its being a predisposing cause. It prepares the soil in more than half of the cases for the development of dementia paralytica, this disorder having its direct causes in alcoholism, sexual excesses, and overstrain of the mental functions. The higher nervous elements are rendered prone to degeneration by the forerunning specific disease, which, as is well known, gives rise to a cachexia, with changes in the constitution of the blood. Thus Neuman and Konried[1] have systematically examined the blood in two hundred cases of syphilis, both in early stages and frequently after the lapse of years, finding the hæmoglobin diminished from fifteen to thirty per cent. In old and untreated cases the diminution varied from forty-five to seventy-five per cent.

My study of the subject leads me to submit the following brief conclusions:

1. A history of syphilis is found in sixty to seventy per cent. of cases of general paralysis of the insane.

2. The fact must not be lost sight of that in thirty to forty per cent. of these cases no history of syphilis, congenital or acquired, is to be found.

3. Antecedent syphilis is seven to ten times more frequent in general paralysis than in other forms of insanity.

4. Syphilis is therefore to be looked upon as a frequent but not constant factor in its production.

5. But paralytic dementia is not a form of specific disease, not a late syphilitic manifestation, nor is it a form of degeneration depending upon the syphilitic poison for its origin.

6. The relationship of syphilis to general paresis lies in the facts that it is a wide spread disorder in all communities, that it weakens the constitution and vitiates the blood in many whom it infects, and that the system is thus prepared in many cases for the direct operation of the final etiological factors of general paresis, viz., alcoholism, excessive venery, heredity, and mental overstrain and excitement.

ON VACCINATION.

By ALVAH H. DOTY, M.D.,

CHIEF INSPECTOR CONTAGIOUS DISEASES, HEALTH DEPARTMENT OF CITY OF NEW YORK.

To one who has carefully investigated the subject, it is evident that the people of this country are not properly protected by vaccination. The apathy shown in this matter is surprising when the large mortality from small-pox in the unprotected is considered, as well as the simple manner by which protection may be afforded. Many children remain unvaccinated as late as the fifth or sixth year, and revaccination receives practically little consideration. It is the latter which in a great measure is responsible for the presence of small-pox in this city.

It may not be amiss at the present time to review briefly the history of vaccination, with a presentation of statistics and such practical points as may be of interest to the profession.

Edward Jenner, the discoverer of vaccination, was born in 1749 in Berkeley, Gloucestershire, England. Early in life he showed a predilection for natural history, the preparation of zoölogical specimens, etc., and apparently had resolved to follow this occupation. It was decided, however, that he should enter the medical profession, and he was apprenticed to Mr. Ludlow, a surgeon of Sodbury, near Bristol. It was during this period that the power of vaccination was unfolded to him. He had learned of the tradition existing among the people employed in dairies, that those whose hands became infected as the result of milking cows having an eruption about the teats and udder, known as "cow-pox," were protected against small-pox. It seems strange that this report had not received greater attention, but the indifference of the people generally to traditions, and the reticence on the part of owners of dairies to furnish any information which might injure their business, may partly account for it. It did not escape the observation of Jenner, who for almost thirty years, carefully and patiently investigated the subject, and having demonstrated the protection afforded by vaccination to his entire satisfaction, gave to the world, in 1798, his description and results of vaccination in a paper, entitled "An Inquiry into the Cause and Effect of Variola Vaccina." During the period of his investigation he did not try to conceal his discovery, but freely discussed it and invited help, but met with nothing but indifference and discouragement. Even John Hunter, under whose care Jenner, as a favorite student, studied while in London, and with whom he lived for two years, was not impressed with the importance of vaccination; he occasionally spoke of it to his friends and referred to it in his lectures, but nothing more. Undaunted, Jenner continued his work, and at last, on May 14, 1796, vaccinated James Phipps, eight years of age. The operation was successful, and in July of the same year the boy was inoculated with lymph, taken from a small-pox vesicle, and as Jenner predicted, no result followed. The disappearance of cow pox retarded the investigation until 1798, when vaccination was repeated. In the meantime he had gone to London to continue his work, but it was three months before a vaccination was performed in that city. This was done by Mr. Cline, a surgeon connected with one of the hospitals, who vaccinated a boy suffering from hip disease, not so much as an evidence of his belief in its protective influence, as in the hope that it might prove to be a good counter-irritant. Other vaccinations followed, and the success of the new discovery became assured. Vaccination spread rapidly throughout England and the Continent; not, however, without considerable opposition and many annoyances to Jenner, principally on account of the ignorance displayed on the part of those who vaccinated, and the worthless quality of the virus used.

Vaccination was introduced into the United States in 1800, by Dr. Benjamin Waterhouse, of Boston, and in this city by Dr. Valentine Seaman, who, on May 22, 1801, vaccinated several persons with lymph obtained from the vesicle on the arm of a servant of Governor Sergeant, who was vaccinated in Boston by Dr. Waterhouse, and arrived here before the eighth day. In January, 1802, an institution for the purpose of free vaccination was established in this city, with Dr. Samuel Scofield as resident surgeon. This was subsequently merged into the New York City Dispensary.

Jenner continued his work more or less actively. The Royal Jennerian Society, over which he presided, was established in 1802, but owing to dissension among its members this association failed in 1808, and was succeeded by the Royal Vaccine Establishment. The latter part of Jenner's life was spent in Berkeley, where he died on January 26, 1823, of apoplexy.

There is probably no subject the statistics of which are more voluminous and convincing than those relating to vaccination. A few of them may be of interest, as showing the marked change in the frequency and mortality of small-pox before and after the introduction of vaccination.

In the city of London, between the years 1790 and 1800, the population being about 250,000, there were recorded an average of 1,780 deaths annually from small-pox. In the same city, between 1855 and 1868, the population being ten times greater, the records show an average of 729 deaths annually from small-pox. If the mortality from small-pox in London at the present period was equal to that of the prevaccination era, there would be annually 28,500 deaths from this disease. The following table shows the number of deaths from small pox in London per 100,000 inhabitants before and after 1800.

	Average.
1790 to 1800	712.0
1855 to 1868	30.4
1875	1.3
1876	20.8
1877	71.1
1878	38.8

	Average.
1879	12.1
1880	12.5
1881	61.9
1882	11.1
1883	3.4

In Vienna, between 1790 and 1800, the average number of deaths annually from small-pox was 835; in 1801, 164; in 1802, 61; in 1803, 27; in 1804, 2.

From the records of interment in Trinity and St. Paul church yards, in this city, it appears that there were 5,756 burials in these cemeteries between the years 1785 and 1800. Of these, 610, or one-tenth of the entire number, died of small-pox. During the years 1805 and 1806 there were 4,595 burials; of these, 110, or one-fortieth of the entire number, were deaths from small-pox.

Werner, in speaking of the helplessness of the people in the prevaccination period, says that in non epidemic years one-tenth of all mortality was from small pox, and in epidemic years, which occurred every third or fifth year, one-half of the mortality was due to this disease. One-third of the babies born died before the end of the first year, and those who were affected with small-pox and survived it were either blind or otherwise disfigured. In 1734 two-thirds of the entire population of Greenland died from small-pox.

Jenner believed that one successful vaccination was sufficient for life, and he regarded the cases of small-pox occurring a number of years after a primary vaccination as being due to unsuccessful operation. The necessity for revaccination did not become apparent until the latter years of his life, during which time he had practically given up his active investigation. About the time of his death, however, it became a well-recognized fact that small-pox was occurring in those who had been successfully vaccinated in childhood, and that the protective power of vaccination became diminished about puberty or before. Revaccination was made compulsory in Russia, Sweden, Denmark, and Bavaria in 1838. It was also made compulsory in other countries of Europe. Statistics then began to show the value of the secondary vaccination. Hein found that in five years, among 14,384 revaccinated soldiers in the Wurtemberg Army, but two cases of small pox occurred, and among 30,000 revaccinated civilians there were also but two cases of the same disease recorded. During this period, however, there were recorded 1,674 cases of small-pox in the same section of country. Since 1834, when systematic revaccination was begun in the German army, nearly all the cases which have occurred have been recruits who had not yet been vaccinated. Marston states that during his service of thirty-two years in the Small-pox Hospital in London, every servant and nurse was vaccinated on first entering the institution, and during this service none of them were affected with small-pox.

Primary vaccination, but not revaccination, is compulsory in England, while in Germany both are compulsory. The following table from Gerstacker shows the marked effect of revaccination.

Deaths from Small-pox per 100,000 Inhabitants.

	1875.	1876.	1877.	1878.	1879.	1880.	1881.	1882.	1883.
Primary vaccination, compulsory. In London	1.3	20.8	71.0	38.8	12.1	12.5	61.9	11.1	3.4
Primary and revaccination, compulsory. In Berlin	5.2	1.8	0.4	0.8	0.7	0.8	4.7	0.4	0.3

There were 384 cases of small-pox reported to the Health Department of this city during 1892; of which 232 were over fifteen years of age. Thus far, in 1893, there have been 415 cases reported, of which 274 were over fifteen years of age. The percentage of cases over fifteen years of age is so large that it would indicate that these people had not received the benefit of revaccination. An investigation of the cases showed this to be a fact, the history given by the patients referred to, and the presence of at least one good scar in most cases, indicated that they had received the benefit of a successful primary vaccination; the statements made by these people relative to later vaccinations were imperfect and very unsatisfactory.

As might be expected, a large per cent. of the above number were mild cases, made so by the protecting influence of the early vaccination. Still these cases are, as a rule, the most dangerous to a community; the eruption frequently being very slight and with no pronounced constitutional symptoms, they mingle with others and scatter the contagion broadcast. A very striking instance of the value of revaccination occurred during the recent outbreak of small-pox. Toward the latter part of August of this year, 8 cases of this disease were discovered in the lower part of the city; they had been regarded as measles and no quarantine observed. New cases soon followed these, and it left no doubt but that others would occur. The infected district included "Cherry Hill," which, as it is well known, is in some portions densely populated, the people being crowded into small and old-fashioned houses, some of which open into alleys, oftentimes with an entire family occupying one room, and with very little attention given either to personal or general hygiene. A number of vaccinators were assigned to this district and began a house-to-house vaccination. The houses were visited night and day in order that all the tenants might be found and vaccinated. Fully three fourths of the cases of small-pox removed from this locality were adults, and the work of the inspectors consisted principally of revaccination; as a result, the outbreak, which at the beginning bid fair to become an epidemic, was entirely under control within a short time. The effect of the good work accomplished at this period is well illustrated by the following table:

Section of the City in the Vicinity of "Cherry Hill."

Date.	Number of cases.	Date.	Number of cases.
September 1 to 7	8	October 20 to 26	3
" 8 to 14	3	" 27 to November 2	3
" 15 to 21	18	November 3 to 9	0
" 22 to 28	16	" 10 to 16	1
" 29 to October 5	5	" 17 to 23	0
October 6 to 12	7	" 24 to 30	0
" 13 to 19	7		

It is the necessity for better protection against small-pox that has led the Health Department to push vigorously the work of vaccination and revaccination in this city, and the department has endeavored in all cases to co-operate with and gain the approval of the medical profession in this important matter. The work is done at the public expense, and is a public measure of safety; and it is the duty of the Health Department to respond to all requests for vaccination, whether it is from the rich or poor.

The Bavarian statistics given by Dr. Gerstacker as to the relative mortality from small-pox in the unvaccinated, in those who have been once successfully vaccinated, and those who have been successfully revaccinated, indicate the following result:

Of 1,886 cases reported, there were:

	Mortality per cent.
148 unvaccinated	44.6
1510 one successful vaccination	12.6
226 revaccinated successfully	6.1

Children should be vaccinated prior to the third month, unless contra-indicated by some acute disease, diarrhœa, cutaneous diseases, particularly of the vesicular type, as herpes, eczema, and intertrigo; in fact, Jenner's rule "to sweep away all eruption from the skin previous to inserting the lymph" is still a safe guide. These eruptions have been known, according to Seaton, to interfere with variolous inoculation. Children are very susceptible to small pox, and if exposed to this disease and unprotected, should be vaccinated at once; this may be done on the day of birth with satisfactory result.

The age at which revaccination should be performed

cannot be definitely settled, although there is no doubt that puberty is a period during which time the susceptibility to small-pox is marked, and it may be accepted as a rule that revaccination should in all cases be performed between the age of ten and fifteen years. In Germany it is compulsory between ten and twelve. A successful primary vaccination in childhood and a successful revaccination at puberty undoubtedly gives to the majority of persons the complete protection of vaccination throughout life. Unnecessary vaccination could be avoided if physicians would carefully observe each vaccination performed, and if successful, give a certificate stating the name and age of person vaccinated, whether a primary or a revaccination, date, etc. In this way an authentic history of each case could be obtained.

Horse-pox, a disease similar to cow-pox, was confounded by Jenner with the "grease," both of which affect the heel of the horse, but are of entirely different origin. He regarded cow-pox as a disease communicated from the horse to the cow by the hands of those who had the care of both animals. Inoculation performed with lymph taken from the vesicle of horse-pox has proved quite successful in the human being, and there seems to be little doubt but that horse pox (variola equina) and cow-pox (variola vaccina) are the result of variolus infection of these animals communicated to them in different ways. This susceptibility to variola appears to be confined principally to the cow and horse; other animals are said to be more or less susceptible, but the statistics in regard to this are insufficient for definite proof.

Inoculation with lymph taken from the vesicle of small-pox was in vogue at least one hundred years before vaccination. It was practised extensively in Constantinople in 1700, and introduced into England in 1821. That it rendered small-pox comparatively harmless (about 3 or 5 deaths per 1,000 persons inoculated) was undoubted. It, however, was a means of propagating the disease in the communities where it was practised, which was a fatal objection, and after having caused the death of a number of prominent persons it was made unlawful in 1840 by an act of Parliament.

The belief existed at one time that the vaccine lymph as it was further removed from its origin (the cow) became progressively weaker and weaker; this has been practically abandoned. The virus is undoubtedly as effective to-day as ever. Retrovaccination consists in inoculating the cow with humanized lymph.

Arm to arm vaccination, the method of Jenner and one that is still in use, is the surest way of obtaining a successful vaccination. In taking lymph from a vaccine vesicle either for arm-to-arm vaccination, or for charging quill or ivory points, or for filling capillary tubes, the following rules should be strictly adhered to. The child selected should be plump and well, with a clear skin and a perfectly satisfactory family history, the lymph should be removed about one hundred and sixty-eight hours after vaccination. At this time the vesicle is at its highest state of perfection, the lymph clear and transparent. The puncture should not be made at the base of the vesicle, as there is danger of incorporating blood with the lymph. It should be remembered that the structure of the vesicle is cellular and a number of punctures should be made in order to properly liberate the lymph, which may at once be applied to the scarified arm of the children who are to be vaccinated. This may be done either by the lancet, a glass rod, quill, or whatever will answer the purpose, provided its surface is smooth and clean. If the lymph is to be taken for future use it is generally kept on quills, or on ivory points. These should be used as early as possible, as they deteriorate rapidly and cannot be depended upon to retain their activity for more than two weeks, although they frequently produce typical vesicles after an interval of months. They should be carefully kept air tight, at an even temperature of 60° F. The non-observance of this rule is one of the principal reasons why virus frequently fails. The capillary tubes contain lymph for one or more inoculations. They are sealed at the ends by heat, a process which is said to affect the contents unfavorably. The scab or crust from a successful vaccination, which drops off between the twentieth and the twenty-fifth day, is generally used for transmission to hot climates, or in cases where considerable time will elapse before being used. Crusts are used by moistening a small piece with water and rubbing on the scarified surface. The lymph and crust for vaccination should never be taken from a revaccination but always from a primary vesicle. The foregoing relates to humanized virus. The comparatively slow manner in which it is collected has led to the adoption in this country of the bovine virus, which is easily secured in large amounts, and has proved to be successful. Since the introduction of vaccination, innumerable instruments for scarification have been devised, used, and abandoned as worthless. They cannot be kept properly cleaned, nor relied upon. No better or simpler method can be employed than that recommended by the Health Department of this city, which consists in the use of ordinary needles, which are new and removed from the package at the time of vaccination. A fresh needle is used for each vaccination, then thrown away. If the needle is fine and sharp, very little pain is experienced. The ordinary lancet is too sharp for proper scarification. If this instrument is preferred for scarification, its point should be blunted by rubbing it over very fine sand or emery paper. In this condition, and with a little care, a perfect scarification can be made.

The phenomena associated with a successful primary vaccination are as follows: From two to three days after the vaccination a papule appears, which by the fifth or sixth day becomes a vesicle, cellular in structure and having a bluish-white or pearly color, with a central depression. When the vesicle is very small it is round and symmetrical, but in this country, where the scarification is comparatively large, the vesicle has an irregular or fluted border due to the coalescence of a number of smaller vesicles. At the end of one hundred and sixty-eight hours after vaccination the vesicle has become fully formed and is plump and distended with clear lymph. At this period a ring of inflammation begins to surround the base of the vesicle, and for the next two days spreads in a circular form, and when fully developed is from one to two inches in diameter. It is often attended with considerable hardness and swelling of the subjacent connective tissue. This inflammatory ring is known as the "areola" and represents a successful vaccination, and may be regarded as almost pathognomonic. The areola begins to fade about the tenth or eleventh day. The lymph has now become opaque, and the vesicle is dry in the centre, and by the fifteenth day a hard brown scab is formed which becomes darker and falls off between the twentieth and twenty-fifth day. There is usually more or less constitutional disturbance, elevation of temperature, restlessness, and the axillary glands may also become involved. The constitutional symptoms, however, are not essential to a successful vaccination. A vesicular eruption occasionally occurs, which resembles varicella, with which it may be confounded. It does not, however, resemble the vaccine vesicle. This complication very rarely occurs in the adult.

The marked features of the vesicle following a successful primary vaccination do not as a rule appear in a revaccination, neither is the typical areola present, although considerable local inflammation may follow the operation. The latter appears as early as the third or fourth day. The axillary glands may be affected, and there is more or less constitutional disturbance. The scab becomes detached and drops off during the second week.

A fungoid growth having a raspberry appearance occasionally occurs in place of the vesicle, it remains two or three weeks and gradually disappears, generally leaving no scar. It affords no protection whatever against small-pox, although it is sometimes improperly regarded as a successful vaccination. This growth also follows a revaccination.

GLENWOOD SPRINGS, COLORADO.

By HENRY M. LYMAN, A.M., M.D.,
CHICAGO, ILL.

So far distant and so inaccessible are many of the most interesting features of American scenery, that the wearied citizen and the enfeebled invalid have found it easier to visit the springs and health-resorts of Europe than to attempt the passage of the enormous distances that must be traversed in order to get anywhere in the United States. It is, therefore, a pleasure to chronicle every fact that marks an increase in the number of home attractions and to note every improvement in the means of locomotion by which they are made accessible.

It has long been known that America abounds in mountain scenery that is unsurpassed by anything in Europe. But the old world resorts possess the great advantage of easy approach and of provision with every comfort that the tourist and the invalid can desire. From our maritime cities a voyage of a week conveys the traveller to the lakes of Ireland and England, whence it is but a step to the Alps and the Tyrol. No wonder, then, that every summer finds the Atlantic steamships crowded. It is a glorious experience thus to renew acquaintance with the sea-gods, and to visit the centres where civilization was ripened thousands of years ago.

But to this picture there is another side. The respectable citizen who blithely ascends the gangway plank at New York, only to be dragged out upon the quay at Liverpool a wretched, retching, hollow-eyed, and scaphoid wreck of his former self, may subsequently learn to admire the grandeur of London, the splendor of Paris, and the sublimity of Mt. Blanc, but he can be seldom induced to admit that they are a sufficient compensation for a week of cocaine, sodium bromide, and sea-sickness. For every such person the great improvements that are making every part of America accessible and comfortable are a positive benefaction. For him let me outline an itinerary that will lead him through some of the most remarkable scenery in the world to a place that is destined to become a favorite health resort.

Leaving the New York Central Railroad station by the "Exposition Flyer," which starts from Forty-second Street at 3 P.M., the tourist is hurried without a pause through the matchless vistas of the Hudson River, until Albany is reached. Here a dining car is attached, and by the time that a leisurely dinner has been discussed, the train is hastening through the fertile fields and among the lovely hills of Central New York. The brilliantly lighted city of Rochester is passed at bedtime. Buffalo is skirted at midnight; and at intervals during the hours of darkness the flashlights and colored beacons of the United States Lighthouse Service, fitfully illuminating a long line of surf upon white, sandy shores and projecting jetties, indicate the harbors of Erie and Cleveland and other lake ports. Sunrise reveals the prairies of Northern Indiana and Southern Michigan, and breakfast is scarcely finished before the vast inland sea, Lake Michigan, appears in full view. A cloud of black smoke gathers upon the western horizon; and at ten o'clock A.M., after one of the most comfortable and rapid journeys that modern transportation can afford, you step forth upon the streets of dirty, dusty, noisy, audacious, sky-scraping Chicago. There rest may be enjoyed, if repose be possible in such a throng, until the hour of 5 P.M., when the western trains depart on half a dozen different railways. Let us choose one of the more southerly lines. We roll over the level prairies of Illinois, rich in cornfields and teeming with horses, hogs, and cattle. At midnight the broad Mississippi is crossed, upon a bridge of iron that seems to stretch an interminable length into the impenetrable darkness beyond the river. Daylight finds us still among cornfields upon the billows of the rolling prairie, but now it is the State of Missouri; and soon we are upon another enormous bridge that crosses the valley of the Missouri, through which winds the broad and turbid stream that bears the mire of Montana to its destination in the Gulf of Mexico. Before noon we have left behind us the youthful and energetic Kansas City; we are upon the classic soil of what was once known as "bleeding Kansas." Here is Lawrence and there is Topeka, and a little farther we view the dwellings of Emporia. Here the border-ruffians and the Massachusetts colonists met in war to the knife during those old *ante-bellum* conflicts that now seem so dreamlike, so far away, so foreign to all modern civilization. It is the same smiling landscape, gay with prairie flowers and resplendent with an abundant harvest, that has absorbed the attention ever since quitting Chicago. But, as the afternoon wears away, the view insensibly changes its character. The rolling prairie gradually loses its billowy contour and slopes gently upward toward the west. The soil is an impalpable powder devoid of bowlders and gravel. The little gullies, washed out in the fields by the rain, exhibit strangely perpendicular banks, suggestive of the cañon formation of which we have heard. Occasionally appears a distant ridge, crowned with a vertical cliff that is surrounded by a talus of fallen rock and earth, as if it had been once an island in some pre-Adamite sea. Water grows scarce and the settlements are few and far between. At sunset, the aneroid barometer marks an elevation of fifteen hundred feet above sea-level. Before us lies the broad and shallow valley of the Arkansas River—just now an insignificant stream, meandering in the distance among the cottonwood trees that fringe its banks and mark out the apparently slight depression through which it flows. These are the vast plains where roamed the buffalo and the Indian before the advent of railways and white men.

All night long as we slumber lightly in the comfortable Pullman car, the rumble of the wheels indicates that we are steadily advancing up the valley. At early dawn the arid expanse of the great desert is in sight on either side of the narrow ribbon of green that conceals the stream. A belated coyote glances for a moment at the moving cars and then scurries away in search of his lair among the clusters of sage-bush. Queer little prairie dogs sit up on their tails and chirp courageously as we whistle past their burrows. Yonder winds a trail across the dusty plain; it is bordered with the skeletons of horses and oxen; and there is actually a "prairie schooner," a real old-fashioned emigrant wagon, slowly toiling through this scene of desolation. The stainless blue of the Colorado sky arches over the earth; and, as the sun rises upon the cloudless horizon, its purple rays light up the Spanish Peaks, far away in the southwest. Behind, and northward, coming rapidly into view until the entire western horizon is occupied by the glorious vision, are the gray foot-hills and the snowy ranges rising higher and higher beyond each other, till we are in full sight of the Rocky Mountains of Colorado.

Soon after breakfast a cloud of white smoke begins to gather between us and the foothills. It issues from the silver smelting works of Pueblo; and at an early hour in the forenoon our train is halted in that city. Here a delay of four hours gives ample time to ride over the town; to visit the Mineral Palace, as the citizens call the museum in which are exhibited specimens of the minerals for which the State of Colorado is so justly celebrated; to view the fine houses and elegant grounds that are replacing the desert wherever irrigation can be accomplished; and, above all, to admire the mountains that form the magnificent background of the picture.

Refreshed by an excellent luncheon, we resume our journey at midday. In and out among the foothills, as are called the terminal moraines of the ancient glaciers, we follow the ascending course of the Arkansas. At Cañon City the train tarries for a minute among the orchards and vineyards that border the track, and then plunges into the tremendous gorge through which the river escapes from the mountain range. For several miles the foaming torrent tears its way between almost perpendicular cliffs of syenite that form a cañon of which the floor is no wider than Broadway, while its walls are hundreds of feet high. Along the entire course of this

gorge the roadbed has been blasted out of the solid rock, excepting one point where the track is actually suspended over the water from iron rafters that span the chasm.

After the passage of the Grand Cañon of the Arkansas the mountains recede a little way from the river, and their altitude increases. Occasionally a broad and level meadow indicates the position of some Alpine lake, now filled up with the wash of the adjacent hills. Far away in the southwest rise above fourteen thousand feet the snow-capped peaks of the Collegiate Range, Mount Princeton, Mount Yale, Mount Harvard. We are rapidly ascending; and, as evening approaches, we sweep around the broad valley into which Leadville looks down from an elevation of ten thousand feet above sea-level. Here was the ancient *mer de glace* from which issued the glacier that once lay in the channel of the Arkansas, and ploughed its Royal Gorge. But glaciers and mountain lakes have long since disappeared, and through the broad meadow that lies in their place now trickle the meandering streamlets that form the head-waters of the Arkansas River. We have reached the backbone of America; and through a tunnel, many hundred feet in length, we pass beneath the crest of the Great Continental Divide, and are in the valley of the Eagle River, where the water flows westward to the Grand River and the Grand Cañon of the Colorado, through which it finally reaches the Gulf of California and the islands of the South Sea.

As the train rushes impetuously down the slope, we can see through the twilight, far up the mountain side, the burrows and the huts of the miners who are digging silver. Darkness soon veils them from sight, and the lamps in their cabins can be scarcely distinguished from the stars above the distant peaks. We are descending rapidly, and the roar of the torrent beside the track indicates an increasing flow of water as we advance. A little more than two hours after crossing the Divide, the needle of the aneroid indicates a descent of five thousand feet. Our car-wheels rumble through the tunnel that pierces the huge promontory around which sweeps the Great Bend of the Grand River; a sudden burst of electric arc-light illuminates the foaming rapids and the valley and the mountains—we have arrived at Glenwood Springs. All these varied and interesting sensations have been experienced within the period of three days and three nights of comfortable travel, while your Atlantic steamship passenger of corresponding date, rocked in his mid ocean cradle, still "lies howling."

A railway 'bus, of approved pattern, trundles us across the iron bridge that spans the river. Everywhere a blaze of electric light, by the aid of which we can see the foaming rapids, the broad pool of the swimming bath, the lawn terraces, and, finally, overlooking all, a stately Italian palace, built of red sandstone and Roman brick—the new Hotel Colorado. We are hurried from one surprise to another, as our party is ushered into the spacious corridor where at evening the guests assemble and listen to the music of a German quartette band, and watch the arrival and departure of travellers. There are visitors from every considerable city in the country. Englishmen of every variety abound. Here, fresh from the Columbian Exposition, come a German count and countess, followed by their body physician and body surgeon and a numerous retinue armed with rifles and other weapons of war. There goes a bright eyed professor of world-wide reputation, from New York; and, yes, it is he, the prince of scientists, von Helmholtz himself, who is promenading up and down the long corridor. Elderly ladies draw their easy chairs near the wood-fire that blazes in the vast, old-fashioned chimney. Occasionally, a Mexican sombrero looms up in the twilight, as its owner with jingling spurs saunters to the desk for a chat with the clerk. Young people in gala attire skip lightly over the polished floor of the ball-room, while the worshippers of the great goddess Nicotiana sip their coffee and burn incense upon the wide veranda outside. Throughout the house gas is unknown, and everything is resplendent with electric light. Out of doors, despite the moonless night, the scenery is most impressive. The building stands upon a hillside, and occupies three sides of a square, of which the fourth lies open toward the valley, the river, and the town. The broad court, thus formed, is bordered with brilliant flowers, and is carpeted with the greenest of turf, while from its centre springs a fountain of water that throws its jet one hundred and thirty feet into the air. In the morning sunshine the spray is filled with rainbows, but now at night its feathery films are lost among the stars that glitter like diamonds in a cloudless sky that seems as translucent at the horizon as in the zenith. Beyond the terraced lawns, at the foot of the hill, the vast swimming pool shines, and the gliding river shimmers in the electric light. Upon the opposite side of the valley the town of Glenwood covers the slope of the ancient moraine; while above and around us lie the mountains, couched like sleeping giants, strong and silent as the arch of heaven itself.

After a night of sleep such as seldom falls to the lot of a jaded citizen, morning arrives freighted with new and unexpected pleasures. In this arid desert a diet of canned peaches and fried ham would not have been a surprise; but, here, in an elegant hall, we find every comfort that modern civilization can procure. Ripe fruit, fresh from the garden, mountain trout, the like of which can be found only among the mountains, juicy beefsteaks, delicious cream, vegetables galore; all proffered in abundance with the daintiest service in the world—the most exacting epicure could ask for nothing more. All this luxury where, only six years ago, the affrighted settlers were holding on to their scalps, and roaring lustily for the United States Army to save them from the Indian tribes!

Thus fortified we sally forth upon the town—a little village of about one thousand inhabitants, but well-built, for Colorado abounds in beautiful building materials. The streets are wide, and will soon be shaded with a luxuriant growth of cotton-wood trees, urged forward by the moisture that reaches their roots from the sparkling streamlets that gurgle through the open gutters. Aside from the medicinal springs there appears no visible reason for the existence of this thriving settlement; but we learn that here is a favorite rendezvous for such of the mining population as find themselves with surplus funds at their disposal. The local daily newspaper assures us that here every luxury known to civilization can be enjoyed. The shop windows swarm with curios, and at intervals along the sidewalks little blackboards, chalked with apparently random figures, notify the passenger that at stated hours of the day the solution of certain aleatory problems will be here announced. The crisp morning air and the brilliant sunshine inspire everyone with life and hope; even the silver miners are cheerful. Well-dressed strangers drive about in open carriages; small boys coax the wilful burro into a surrender of his freedom; a troop of lively young Englishmen canter away to their polo-ground; and here, jogging along on their ponies, and exchanging nods and smiles with the leading citizens and ladies of the town, come a pair of cow-boys, looking as if they had been just now let loose from Buffalo Bill's Wild West Show. One of them, our informant whispers, is out on bail after an interview with the police, owing to a slight misunderstanding that had resulted in the sudden death of another man. "Shoot first, and then investigate, is the rule."

Well, then, let us return to the other side of the river. Here, at the foot of the mountain, are the famous hot springs, bubbling up along the bank of the stream. The largest source has been surrounded with a curb that encloses a pool, about twenty feet in diameter, where the water, at the temperature of 124° F., boils up with a strong and steady stream that flows through a broad conduit to the red sandstone bath-house and the great swimming pool, a few yards below. The water is beautifully transparent; it exhales a faint odor of hydrogen sulphide, and tastes like chicken broth. According to Professor

Charles F. Chandler, one United States gallon contains:

	GRAINS.
Sodium chloride	1,089.8307
Magnesium chloride	13.0994
Sodium bromide	0.5635
Sodium iodide	Trace.
Calcium fluoride	Trace.
Potassium sulphate	24.0434
Calcium sulphate	82.3861
Lithium bicarbonate	0.2209
Calcium bicarbonate	24.3727
Ferrum bicarbonate	Trace.
Sodium phosphate	Trace.
Sodium biborate	Trace.
Alumina	Trace.
Silica	1.9712
Organic matter	Trace.
Total solids	1,250.0411

From this analysis it appears that the water of the Glenwood Springs resembles that of Aix-la-Chapelle and the "chicken broth" springs of Germany. It is, therefore, useful in the treatment of those diseases that find relief at those springs. Syphilitic diseases of the skin and mucous membranes, arthritic diseases, cutaneous disorders, and chronic catarrhal inflammations are the principal ailments for which the baths and the internal use of the waters are indicated. The temperature and the taste of the fresh spring water are not disagreeable, and the baths cannot be surpassed. For delicate patients ample provision is made in the tub baths that occupy two floors of the spacious bath-house, while for all who can enjoy the luxury of a swim, the open-air natatorium affords a pool, five hundred feet long, covering more than an acre of space, constantly filled with water from the great hot spring, so that an almost uniform temperature of 85° F. is maintained during the entire year. As the spring water enters and leaves the pool at the rate of two thousand gallons per minute, its transparent purity never deteriorates. In midwinter, when the boys are skating on the frozen river, the natatorium is always warm and perfectly comfortable. It is impossible to give an adequate description of the beauty of the place. The construction of the bath-house alone involved an outlay of one hundred thousand dollars. The great pool is curbed with red sandstone, and its floor is paved throughout with hard red brick. The surrounding lawns are of that vivid green that is so characteristic of Colorado wherever irrigation is practised. The mountain stream that furnishes such delicious water to the Colorado Hotel and to the town, here feeds an array of fountains that fill the sunny air with rainbow-tinted spray, so that the adjacent landscape forms a pleasing contrast with the sombre hues that darken the arid slopes in the background. This aridity, however, forms one of the principal advantages of Colorado as a health resort. Dew is unknown, and rain seldom falls. The subjoined tabular record of observations by the United States Signal Service, at Glenwood, during the year 1889, illustrates this fact. It does, not, however, give any idea of the continuity of sunshine throughout the year. For days and weeks together the deep blue sky remains unflecked by a cloud; and the transparency of the atmosphere, unstained by dust or smoke, is like that of the oceanic belt within the tropics. For this, and for many other reasons, Colorado is remarkably attractive to all tourists and invalids who desire an out door life.

GLENWOOD SPRINGS, COLORADO.

Monthly Rainfall (in inches). 1889.

Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Total.

Mean Temperature (in Degrees). 1889.

Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Annual.
18.1	25.1	41.9	52.9	53.8	64.5	73.8	71.0	59.3	49.0	28.1	33.3	47.6

Having sufficiently medicated our mucous membranes and our cutaneous surfaces, and having visited a neighboring cavern in which the heated vapor that escapes from the crevices among the rocks is utilized for the purposes of a Russian bath, a choice of proceedings lies before us. The brain-weary and the invalid cannot find a more restful retreat than the Colorado Hotel. The student of natural science will find unceasing pleasure in tracing the formation and the degradation of these mountains under the successive influence of fire, ice, and water. For the sportsman, on slaughter intent, the vast highlands north of Glenwood afford the happiest of hunting grounds, where, as the above quoted daily newspaper asserts, even the lion (probably a harmless local variety) may be found. But for the majority of tourists the homeward journey cannot be long postponed. We can return by another railway route, giving a different view of the mountains, and crossing the Great Continental Divide at an elevation of eleven thousand five hundred feet by a series of zig-zag loops that leave the famous Horseshoe Bend of the Pennsylvania Railway quite out of comparison. Tarrying for a day at Manitou—a sort of American Chamounix—we may easily ascend Pike's Peak, where, at an elevation of fourteen thousand one hundred and forty-seven feet, under a cloudless sky, the greater part of the State of Colorado lies open to view. To the north, to the west, and to the south, at least five octants of the visual circle are filled with the ranges and peaks of the Rocky Mountains; while far away to the east the plains of Colorado and Kansas extend beyond the horizon. In midsummer and in September the higher peaks alone are powdered with snow. The lower ranges display the gorgeous hues of their many-colored rocks and cliffs, unstained by vegetation, dry and barren as a desert; in this respect differing widely from the Alps of Switzerland, and from the mountains along the line of the Canadian Pacific Railway. But this peculiarity gives to the scene a grandeur that is all its own. Furrowed and worn by ancient glaciers that have long since disappeared, the purple peaks sleep in the silent sunshine, filling to its utmost limits this vast grave yard of dead mountains, like an army of earth-giants fallen in battle and waiting for the twilight of the gods.

From the attenuated atmosphere of Pike's Peak to the lower levels of Colorado Springs and Denver, the transit occupies but a few hours. There we find large and beautiful cities. There we meet the transcontinental lines of traffic, over which we pass easily and rapidly, reaching New York once more within a fortnight from the day of our departure.

Chlorobrom in Sea sickness.—Dr. Arthur Hutcheson, writing to *The Lancet*, says that he used chlorobrom in all cases of sea sickness to which he was called while ship's surgeon on a voyage to and from New Zealand. He always gave it in three-drachm doses in the second stage of this distressing ailment, when retching, headache, depression, and sleeplessness were the prominent symptoms, the hour selected for administration being 10 P.M., in order to secure a good night's rest. The results were very satisfactory. The chlorobrom was always retained and was always followed by sleep (generally sound). The patient awoke much refreshed in the morning, with an appetite and able (except on one occasion) to eat and retain something light.

Prostatectomy.—The perineal operation is somewhat less severe, but decidedly less reliable than the suprapubic; it should rarely be preferred, unless there be urethral complications. In very feeble men it may still be elected.—KEYES.

COCAINE AND ITS USE IN ABDOMINAL SURGERY, WITH REPORT OF CASE.

By W. W. STEWART, M.D.,

COLUMBUS, GA.

Cocaine will often fill a need belonging to abdominal surgery. When the heart is profoundly weak from sepsis or other causes patients without its use could only be left to die, whereas guarded well by morphine, with atropia and nitrite of strychnia, its depressing effects upon the heart, and the excitation of the nervous system following its use are almost completely done away with. As illustrative of these facts the following case is reported:

On September 19th I received a call from Dr. Thomas W. Tuggle, to meet him for the purpose of examining a patient of his who was suffering from a large abdominal tumor. Patient a negress, forty-two years of age. Up to time of first appearance of this trouble, which was three years ago, had been perfectly well, and all functions normal. About this time she began to be troubled with some pains in lower portion of abdomen, and slight enlargement, more particularly of right side. This process remained almost dormant till nine months ago, when abdomen rapidly increased in size. Within a month from beginning of rapid increase breathing became very labored. Was compelled to sit up all the while. Intra-abdominal pressure became so great that only small quantities of food could be retained in the stomach at a time. Larger quantities would be immediately regurgitated. Lower extremities became slightly œdematous. Bowels regular. Digestion fairly good. Amenorrhœa had existed since the rapid increase in size of tumor. Though patient had never borne children and perineum was intact, she had developed from pressure a large rectocele and cystocele, protruding one inch from vulva. Measurement at sternum, two days before operation, 37 inches; two inches below, 42. At umbilicus, 39½ inches; four inches below umbilicus, 36. Distance from ensiform cartilage to pubic bone, 22 inches. On September 23d, assisted by Drs. Thomas W. Tuggle, Blanchard, and Griggs, the operation was begun. Ether was first administered. Pulse, when anæsthetics were begun, 120. In two minutes patient ceased to breathe, became insensible, and pulse went up to 200. Ether was immediately withdrawn. It was then decided to remove part of the fluid by aspiration, to give more room for respiratory movements, and about one quart was removed with an Allen's pump. After this patient breathed somewhat better, but pulse remained quite rapid and feeble. I then decided to do away with the ether and see what could be done with local anæsthetics. Three grains of cocaine hydrochlorate were used in a solution, injected subcutaneously and into the muscles over the area that would be occupied by an abdominal incision. At the same time there was injected one-quarter of a grain of morphine with $\frac{1}{100}$ of a grain of atropia, also $\frac{1}{30}$ of a grain of nitrite of strychnia, after which pulse dropped to between 90 and 100, full and regular. In seven minutes after injection of cocaine an incision four inches in length was made into abdominal cavity, from which four gallons of ascitic fluid were removed, and a fibro-cystic tumor of the uterus was exposed, extending to within two inches of sternum. The tumor had sprung from the posterior surface of the uterus, obliterating the cul-de-sac of Douglas, and stripping up the peritoneum from the rear, it being itself extra-peritoneal. Anteriorly it was covered by the small intestines with their mesentery. Small intestines were atrophied to a marked degree, only measuring one-fourth of an inch in diameter. Walls were thickened and a purplish blue in color. Mesentery was entirely devoid of fat, and resembled closely mosquito-netting in appearance. The intestines were so laced across the tumor that its removal was impossible, so abdominal wound was closed. Patient suffered no pain from beginning to end of operation, which lasted twenty-three minutes.

The reason this case is reported so in detail is to bring out the interesting fact of the marked intestinal atrophy, which, I think, was caused by pressure of tumor upon mesenteric arteries, and also for the peculiar position which the tumor sustained to the peritoneum and intestines.

In behalf of the use of cocaine I would say I have never performed an abdominal operation so absolutely free from shock. Pulse was much better at end of operation than at beginning. Patient talked quite freely during entire operation, expressing herself as much relieved by the removal of tension, and being enabled to breathe freely. Asked for food immediately on being placed in bed. Convalescence was perfect in every respect.

Progress of Medical Science.

Sphincterplasty.—Dr. Gersung puts on record two cases in which the function of the sphincter ani was restored after resection of the rectum. The unfortunate condition of a patient upon whom it has been necessary to establish an artificial anus is so well known as to make repetition unnecessary. The various apparatus intended to control the contents of the bowel are unsatisfactory. If the fæces are liquid or semi liquid they fail entirely, while if the motions are fully formed the bowel is so entirely relieved at each evacuation that apparatus has only a moral value. The success of the suggestion to use the abdominal or gluteal muscles in the formation of a new sphincter remains to be demonstrated. The patients upon whom the author operated were suffering from carcinoma of the rectum. After resection of the diseased portion it was found possible to draw the bowel down to meet the skin incision. The author then rotated the rectum on its long axis by catching, with a pair of forceps on either side, until the index-finger could be introduced only with some difficulty. The bowel was then stitched to the skin incision. Healing followed rapidly and perfectly. In the first case continence was complete. The second patient had some incontinence of liquid matter at first, but this was rapidly overcome. Digital examination before the patients left the hospital showed that the funnel-shaped contraction, caused by the twisting of the bowel, had changed to an annular constriction, giving almost the same resistance as the normal sphincter.—*Centralblatt für Chirurgie.*

Functional Valvular Insufficiency.—Dombrowski discusses under this heading incompetency at the mitral and aortic orifices, the valves themselves being intact. The mitral valve may be functionally incompetent (1) in obstruction in the arterial system; (2) in lesions of the cardiac muscle; (3) in nervous disease as chorea, hysteria, and in chlorosis when it is due to defective innervation or disturbed nutrition; and (4) in the acute infective diseases (*The British Medical Journal*). The author then records three cases, two of which were fatal. In these latter the insufficiency was due to atheroma of the aorta and disease of the cardiac muscle respectively, the valves themselves being healthy. In both these cases the murmur disappeared for a time during life with temporary improvement in the patient's condition, and in the third case no murmur was to be heard when the patient was discharged. This insufficiency is generally looked upon as due to distention of the mitral orifice itself, but this orifice is surrounded by a tendinous ring. Experimentally the author has shown that when water is introduced under pressure into the ventricle, the insufficiency is due to dilatation of the latter. Clinically, also, the instability of the insufficiency is against its being caused by over distention of the orifice. Dilatation of the ventricle is always present in these cases, and in this way the insertions of the papillary muscles are further away, so that the valves are unable to close the orifice. Thus the term functional insufficiency should be used instead of relative insufficiency in regard to the mitral orifice. The absence of a history of rheumatism, much

dilatation of the heart, a varying loudness of the murmur at each beat, and especially the occasional appearance of the normal sound in place of the murmur are points in diagnosis. The author also draws attention to the murmur being louder, or perhaps heard only during inspiration when the intrathoracic pressure is greatest. At the aortic orifice insufficiency may also occur without valvular lesion, but it is much rarer. Two such cases are related. The insufficiency is here relative. The dilatation of the orifice is due to increased pressure in the aorta, but an abnormal condition of the aortic walls is indispensable. The patient's age, the mode of development, the presence of arterio-sclerosis will help to distinguish it from the incompetence of endocarditic origin. Thus functional mitral insufficiency may arise without a permanent lesion, and may recover if the cardiac muscle can recover, but in relative aortic insufficiency there is a lasting and progressive lesion.

The Action of Electricity on Microbes.—The methods employed by M. d'Arsonval to determine the action of electricity on living matter are already known. The process consists essentially in passing a current through a solenoid, in the interior of which the substance to be experimented on is placed. MM. d'Arsonval and Charrin recently made some investigations as to the effects produced on microbes by the current, selecting for this purpose the bacillus pyocyaneus. A culture of this organism was placed in the solenoid. At the commencement of the experiment a tube of nutrient agar-agar was inoculated with two drops of the culture. After the lapse of ten, twenty, and sixty minutes, respectively, further cultures were made in different tubes, which were all placed in an incubator for some hours. An examination of the tubes then showed that a luxuriant culture of the bacillus had grown in each; the forms of the colonies had undergone no change and were similar to those grown in control tubes; the pathological characteristics appeared also to be the same. The color of the cultures, however, had been to some extent affected; for while in the first two tubes the organisms exhibited an intensely green color, which was scarcely less vivid in the second than in the first tube, the color in the third and fourth tubes was much less marked. These experiments seemed to show, then, that the electric current had some effect upon the organisms, although the action was not very marked. Further investigations in the same direction would be valuable and might possibly throw some light on the electrical state of the atmosphere as affecting the course of certain epidemics.—*The Lancet.*

Complete Prolapse of the Rectum; Amputation.—Dr. Walter Edmunds, of London, reports the following case in the November issue of the *American Journal of the Medical Sciences:* The patient was a single woman, aged twenty-five years. She had suffered for many years from a prolapse of the rectum, for which no treatment had been of any avail. It was decided to perform the operation of removing elliptical portions of the mucous membrane, and thus narrowing the orifice. After the operation, as long as the patient remained recumbent, the bowel retained its position, but on her getting about, the prolapse recurred and became as bad as before. Three months after this operation a second attempt was made. It consisted in excising on each side a considerable portion of the distended external sphincter and bringing the free edges together. But, as before, when the patient began to get up again, the prolapse recurred. Encouraged by the perusal of a successful case of excision of a prolapse of the rectum by Treves (*The Lancet*, February, 1890), the author decided to advise the patient to submit to a third operation, to which she consented. Under an anæsthetic, the patient was placed in the lithotomy position, with the pelvis well raised, to avoid, if possible, any prolapse of small intestine into the peritoneal pouch, which it was expected to encounter. The prolapsed rectum having been drawn well down, a transverse incision was made in front of the prolapse at the junction of skin and mucous membrane. On deepening this incision a pouch of the peritoneum was opened, and the extreme lateral boundary of this to the patient's left (and operator's right) was sought. Both the parietal and the visceral layer of the peritoneum (on the rectum) were divided in stages from left to right, the two layers sewn together, and in this way the abdominal cavity was shut off. Nothing was seen of the small intestine. The amputation of the prolapsed rectum, flush with the surface, was then completed; bleeding-points were secured and the mucous membrane was sewn to the skin all around. The amputated portion contained the greatly dilated sphincter and eight square inches of peritoneum, a prolongation of Douglas's pouch. The patient made a satisfactory recovery. She was last seen fourteen months after the operation. She was then quite well and could walk several miles. There was no prolapse, no incontinence of fæces, and no contraction of the orifice. The line of junction of the skin and mucous membrane had retreated somewhat upward, and at that level a band could be felt, suggestive of an internal sphincter, but it probably consisted only of connective tissue. Other cases of prolapse of the rectum treated by amputation are recorded by Partridge in the *Indian Annals of Medical Science*, 1871, No. 27; by Raye (at Calcutta), in *The Lancet*, July, 1886, and by Treves, in *The Lancet*, February, 1890.

Salacetol in the Treatment of Diarrhœa.—Dr. Bourget presents his studies upon this remedy, which is a combination of salicylic acid and acetol, and possesses all the chemical and physiological properties which make salol an intestinal disinfectant of the first rank (*The American Journal of the Medical Sciences*). It is a white crystalline powder, insoluble in cold water; is first decomposed in the alkaline fluids of the small intestine; the salicylic acid accomplishes the asepsis and the acetol is rapidly eliminated as acetone. This remedy contains seventy-five per cent. of salicylic acid, against the sixty per cent. of salol. It apparently eliminates the salicylic acid more rapidly in a solution of castor oil, because the latter provokes a more abundant secretion of the intestinal fluids. He has treated a large number of infectious diarrhœas, and on only one occasion was he obliged to resort to laudanum. The dose is thirty to forty-five grains in an ounce of castor-oil, taken in the morning, fasting. Rarely is it necessary to be repeated on the following day, although no inconvenience results should it be repeated. Under this dosage the sulphur compounds (indican, cresyl-sulphates, skatoxyl sulphate) are diminished and reach their normal (one-tenth of the simple sulphate) within three or four days, showing that disinfection is rapid. Good results were also obtained with this remedy in subacute and chronic rheumatism.

The Utility of Saline Enemata in Hemorrhage.—Dr. Warman refers to recent improvements in the treatment of patients bleeding to death, and more particularly to the beneficial results of saline enemata. The author enumerates the objections to the intravenous and subcutaneous methods, the principal difficulties in the former being the impracticability and the danger in the use of an excessive quantity, and in the latter the slow absorption of the injected fluid. Being unable to use either method in a case of abortion, the author attempted a rectal injection, which was very successful. Subsequently he treated twenty-eight patients in the same way, most of whom when seen were much collapsed from post-partum hemorrhage. The typical rigor (associated with the gradual rise of temperature) very quickly became evident, the pulse returning and the respiration becoming normal in all cases A teaspoonful of salt was dissolved in a quart of water having the same temperature as the room, this having a more rapid effect than a solution at a higher temperature. The author holds that the salt in itself possesses marked hæmostatic properties, in support of which he adduces various observations. The proceeding is without danger and the only drawback is the occasional

inability of the sphincter to retain the solution. This the author overcomes by placing the patient on one side, allowing the solution to flow slowly and then pressing on the cannula through the vagina. In severe cases this trouble was least frequent, as in these he found absorption to take place most rapidly. The author recommends the same treatment in all severe hemorrhages, excepting those from the intestine.—*Therapeutische Monatshefte.*

Clinical Department.

COMPLETE DENUDATION OF THE TESTICLES; RECOVERY.

By J. A. BAUGHMAN, M.S., M.D.,

NEOGA, ILL.

Within the last few months two interesting cases of erysipelas of the scrotum came under my observation, a report of which I hope may prove valuable to the readers of the Record.

The first was the case of a boy, twelve years of age. The scrotum was slightly bruised upon the horn of a saddle, after which the ordinary signs and symptoms of erysipelas supervened, the most prominent of which was a great distention of the scrotal tissues from serous infiltration.

The constitutional treatment employed in the case was the tonic supportive form; the local measures used being the free scarification of the scrotal integument, making about twenty half-inch incisions extending through the skin, from which a constant dripping of serum continued for four days. Over the perforated area a moist sublimated cloth was constantly applied, with the intention and apparent result of preventing suppuration, the danger of bichloride-poisoning by absorption being much lessened by the continuous exuding of serum from the cuts. Thanks to the scarification the case recovered without any disastrous results. It remained for the second case to show the merciless hand of disease and the surprising powers of the healing process.

Stephen W——, aged forty-three, of German descent, and good family history, in June, 1891, slightly scratched himself with a barbed wire midway between the anus and base of the scrotum, immediately on the raphē. The wound being very insignificant scarcely attracted his attention.

In a few days a so-called "Eclectic" was consulted for what afterward proved to be the premonitions of erysipelas, viz., headache, pyrexia, and general malaise.

The medical attendant's attention was not directed to the wound, which was now giving signs of inflammation and swelling in the direction of the scrotum.

The proneness of the scrotal tissues to abundant serous exudations was not wanting here, and the result was, in a few hours, an enormously distended sac. Instead of scarifying or leeching to reduce the abundant serous infiltration, poulticing was the treatment employed.

The *vis inertiæ* of the scrotal tissues being below par as compared with other soft tissues in general, the inevitable result was stasis and coagulation necrosis. The patient remarked that he had removed the dead tissue with his fingers, and that it looked much like flakes of coagulated egg albumin.

The loss of scrotal tissue was complete, extending well up to the pubis and about an inch along the lower side of the penis in the position of the raphē. At this stage the case fell into my hands. The raw testicles dangled between the legs. They were swollen to twice their normal size, their surface freely suppurating. The surrounding tissues had a malignant appearance; the angry-looking surface being honeycombed with small sinuses. The left inguinal region presented a severe lymphadenitis, from perhaps a simple infection, as no specific taint was visible in the patient or his nine healthy children. My belief from observation and investigation was that under proper treatment the wound would heal without any operative procedures. In private practice the medical attendant has more than the obstacles the case itself presents to surmount. Overcoming the opinions of the laity and machinations of jealous competitors in such a case is no small achievement.

Although in most cases leaning toward operative interference where such measures are justifiable, I treated this on the "expectant" plan. I doubted the possibility of nourishing a large enough piece of integument to cover the swollen testicles were I to attempt a plastic operation. The ragged condition of the surface and the danger of destroying the tunica albuginea or fibrous covering of the glands, and thus destroying the testicles, precluded the idea of curetting preparatory to anything like Thiersch's method of skin grafting.

My first attempt was to arrest the excessive suppuration. This I incompletely attained by the free use of boric acid, irrigating the parts every three hours with a saturated solution and then dusting the dry acid over the wound. Complete disinfection was impossible by this method on account of the many sinuses. After getting the suppuration to the minimum repair slowly began to manifest itself.

The acute erysipelatous invasion had now entirely subsided. The patient's general health at this time was fair to good, temperature normal, appetite fair, bowels slightly constipated. Healing for a week progressed slowly. The lymphadenitis in the left inguinal region was painful at night and showed a disposition to spread. The skin over the tumefaction was hyperæmic and adherent to the underlying tissues. The boundary line was poorly defined, fluctuation being nowhere perceptible. This complication gradually subsided under the application of heat and tincture of iodine. The scrotal tissues being largely of the connective variety are equalled in their aptness to slough only by the readiness with which they are reproduced, yet for a short period repair seemed to cease. In consultation with Dr. Clark, of Effingham, castration was decided upon. While waiting two days upon the subsidence of the lymphadenitis in the inguinal region, repair was again manifesting itself. The case now progressed favorably for a few days, when a hasty messenger announced that the sufferer was bleeding to death. Thinking it was the spermatic artery giving trouble I went prepared to castrate. Hemorrhage had ceased upon my arrival, examination revealing only a corroded vein. A bit of styptic cotton was applied to this and it gave no further trouble. From this time the case ran an uneventful career with the exception of suppuration in the tumefied inguinal region above mentioned. Repair rapidly advanced until now a tolerably roomy scrotal sac, perfectly healed, is the result. A slight degree of mania was observed in this case at various times, a condition noticed by several writers in grave testicular diseases.

The prolonged use of boric acid on this large, raw surface gave cause for study. At one time during its use the patient suffered a violent bloody diarrhœa, bloated face, and a very diffuse general erythematous eruption, all effects of this drug noticed by other writers. Discontinuance of the drug was promptly followed by relief. Boric acid being supplanted in the case by iodoform, repair was very much more rapid; arguing decidedly in favor of iodoform.

To recapitulate: 1. In overdistended scrotal tissues scarify freely to avoid sloughing. 2. The scrotal tissues though easily destroyed have a wonderful reparative power. 3. In complete denudation of the testicles, castration or plastic operations are not always the most imperative procedures. 4. The large veins occupying the scrotal region are liable to cause alarm from bleeding. 5. Mild mania is often noticeable in grave testicular affections. 6. Boric acid is not absolutely poisonless. 7. Iodoform excels boric acid as an application to granulation tissue.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

New York, December 9, 1893.

DANGERS TO STATE HOSPITALS FOR THE INSANE.

THE care of the insane in public institutions always vitally interests the people. They are willing to see the criminal punished and the tramp committed to the workhouse, but they resent the ill-treatment of the insane. For the latter class there is universal sympathy. No building is too costly for his residence if it conduces to his well-being; no luxury is denied him if it is essential to his happiness; no expense is spared for physicians or attendants if they can contribute to his recovery. The people of the State of New York have especially been distinguished for their generous treatment of the insane. They have provided the most costly hospitals for their residence in this or any other country; they have equipped these hospitals with every condition necessary for the physical comfort of the inmates; they have supplied them with every appliance which science could suggest for the proper treatment of insanity.

The last and most significant act of the people was the removal of the pauper insane from the poor-houses to the State Hospitals, in order that this wretched class of dependents might have the benefit of the better food, clothing, housing, and nursing of these institutions. The provisions of the Act show that the purpose of the Legislature was to provide an inexpensive but thoroughly commodious class of buildings for these poor-house inmates, in such relations to the State Hospitals as to come under their general management, and yet not to interfere with their special methods of administration. The fundamental idea of the projectors of the State Care Act was as follows, viz.: 1. Maintain the present State Hospitals for the acute insane, and perfect their arrangements, equipments, and management by every means necessary to the cure of those committed to them, in order that they might be made, in the highest and best sense, curative institutions. 2. On suitable farm lands, removed from the hospital, but not too remote to prevent direct and easy general supervision by the management of the hospital, erect a variety of comparatively cheap buildings, and thus create a colony, to which would be transferred the incurable inmates who now overcrowd the hospital wards, and the pauper insane of the poor-houses. It was believed, and we think justly, that if this policy was carried out, the existing State Hospitals, relieved of the incurable insane who fill their wards and greatly interfere with classification and discipline, would so improve their methods of treatment that a far larger percentage of recoveries would be secured than was hitherto reported or even deemed possible. At the same time there would gradually be organized a colony of chronic or incurable insane, under the management of each hospital, which would become largely self-supporting, and would, by means of industries, schools, discipline, and amusements utilize in a healthy manner every remaining faculty of each individual inmate. A system of lunacy administration based on these views, and intelligently carried out by the hospital authorities, aided by intelligent State supervision and advice, would have been worthy of the Empire State.

The question is beginning to be widely agitated among those interested in our public charities: What has been the effect of the execution of the State Care Act upon the State Hospitals, and upon the pauper insane who have been removed from the County Asylums? It is evident that there is a growing public sentiment adverse to the methods of administration of the State Care Act by the Lunacy Commission. It is alleged that not only have the pauper insane not been greatly benefited by the change from the County Asylums, but the whole procedure is tending to convert the State Hospitals into immense pauper establishments. The public prints report interviews with the Commissioners, detailing the economy with which they are now running the institutions; one has succeeded in diminishing the wages of employees, another has found a method of purchasing the food-supplies at cheaper rates, and a third has stricken from the supply-list that solace of a disturbed mind—tobacco!

These reports from the Commission are very familiar reading, for the same statements were formerly annually rehearsed at the meeting of the Superintendents of the Poor, who detailed with great minuteness their methods of keeping the insane poor at low rates. No reports come from the Commission announcing new and successful methods of curing the insane which they have introduced into the hospitals, nor that they have rendered these hospitals far more efficient in the cure of the acute insane by reforms in the management, better equipment, diminished crowding, or a higher grade of attendants.

We believe the State Care Act was a wise and beneficent measure, and if administered by a judicious and experienced body it would have accomplished a most important reform, both in the care of the poor-house insane and in the higher development of the resources of the State Hospitals for restoring the acute insane to health. But we are forced to the conclusion that the pauper insane transferred from the County Asylums will not be greatly benefited by the change, and that the State Hospitals, once the pride of the State, are rapidly deteriorating as curative institutions. We give this note of warning while it is yet possible to arrest the progress of an administration of the State Care Act, which will involve our hitherto greatest and most useful public charities in irretrievable ruin.

Perineal Section in Rupture of Urethra.—Permanent catheterization, by avoiding introducing the instrument too far into the bladder, and observing strict cleanliness by regular antiseptic irrigations, will be found to possess many advantages. Sutures are advised in closing the rent in the urethra.—WHITE.

BATTLE-FIELD AID.

The return from Europe of Medical Director of the Navy Richard C. Dean, after six months spent in the investigation of field hospital service abroad, leads us to anticipate some interesting data upon this very important question when his report is made. From what Dr. Dean has already said in a *Herald* interview it appears that Germany is the only power having a regularly drilled Hospital Corps. England seems to have made less advance in the matter of handling wounded soldiers than other nations, still clinging to primitive methods, while France does not seem to be much better off. Italy shows a praiseworthy spirit in pushing reforms, and, as is known, the king has recently given a prize of forty thousand francs for the best, most portable, and most improved method of rendering first aid to the wounded. The importance of some method of transportation not requiring too many attendants has long been recognized, but the problem of quickly, safely, and comfortably removing a large number of men to the field hospital remains to be solved. In this connection we would call attention to the Red Cross Ambulance recently introduced and described with illustrations in *The Lancet* of August 26, 1893. The carriage is mounted on half-elliptic steel springs, so that vibration is reduced to a minimum; the wheels are like those of a tricycle; two behind and one in front, lightly constructed and with rubber tires. A jointed hood fits over the litter, and this, it seems to us, might be made of some bullet-proof material. One man is sufficient to propel the ambulance, but unfortunately it gives accommodation to but one occupant at a time.

The improvement which suggests itself to our minds would be to utilize for this purpose a real tricycle, having seat, pedals, and propelling gear; then the patient having been disposed of, the attendant could mount the machine with the rolled-up litter suspended underneath or at the side, and quickly return to the field of carnage.

SUDDEN DEATH FROM HEART-FAILURE.

The frequency of heart-failure as a cause of death has caused much comment from the laity, and brought forth a certain amount of grim humor concerning the diagnostic errancy of physicians. For it has been assumed that in most cases of sudden death doctors give heart-failure as a cause, in order to hide their ignorance of the true complaint. This view of the matter is unjust. Boards of Health require the statement of the immediate cause of death, and naturally in most acute maladies, as well as in some that are chronic, it is failure of the heart. But, aside from this, sudden death due directly and indirectly to failure of the heart is not very uncommon. In an article in the *Boston Medical and Surgical Journal*, Dr. W. T. Councilman has gone over this question from the pathologist's point of view. Dr. Councilman does not consider cases of death due to the action of poisons or traumas; leaving out these, he enumerates the causes of sudden heart-failure somewhat as follows: First, emboli and thrombi developing in the heart or brought to it, and plugging its cavities; next, rupture of valves, or over-distention of the heart from too tight an aortic orifice; diseases of the coronary arteries, which lessen the lumen and cause degenerative changes in the muscle. As a result of this we have the so-called myocarditis, infarctions, and fatty degenerations. Rupture of the heart may occur from these last conditions, and rupture is not excessively rare as a cause of sudden death. Still, much the larger number of deaths in coronary disease is due to other causes than rupture of the muscle, and disease of the descending branch of the left coronary is most frequently present in these fatal cases.

Sudden death from heart-failure may be considered as most frequently due to coronary disease. Hence it is oftener seen somewhat late in life. Contrary to the usual belief, persons with valvular heart disease do not die suddenly, especially if it be the mitral valves that are affected.

A PLEA FOR THE "POOR MAN'S DOCTOR."

We feel disposed to say a word on behalf of him who, in a recent discussion on the dispensary question at the New York Academy of Medicine, was styled the "poor man's doctor," and declared to be on the average "either inexperienced, incompetent, or a scheming quack."

With this last statement we are disposed to take issue. Who is the poor man's doctor? It is, perhaps, somewhat difficult to answer this question, but we presume it is (in the sense of the discussion above named) the doctor who lives among the tenement-house population, and derives his income from practice among this class of our citizens. This definition is not, however, entirely satisfactory, for much of the tenement-house practice is done by men who live nearer the centre of the north and south dividing-line of the city.

The energetic efforts of the County Medical Society have practically cleared the city of illegal practitioners. The poor man's doctor, therefore, is a graduate of some regularly incorporated medical college. As such, he presumably knows something, and in the trial of the charge brought as to his being on the average inexperienced, incompetent, or a scheming quack, he is, be it remembered, the defendant and not the plaintiff. The *onus probandi* lies most emphatically on the side of his accusers.

Poverty and quackery do not always flourish on the same soil. The average quack practises medicine only because he sees more money in it than in other callings, and he finds his dupes not so much among the very poor as among the middle classes. The more intelligent and the well-to-do people are too enlightened to be taken in by his schemes. The poor have too little money for him to waste his energy on them.

Very many of our leading physicians who to day have "gilt-edged" practices began their work among the poor people. Their ten-dollar fees began on a fifty-cent foundation, and there are young men in New York to-day who are doing their largest amount of work among the tenement population charging a dollar a visit, which is, we believe, by common custom, the usual charge in the tenements. The vast majority of these men are not inexperienced or incompetent. A large proportion of them have served a regular term in some hospital. They have become attracted to this great city of ours, and have determined to cast in their lot with its citizens. They have no capital to keep them in idleness, and are obliged to settle where the expenses of living are small, and where

they can be reasonably sure of making both ends meet from the start. They are ambitious, and realize that to be thought worthy of many things they must be faithful in the few. They give, therefore, their best energies to the patients with whom they come in contact. They treat their cases just as well as their more fortunate brethren on the leading streets and avenues do their own, and considering the disadvantageous hygienic surroundings of their clientèle, their success is just as great. Twenty years from now they will stand among the leaders of our local profession. To call such men (and they perhaps make up fully one-half of the "poor man's doctor" category) incompetent and inexperienced is alike unjust and uncharitable.

The object of this whole argument against which we have been protesting is apparently to justify the attendance of the poorer classes upon dispensaries. Of worthy medical charity we have always been the friend, but the trouble has always been that, if reasonably well-to-do people are once engulfed in the dispensary maelstrom they never get out of it. They remain in the class which freely patronizes these institutions, and which has no business there. The attitude of the modern Board of Managers is one of eager welcome to all who can possibly be made to attend, and not one of discrimination between the worthy and unworthy. To justify this attitude by the assertion that the poor cannot find for a minimum fee competent physicians to attend them at their own homes, is contrary to fact, false in logic, and pernicious in its sociological relations.

News of the Week.

Planning a Hospital for Staten Island.—A number of ladies of Staten Island have arranged plans for the organization of a hospital, to be called the Staten Island Hospital. It is intended to open the hospital about the middle of next month. Nine physicians on the island have signified their consent to become members of its staff.

The Society for the Prevention of Cruelty to Animals recently arrested a member of a society whose object is the euthanasia of cats. One of the latter organization was caught chloroforming a cat in order to prevent it from starving to death. Philanthropy sometimes becomes a mental disease.

Official Declaration of the Contagiousness of Consumption.—Dr. Herman M. Biggs, chief inspector of the division of pathology and bacteriology of the New York Health Department, has presented a report to the Board of Health recommending the adoption of measures for the prevention of consumption, which he officially declares to be a contagious disease. He says that last year six thousand deaths due to tuberculosis were reported to the Health Department, and that the time has come when the health authorities should assume surveillance of consumption. Dr. Biggs makes these suggestions:

"That there be systematically disseminated among the people, by means of circulars, publications, etc., the knowledge that every tubercular person may be a source of actual danger. That all public institutions be required to transmit to the Board of Health the names and addresses of all persons suffering from pulmonary tuberculosis within seven days of the time when such persons first come under observation. That special inspectors be assigned to duty for the investigation of this disease, and whenever the department has become aware of the existence of families or premises where tuberculosis exists or has recently existed, it shall be the duty of these inspectors to visit such premises and deliver proper circulars and give suitable information to the persons residing there, and take such specific measures of disinfection as are required in each case. That the Board urge upon hospital authorities the importance of separation, so far as possible, of persons suffering from pulmonary tuberculosis from those affected with other diseases, and urge that proper wards be set apart for the exclusive treatment of this disease. That the Department of Charities and Correction be requested to set apart one of the hospitals under its charge, to be known as "The Consumptive Hospital," to be used for the exclusive treatment of this disease, and that, so far as practicable, all inmates of the institutions under its care suffering from tuberculosis be transferred to this hospital."

The report was referred to the Sanitary Committee of the Board for consideration.

The Death of Dr. Charles Warrington Earle, of Chicago, on November 19th, removes a physician well known in New York. He was a member of the staff of the Cook County Hospital and of that of the Wesley Hospital. He was Professor of Operative Obstetrics in the Post-graduate School, and had held a chair in the Woman's Medical College. He was a native of Vermont and in his forty-ninth year.

Dartmouth Medical College.—The graduating exercises of the Medical Departmant of Dartmouth College took place Tuesday evening, November 21st, a class of twenty-eight receiving degrees. The Medical Faculty have just passed the following vote: "That at the end of one full year of the study of medicine, and one course of lectures in this school, an examination will be required in descriptive anatomy, physiology, and chemistry. That at the end of two full years of the study of medicine in this school, an examination will be required in descriptive and regional anatomy, and further examinations in physiology and chemistry. The examinations so passed, if satisfactory, shall stand as final."

Raw Oysters and Typhoid.—Two persons in Berlin are reported to have died of typhoid fever, contracted by eating raw oysters. This statement is cabled from Europe. It will require some verification before it can be accepted. If typhoid bacilli get into oysters and grow there, it will be a very new habit, for they do not grow in brine, so far as has been known.

Prize of the American Neurological Association.—The American Neurological Association offers a prize of $200 for the best essay on any subject connected with Neurological Science. This competition is open to physicians who are legal residents of States in North and South America. Essays must be sent to the Secretary of the Association on or before the first day of May, 1894. Each essay shall be accompanied by a sealed envelope containing the name and address of the author, and bearing on the outside a motto, which shall also be inscribed upon the essay. Essays shall be type-written, in either the English or French languages, and with the

pages securely fastened. The Council of the Association reserves the right to reject any or all essays judged unworthy of the award. Each essay must exhibit original research, and none will be accepted that has previously been published. Græme M. Hammond, M.D., *Secretary*, 58 West Forty-fifth Street, New York City.

Harvard Football Casualties.—During the last four years a good many matches have been played at Cambridge and elsewhere by Harvard teams. The following are the casualties reported by surgical authority: Four fractures of the metacarpal bones, one fracture of the fibula, two dislocations of the elbow, one dislocation of the humerus, one probable fracture of a rib. Such injuries, when received by men in training, are recovered from in half the time necessary for recovery in other subjects.—*Boston Medical and Surgical Journal.*

A Medal Worth Having.—The gold medal which was presented to Professor Virchow, of Berlin, on the occasion of his seventieth birthday, recently, weighed nearly six pounds, and represented a value of about £350 in pure gold. Mme. Virchow received a silver, and each of the Professor's children a bronze, replica of the medal. The obverse shows the bust of the Professor, with the legend: "Rvdolphvs virchow. Pommeranvs Civis Berolinensis: Ætat LXX." On the reverse is an allegorical group representing the genius of investigation-winged, and carrying a flaming torch in the left hand, while with the right he lifts the veil of Isis. At the foot of the Isis column is a table with the representation of the Berlin Pathological Institute. In the background Science, on her lap an open volume, is seen contemplating a skull, while around her are other pathological emblems. The inscription on this side is "Omnis cellula a cellula."

The Late Dr. John C. Peters.—At a meeting of the New York Academy of Medicine, held November 2d, the following resolution was adopted:

Resolved, That there be placed upon the minutes of this meeting the following as a brief expression by the Academy of its appreciation of the character and professional merit of John Charles Peters, M.D., whose death has recently been announced. During a long life of professional activity he gave generously of money, time, and effort toward the promotion of science, the welfare of the profession and community, and the interests of the Academy. As an author, editor, and bibliophile he was eminent. He was foremost in the foundation of the New York Pathological Society, and contributed greatly to its successful development. His studies of Asiatic cholera are recognized as most important contributions to the knowledge of the profession both here and abroad, and his generous gift of the literature of this subject forms one of the most complete departments of our library. The incomplete list of nearly thirty titles of his works, given in the Index Catalogue of the Library of the Surgeon-General's Office, a large part of which relate to elaborate treatises, illustrates his activity as a writer and the comprehensive character of his knowledge. *The Medical Gazette*, the "Transactions of the Pathological Society and the Academy," are some of the evidences of his rare editorial ability. The numerous positions of honor and trust to which he was elected in the many organizations of which he was a member, evince the confidence of his associates and his remarkable executive skill. Few matters related to public sanitation failed to elicit his active support, and his communications through the secular press, whether anonymous or with his name were of great influence in directing public and legislative action. His intelligent supervision of our library and his influence with others, were the causes of much of its subsequent prosperity. His keen sense of personal dignity and probity made his example and precept respected by all who knew him, and his genial temper, kindly humor, and modest avoidance of anything that might be regarded as obtrusive, have endeared him to all his associates. The Academy was ever honored by his fellowship, and his friends were always the gainers in their relations with him.

Influenza is again showing itself in Russia and throughout Europe. The attacks are sudden and are attended with severe muscular pains and great prostration. Its general type is catarrhal, affecting the eyes and throat, and tending toward pneumonia. From present indications we may expect to hear from the disorder on this side of the Atlantic in a short time.

The Managers of the Utica Asylum and the State Commissioners in Lunacy.—The Managers of the Utica Asylum very properly protest against the wholesale insinuating charges of the Commission made, in a recent issue of the *New York Tribune*, against the bad management of the State Asylums. "We have," say the managers, "no fault to find with their successful efforts at blowing their own horn, so long as they do not do so at the expense of other men's reputations."

"Commissioner Reeves is quoted as saying that they have found State Hospital superintendents feeding numerous 'relatives, cousins, aunts, and nephews,' at tables supplied by the State. From these they have cut off maintenance. They 'have also declined to consent to a large number of people attached to the hospitals having horses and carriages—at least at the State's expense.' Failure to specify where, if anywhere, this is going on, serves to cast suspicion upon all, and it is an unmanly and undeserved insinuation. It is, moreover, casting suspicion upon all the managers of these several institutions, by leaving the door wide open to suspect that, knowing these abuses, they neglected to remedy them. If the Commissioners wish to stab anybody, it would be more manly to furnish a bill of particulars along with their complaint. The Managers of the Utica State Hospital respectfully protest."

Dr. MacDonald believes that patients should be compelled to work. At Utica the patients have always been asked to do what they could without risk to their health, though the officers have sought always to remember that insane persons are not convicts who can be forced to do a keeper's bidding.

Avoiding discussion of the merits of the Commission's anti tobacco crusade, the extravagant statement of the amount of money thus saved to the State can be easily refuted. From actual returns received from seven of the eight State hospitals, covering a year's consumption, it would appear that the expenditure for this item, for each hospital, averages $372, a total expenditure for the eight hospitals of $2,976, that is, less than thirty-five cents per year per capita, instead of a total expenditure of $15,000,

as alleged by Commissioner MacDonald. Moreover, this corrected estimate includes large quantities of tobacco for which the institutions were reimbursed by attendants and patients.

The protest thus concludes: "The whole tenor of the article of November 27th is that of a slur and insinuation upon managers and superintendents which a fair degree of self respect cannot permit to go unnoticed. The Commission is a centralization of power, and is putting into three men's hands more authority than was hitherto intrusted to the several boards of managers. If any manager, any superintendent, or any board of managers, has been recreant to this trust, it is proper to publish that fact, but it is neither dignified nor decent by generalization to indulge in wholesale defamation. The *Tribune*, we are sure, would be the last paper knowingly to grind any such axe."

Manhattan Hospital, New York.—Dr. H. C. Coe has been appointed Consulting Gynecologist to the Manhattan Hospital.

Dr. W. H. Holcombe, of New Orleans, died November 28th.

Mr. Gladstone's Physician.—Dr. William H. Broadbent has been chosen physician to Mr. Gladstone, in place of Sir Andrew Clark.

Complimentary Dinner to Professor R. W. Taylor, M.D.—A complimentary dinner was tendered on Wednesday evening, at Hotel Savoy, to Dr. R. W. Taylor by the attending staff of Charity Hospital, on his resignation as attending Surgeon of that institution to accept a similar position in Bellevue Hospital. The entire staff of Charity Hospital was present, with several invited guests. Dr. Thomas H. Burchard was the toast-master. Speeches were made by Drs. T. H. Burchard, R. W. Taylor, Commissioner H. H. Porter, Ex-Commissioner Thomas S. Brennan, Drs. George F. Shrady, Frank P. Foster, H. J. Garrigues, Thomas H. Allen, H. Goldthwaite, James E. Kelley, Mr. Massey (Caswell, Massey & Co.), Dr. Blanchard, of Fort Hamilton, and J. Blake White.

Dr. L. N. Luck, of Penn Yan, was stricken with apoplexy on Monday and died in a few hours. He was one of the prominent physicians of the Yates County Medical Society. He was fifty years of age.

Prize of the Alumni Association of the College of Physicians and Surgeons of New York.—The above prize, amounting to $500, will be awarded in June, 1894. It is open for competition to the alumni of the College, and is awarded for the best medical essay submitted upon any subject the writer may select. The conditions upon which the prize is awarded are as follows: If no one of the competing essays be deemed sufficiently meritorious, the prize is not awarded. An essay, in order to be held worthy of the prize, must contain the results of original investigations made by the writer. This prize is not awarded to any essay which is the work of more than one author, or which is at the same time submitted for another prize. Each competitor is required to send with his essay to the Prize Committee a statement that these requirements have been complied with. Competing essays must each be marked with a device or motto, and accompanied by a sealed envelope, similarly marked, containing the name and address of the author. Essays in competition for the prize to be awarded at commencement, 1894, must be sent to the Secretary of the Alumni Association on or before April 23, 1894.—T. M. Cheesman, M.D., Secretary Alumni Association, 46 East Twenty-ninth Street, New York.

The Late Dr. Phillippo.—Mail advices received last week report the death of the Hon. James Cecil Phillippo, in Jamaica, B. W. I. The late Dr. Phillippo was a son of the late Rev. Mr. Phillippo, a pioneer Baptist missionary to Spanish Town, Jamaica. The doctor's brother, who survives him, is Sir George Phillippo, Chief Justice of Hong Kong. Dr. Phillippo graduated as an M.D. at the University of Edinburgh, some forty years since. His lifetime was spent in Jamaica. He was President of the Medical Council of that island at the time of his death. Four times he was elected President of the Jamaica Branch of the British Medical Association. Previous to his recent election as President of the Legislative Council of Jamaica, he was a member of the Privy Council of the island. He had been a contributor to the medical press, including the MEDICAL RECORD. He was author of a book on the climate and springs of Jamaica. At the late Pan-American Medical Congress in Washington, he took a prominent part in reading two papers on "Jamaica, her Climate, Demography, etc." He was a firm believer in the island's future and perfect winter climate. Within a year, he had retired from active practice and had settled on a fine estate between Kingston and Constant Springs. He was a faithful and conscientious worker, and was greatly respected by all classes. He leaves a widow and several sons and daughters.

Mortality Report of New York State for October.—The reported mortality for October has decreased from a daily average of 311 to one of 290; in the corresponding month of last year about 100 more deaths occurred. The death-rate for cities and large villages was 18.50 per 1,000 population, and of the rural parts of the State about 15.50, that of the entire State being 18.00. The mortality in rural towns is much less than that of last month, and less than it was a year ago. The decrease applies equally to all parts of the State. From the principal zymotic diseases, except from diarrhœal diseases which caused 861 fewer deaths than in September, there has been an increase in mortality. The autumn increase in typhoid fever, which was low last month, is greater than usual, fifty more deaths occurring than last October; the increase has been in the Maritime and Western Districts. There were 185 more deaths from diphtheria than in September, and the increased prevalence over last year continues, being confined to the Southern and Central Districts; its prevalence is noted in Haverstraw, Tivoli, Sandy Hill, Moreau, and Ilion. There is a slight increase in scarlet fever, but it is less prevalent than last year. Measles and whooping-cough are decreasingly prevalent and cause but few deaths. Small-pox is diminishing in New York and vicinity; a case of varioloid developed in Geneva early in November, the origin of which has not been satisfactorily determined. The temperature for the month was a little above the average of 52°; killing frosts occurred about the 17th. The rainfall was generally deficient, except as reported from the New York station.

Society Reports.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Sixth Annual Meeting, Held in New Orleans, La., November 14, 15, and 16, 1893.

(Continued from p. 733.)

SECOND DAY, WEDNESDAY, NOVEMBER 15TH—AFTERNOON SESSION.

Wyeth's Bloodless Method in Amputation at the Hip, by DR. F. W. PARHAM, of New Orleans. He prefaced his own paper by reading some extracts from a paper by Dr. John A. Wyeth, read before the last meeting of the New York State Medical Association. He made use also of the statistics kindly furnished him by Dr. Wyeth. These statistics were as follows: Sarcoma, 17 cases, 2 deaths; 11.76 per cent. Inflammatory bone disease, 18 cases, 3 deaths; 16.6 per cent. Violence, 4 cases, 4 deaths; 100 per cent. Nerve injury, 1 case, no death. Total for disease, 36 cases, 5 deaths; 13.88 per cent. For injury, 4 cases, 4 deaths; 100 per cent. For both disease and injury, 40 cases, 9 deaths, or a total of 22.5 per cent. In this list is one case now published for the first time. Boy, aged three, sarcoma of thigh, recurrent, amputated by Wyeth's method by Dr. Parham, October 5, 1893, discharged, cured, October 24, 1893. These statistics show a mortality reduction for civil practice of at least one-half. Ashhurst's statistics gave 40.2 per cent. for disease, 82 4 per cent. for injury, or a total of 64.1 per cent. Leming gives gunshot wounds 98 per cent., disease, 42 per cent..

Dr. Parham referred to the various methods proposed for controlling hemorrhage at the hip and spoke of the various modifications of the Wyeth method. He specially urged that the outer pin should be placed higher, so that the disarticulation might be done before the tube was removed. He favored the suggestion of Thomas, that in placing the pins, the tube should be put around first at the proper place, and that then the pins should be put in at the lower border of the tube. He believed that the bone should be disarticulated entirely without sawing. In conclusion, the reader remarked, "I am inclined to agree with Murdoch that the method of Wyeth is the best yet devised."

DR. W. B. ROGERS, of Memphis, Tenn., read a paper entitled "Laparotomy in General Surgery—Report of Twenty cases."

Operative Procedures for Carcinomatous Tumors of the Breast.—This paper was read by DR. J. MCFADDEN GASTON, of Atlanta, Ga. He said a point of great moment, as to the extent of operative procedure, pertains to the leaving of any portion of the mammary gland, when only partially implicated in the carcinomatous growth. The æsthetic element should never enter into the decision of such a vital question as the arrest of carcinoma, and whenever a breast is the seat of a malignant tumor, whether wholly or partially involved, there should be no hesitation about removing the entire glandular structure. If a part of the mammary gland only seems to be involved and it is evident the knife can be carried outside of the neoplasm into the apparently sound tissues of the breast, there is every reason to believe that if any portion of the gland is left it may become the seat of disease, and that recurrence will most likely follow the operation. On the other hand, an entire ablation offers better prospects of success.

The relative advantages of the knife and cauteries in the management of carcinoma depend very much upon the progress of the disease. In the incipiency of the local trouble there can be no doubt in regard to the excision being preferable to cauterization, but after full development of a tumor with a tendency to degeneration and breaking down of its structure the resort to escharotics has its advantages in extending to the remote ramifications of the disease. It is a prevalent impression that certain caustic applications attack diseased structure without affecting the sound tissues, and that the so-called roots of a cancer are thus destroyed. There seems to be some just foundation for this belief in regard to applications of arsenic, but the destructive effect of caustic potash in the form of Vienna paste extends to every vital structure with which it comes in contact, and the same holds in reference to the plaster of sulphuric acid and charcoal as an escharotic.

Dr. Gaston said the treatment of carcinomatous tumors of the breast with caustics has been tested fully by Bougard, of Belgium. His paste contains chloride of zinc, arsenic, cinnabar, and corrosive sublimate. Of one hundred and sixty cases, sixty-two, or nearly forty per cent., were free from recurrences three years after treatment.

The Diagnosis of Some Abdominal Tumors Supposed to be Ovarian, by DR. JAMES A. GOGGANS, of Alexander City, Ala. Dr. Goggans said the first requisite of the abdominal or pelvic surgeon is to acquire the ability to make a diagnosis. Text-books lead one to believe that this was quite an easy thing to do, but his experience had convinced him to the contrary. He then reported a few cases which had come under his observation which served to illustrate the fact that the diagnosis of many cases is often difficult, and in some cases quite impossible.

Does Gonorrhœa in the Female Invariably Prevent Conception?—DR. JOHN T. WILSON, of Sherman, Tex., read a paper on this subject. He said it has long been known that gonorrhœa in the female was sometimes attended with complications that proved troublesome and of serious import. Authors had for many years been describing endometritis, metritis, inflammations of the tubes, ovaries, and peritoneum produced by an ascending specific vaginitis, these structures being invaded by the poison, slowly creeping up through the cervix, involving first the mucous membranes in its tract and extending by continuity of structure to the deeper tissues. The more serious results, however, were not appreciated, nor so well understood until within recent years, when laparotomy became so common an operation, and the pathology of the more important sequelæ were studied from the specimens themselves. According to the experience of our best authorities it is so difficult to positively differentiate between gonorrhœal and severe simple vaginitis without a clear and authentic history, it being attended with the same symptoms and the properties of also infecting the male, that it is not altogether an easy task to say when ovarian, tubal, and uterine troubles, even with the presence of the Neisser gonococcus, have a specific origin, especially as simple vaginitis will sometimes produce them all. Dr. Wilson had observed quite a number of women who were the victims of gonorrhœal infection, many of them innocently so, having contracted it from their husbands, and believed it to be an ordinary leucorrhœa; many of those whose history he was enabled to follow afterward bore children for many years, were apparently healthy and gave no evidence of the usual complications.

Dr. Wilson then reported cases illustrative of some of these conditions and results. That gonorrhœa does frequently prevent conception is probably well established; but he does not think it is by any means the universal rule, clinical illustrations are too many to the contrary. If Nœggerath's statements are literally true, sterile women and fruitless marriages would be far more common, and the increase in the race would be greatly lessened, for there are a surprisingly large percentage of men, judging from his experience, who, if they confessed the truth, have suffered at some time in their lives with gonorrhœa.

Some Remarks on the Practical Treatment of Hepatic Abscess, by DR. JAMES E. THOMPSON, of Galveston, Tex. The author confined himself to a few practical remarks on the diagnosis and treatment of hepatic abscess and reported two interesting cases. He mentioned a few points on the treatment of the cavity after the contents had been successfully removed. It is often exceedingly

difficult to obtain free drainage even when large tubes are employed. In some cases even swabbing the walls of the cavity is ineffectual and these cases are practically hopeless, owing perhaps to inherent tissue weakness. The author tried curretting in one of his cases, and although he removed, as he thought, all necrotic tissue, still in a few days the cavity was as bad as before. Continuous irrigation often affords a means of efficient removal, but the tubes have an aggravating habit of becoming blocked, necessitating frequent changing and cleaning. Irrigation with a solution of sulphate of quinine—1 to 1000—was in one of his cases remarkably successful, and although the improvement may have been a coincidence and not a *post hoc ergo propter hoc*, he thinks that in cases of amœbic dysentery, at least, it deserves a fair trial.

Election of Officers.—The following officers were elected for the ensuing year: *President*, Dr. Cornelius Kollock, of Cheraw, S. C.; *First Vice-president*, Dr. A. B. Miles, of New Orleans, La.; *Second Vice-president*, Dr. J. B. S. Holmes, of Rome, Ga.; *Secretary*, Dr. W. E. B. Davis, of Birmingham, Ala.; *Treasurer*, Dr. H. P. Cochrane, of Franklin, Tenn.

After introducing and adopting resolutions of thanks, the association adjourned to meet in the city of Charleston, S. C., third Tuesday in November, 1894.

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, November 29, 1893.

D. B. St. John Roosa, M.D., President, in the Chair.

Before introducing the orator of the evening the President made some remarks to the audience, composed largely of the laity, upon the work which had been accomplished by the Academy in the public interest.

Modern Experimental Medicine.—Dr. William H. Thompson read the anniversary address. No physician who had lived long enough in the practice of his profession to compare the state of medicine as it was twenty-five years ago with the same at the present day could fail to recognize the fact that virtually a revolution had characterized the interval. This change was not simply from increase of knowledge, great as that had been, but more from a change of methods in the pursuit of knowledge, with the result of altering the whole domain of medicine to an extent which only the term revolution could fully express. It happened, however, that, as in other revolutions, many who lived in their epoch and who even took part in them, yet failed to appreciate at the time their full significance, and therefore remained long unaware of the essential difference which separated the new order of things from the old. With a view to illustrating the import of the new era which was now fully upon us, he would briefly refer to the chief methods of inquiry and investigation which had been pursued by the medical profession a quarter of a century ago and compare them with the experimental medicine of to-day.

First of all in the estimation of the profession at that time came clinical medicine, or the knowledge which could be gained of disease at the bedside of the sick. To be able to investigate disease to good purpose when face to face with it required no small preparation on the part of the physician. For that preparation anatomy was the first lesson, and no complaint could be made with this essential. But as soon as the microscope was discovered workers everywhere began to study the ultimate anatomy of the body with most fruitful results, thereby doubling the amount of knowledge which it had been necessary for one to acquire who wished to enter the profession of medicine. With this advance of knowledge in the structure of the body, it was to be expected that there would be like advances in other departments, as physiology, physiological chemistry, pathological anatomy, etc., and it had come to pass. Why were all these helps not sufficient to advance knowledge until every serious problem in medicine had been solved? The answer was that by none thus far mentioned could the vital question of etiology, or the causation of disease, be at all satisfactorily demonstrated. There was absent one great requisite in all scientific demonstration, namely, experiment. In no scientifically conducted investigation was observation alone sufficient. Observed facts never could be satisfactorily interpreted except by experimental tests. The insufficiency of clinical medicine and pathological anatomy to interpret disease was well shown by the history of pulmonary consumption. All was theory until Koch, by tests peculiar to work in the bacteriological laboratory, demonstrated its causation in tubercle bacilli. Erroneous interpretations springing from this field tended to correct themselves. Mistaken experiments, unlike mistaken doctrines, were always short-lived, and he commended this fact to all those who were disposed to dwell upon the contradictory reports in experimental investigation if certainty could never be thus reached. The experimental method did not get at its hid treasures by a lucky find, nor did the final test end with the work of a single investigator. No claim which was not based on truth could survive the ordeal to which it was subjected at the hands and methods of the many workers in laboratories. The history of the discovery of the tubercle bacillus also served as an illustration of what immense benefit to the human race was a knowledge of the causation of disease as revealed through experimental medicine. Tuberculosis had been the cause of one-fourth of all deaths, yet it was now known to be a preventable disease which could be greatly limited in extent by even the simplest of methods.

Dr. Thompson then pictured the enormous amount of work which was being done by the profession in the different departments of experimental medicine. There was the worker in the physiological laboratory, the worker in pathology, a department which Horsley with much warmth had insisted should be distinguished from that of morbid anatomy, and which had, during its recent cultivation, so greatly advanced our knowledge of myxœdema, and promised much more; then there was the worker in the bacteriological laboratory; also the worker in physiological chemistry, a most complex and difficult department, which, however, was especially essential to a knowledge of ultimate etiology. Brief reference was made to the practical additions to our knowledge growing out of experimental medicine in different parts of the world. The laboratories in the United States, which had been founded by private munificence, had been of recent date, but their reports had already come to be quoted by scientists abroad, and the work which they had accomplished had been original as well as corroborative, and also of great practical utility. England had long been behind the Continent in experimental medicine, owing to hostile legislation, but this had been so far remedied that she was no longer under the necessity of sending her students abroad to study in the laboratories of Berlin and elsewhere.

The public should be taught that all this work was being carried on in order that modern medicine might equip itself for contending against disease, and thereby for blessing the entire world. In view of this fact he could but refer with sorrow to the mistaken efforts of a few who sought hostile legislation against experimental medicine on the basis of cruelty to animals. One part of the animal world lived upon the other, and suffering and death were inseparable from existence. The question of whether inflicting pain constituted cruelty rested solely upon the objective purpose. Only unnecessary suffering was cruelty and should be condemned.

The medical profession was the only universal brotherhood. Think of lawyers, or legislators, or even ministers of the various religions, councilling with one another with the one common object of advancing the welfare of the whole of mankind.

Dr. Thompson thought that our government might well expend some of the money which it raised by taxation in aiding laboratories.

At the conclusion of the address the President invited those who were strangers at the Academy to inspect the library and various meeting-rooms.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, October 26, 1893.

H. J. BOLDT, M.D., CHAIRMAN.

Combined Cranioclast, Embryotome, and Cephalotribe.—DR. J. CLIFTON EDGAR presented the instrument, of French make, which he said had found much favor in Europe. He could not speak of its value from practical experience.

The Toxæmia of Pregnancy.—DR. EDWARD P. DAVIS, of Philadelphia, in presenting a paper on this subject said that he meant by toxæmia of pregnancy the condition occurring in the pregnant woman where toxic material was present in the body in excess. There could be no nutrition without waste, which was greater owing to the dual existence in pregnancy, and as the excretion of this waste material took place largely through the kidneys it was to these organs that attention had been chiefly and almost solely directed for some years. Increasing knowledge of pathology had shown that the kidneys were only partially at fault. The usual metabolic process explained a portion of the cases, while in some others the signs pointed to additional intoxication with bacterial products.

The paper dealt more especially with methods which they had found useful in the diagnosis of toxæmia, with treatment and with clinical cases. Details in methods of examining the urine were not mentioned, but the value of microscopical examination, it was stated, could scarcely be overestimated. The specific gravity and the amount of urea were important in judging of actual or threatened toxæmia. The presence or absence of albumin alone was not so significant. Where the urea had fallen below 1.5 per cent. they had found that stimulation of the patient's excretory organs caused improvement of those symptoms which pointed to milder degrees of toxæmia, supposing graver symptoms had not yet developed. The urea was not regarded as the poison itself, but as approximatively expressive of the solid constituents of the urine. In fifty-four cases the average per cent. of urea during the pregnant state had been found to be 1.8. It had been noticed that in the majority of cases the amount of urea had increased after delivery. On the other hand, marked diminution occurred only in cases either having or being threatened by eclampsia or manifesting symptoms of marked toxæmia.

Some of the symptoms of toxæmia which called for treatment were diminution of the solid constituents of the urine, reduced appetite, gastric distress, headache, clammy skin—in some instances a dry skin—lassitude, and nervous disturbance. They had not regarded the presence or absence of serous albumin alone as indicating toxæmia. In one-half the cases sugar was present at irregular intervals during the pregnant and puerperal state. The presence of glucose or lactose bore no direct relation, as far as they could determine, to the toxic condition of the patient. Of the fifty cases which formed the basis of the paper, fully one-third had, at some time during their residence in the Maternity, developed symptoms of toxæmia which required eliminative treatment. It was possible for a condition of marked toxæmia to be present in which examination of the urine failed to reveal either casts, albumin, or marked deficiency of urea.

The treatment was eliminative, through the kidneys, liver, intestines, skin, and lungs. Give milk and other food, if necessary, to keep up the strength; pure water, but not in excess, as it was possible to seriously embarrass the kidneys by a sudden increase of the fluid taken. He had no doubt of the advantage of the occasional use of calomel and soda, followed by a purgative to produce free and liquid stools; potassa salts were to be avoided. Colocynth was efficient in these cases. Wear woollen next the skin summer and winter; hot baths, hot sheets, gentle massage, including limbs and back, but avoiding the abdomen; fresh air; induce labor if necessary.

Toxæmia showed itself especially through disturbance of the nervous system, but relief was to be brought about in the manner indicated and not through sedatives. He was opposed to sedatives and narcotics if improvement could be brought about by elimination. Where an anæsthetic was required he preferred chloroform. Recent literature contained striking evidence in favor of terminating pregnancy by dilating the uterus and extracting the fœtus. The author thought it was a mistake to administer drugs which were depressants. Stimulants might be employed when indicated.

DR. W. T. LUSK thought that many of the symptoms described in the paper as belonging to the toxæmia of pregnancy also occurred in the non-pregnant state, and the eliminative treatment was of value in both classes of cases. But it was to be regretted that most cases which he had seen in pregnant women were those in which the kidneys were affected, convulsions threatened, calling for prompt measures. There was a time in New York when he had stood almost alone in favor of emptying the uterus, and he had been led to this step in opposition to common practice because without it he had been able to do little more than stand by and watch the patient die. He wished we had more positive evidence of what was the cause of the symptoms, for the theories which had been advanced had been abandoned one after the other with further knowledge of pathology.

DR. VON RAMDOHR referred to some questions in etiology and said that whatever the correct theory of the eclamptic attacks might be, clinical experience taught that they were more likely to occur in primipara, where the placental surface was extensive, as in twin pregnancies, and in certain conditions of nervous irritability. He thought that the quicker the woman was delivered the better; treatment by chloroform, blood-letting, etc., was of secondary consideration. Extraction of some blood, however, would seem of some value practically and theoretically, and was not an objection in Dührsen's incisions where the latter were called for to effect rapid delivery. He had seen very severe cases, which would account for his high mortality, about fifty per cent.

Recommends Accouchement Forcé.—DR. EGBERT H. GRANDIN thought the paper was a very valuable one, especially in that it called attention to symptoms of toxæmia during pregnancy, the gravity and real nature of which were apt to be overlooked. He mentioned one case of convulsions in which the woman died in coma after labor. The urine had contained no albumin, no casts; specific gravity was normal. He had seen a number of somewhat similar cases in hospital practice. He was glad to learn that rapid emptying of the uterus where the symptoms were severe or threatening was coming to be the practice in Philadelphia and New York, for when he had resuscitated accouchement forcé a few years ago, in certain urgent conditions, his views had met with considerable opposition.

DR. EDGAR said the fact that a woman might have eclampsia when the urine was seemingly normal, had been forcibly impressed upon him by two fatal cases seen last spring. Regarding treatment, he stood with those who favored immediate emptying of the uterus.

DR. ROBERT A. MURRAY thought that, whatever theory might be the correct one regarding eclampsia, there was some form of toxæmia, and treatment based on that view gave the best results. In cases with milder symptoms elimination should be tried, but he believed with Drs. Grandin and Edgar that it was useless to temporize with severe cases; that the uterus should be emptied at once. The convulsions might be controlled by chloroform during the emptying of the uterus, but he was opposed to using hydrate of chloral, believing that it had sometimes brought about a fatal result through its depressing effects upon the heart. He would dilate the cervix with the finger. The loss of some blood after labor was of benefit rather than harmful.

Dr. Mary Putnam-Jacobi thought the paper was in line with Bouchard's recent work on auto intoxication, the main features of which she outlined, and showed the harmony between them and the clinical facts of toxæmia or eclampsia in the pregnant woman.

Dr. E. A. Ayers thought many facts pointed to pressure interference with the pelvic circulation as the chief cause of actual or threatened convulsions during pregnancy, and treatment based on that view gave the best results. The patients were often primipara, the abdominal walls were tense, there was usually head presentation. He performed external version, caused the bowels to act, in one case kept the patient on her side. This treatment had caused œdema of the legs to disappear, cleared up albumin from the urine, and improved the patient's general symptoms. Nitro-glycerine had also been of value, and was not a depressant. A case was mentioned in which the one-hundredth of a grain every three hours caused marked reduction of the albumin and casts.

The After-history.—Dr. Van Santvord thought the after-history of these patients should be obtained, and it could be best done by the general practitioner. He referred to two cases in which the urinary symptoms showed a chronic nephritis after a year or two.

Dr. W. R. Pryor thought there was strong similarity between the cases occurring during pregnancy and others, especially those showing evidence of Bright's disease, and the treatment should be carried out with a view to restoring a balance between tissue waste and elimination. In addition, empty the uterus.

Dr. Davis closed the discussion.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

Semi-Annual Meeting, held at Annapolis, Md., November 22 and 23, 1893.

Dr. George H. Rohé, President, in the Chair.

First Day, Wednesday, November 22d.

Address of Welcome.—This was delivered by Dr. Abram Claude, of Annapolis.

President's Address.—This was delivered by Dr. George H. Rohé, who thanked Dr. Claude and the profession of Annapolis and of Anne Arundel County for the hospitable reception, and then referred to the great prosperity of the society and suggested some very important and practical changes which were afterward considered and acted on at the business meeting.

A Case of Laminectomy; Operation Eleven Months after Injury to the Spine.—This was a paper by Dr. W. B. Platt, of Baltimore. Hippocrates, who was such a voluminous writer, does not mention this operation. Paul of Ægina was the first writer to notice this operation nearly twelve hundred years ago. It was generally fatal in its early days because it was not done with antiseptic precautions. Henry Klein, in 1814, was probably the first surgeon to do this operation. The patient died and the surgeon was censured. Many others after him reported fatal cases. It makes a difference whether the operation is done at once, as soon as the accident has happened, or some time after the injury. Fractured laminæ are generally present with fractured spine. The laminæ become displaced and press on the cord. The operation should never be done to relieve the paralysis of Pott's disease until all other means have been tried and the patient is growing worse. Statistics show that over eighty per cent. of such cases recover without operation. In perfectly hopeless cases the operation is advised. His patient had first slipped on the stairs and two weeks later he fell from a car and one week after that he suddenly complained of extreme pain in the back and went to bed. There was found a curvature of the spine at the point of pain and below this there was complete paraplegia with loss of sensation. Bed-sores appeared, but there was no discharge of pus from any place except from the bed-sores. The operation had been done about two weeks ago, and two parallel incisions were made to the inner side of the transverse processes and were joined by a transverse incision. The hemorrhage was checked by pressure and the laminæ of the fifth, sixth, and seventh vertebræ were cut off. The flap was turned down for four inches and the dura was exposed; it looked healthy. The flap was replaced and no arteries were tied, and the operation lasted one hour and twenty minutes. There was copious venous hemorrhage. The patient is at present writing better, but still has skin anæsthesia; there is no improvement in motion. In such operations the improvement in sensation comes first. The patient can lie on either side without fatigue and no longer has night sweats as he had at first, although the most careful examination failed to show at any time any signs of tuberculosis of the lungs. Dr. Platt also showed a specimen from a cadaver to illustrate his paper.

Dr. R. Winslow had been considering for some time the propriety of doing this operation and he related several appropriate cases from his own practice. In one case there was complete paralysis below the eighth nerve and in another there was paralysis from the clavicles down and in neither case did an operation do any good and he does not put much belief in laminectomy.

Dr. George J. Preston in the last few years had seen several such cases and in some he had recommended an operation, with bad results. He does not know which cases should be operated on. If the cord is cut entirely across, an operation will do no good. The spinal cord in human beings will not unite to any extent as it does in dogs after section and as the nerves do. If an operation is to be done it should be done at once, for if we wait until secondary degeneration has set in it will do little good. The operation should be done a few days after shock, hemorrhage, and effusion have passed away; then operate as we do in other cases. There is not so much injury done by the pieces of bone as by the effusion and the tissue formation around the cord.

Dr. Platt in closing said that the prognosis of the injury and of the operation depended on what part of the spinal column was injured. In general, the nearer the head the less chance there was of success. We should always consider laminectomy as we do trephining of the skull; in fact laminectomy is nothing more than trephining and the mere operation is not dangerous, it is only the injury. If the body of the vertebræ is fractured we can expect little. Hippocrates gives good advice on this point.

Tumors of the Superior Maxilla.—This was the subject of a paper by Dr. J. H. Branham. He gave an extended account of treatment and showed specimens illustrating the subject.

Amputations.—This was the title of a paper by Dr. Randolph Winslow. He said that since the introduction of rapid transit in our large cities, surgery of all kinds had increased and particularly was there a greater necessity for amputations than before. He considered the condition of the blood supply to the injured parts the most important condition for a successful operation. He then related several cases and spoke of tetanus as one complication.

Dr. J. M. T. Finney said he would like to emphasize a remark of his late instructor in surgery at Harvard, who said that any fool could amputate a leg but it took a surgeon to save it. He thinks there are other methods than amputation, and Thiersch's skin grafting is one. There seems to be a tendency to save limbs entirely useless for a future amputation. This may be a good thing, because a stump made from a later amputation in which the parts are in good condition is a much better stump than one made at once. All these things must be taken into consideration. There is no question so important as whether we should amputate the limb or not. Another point Dr. Winslow had made was that of the time of operation. He had recommended waiting until reaction from shock had set in. The majority of cases are much better oper-

ated on at once unless the shock is very severe. Dr. Winslow referred also to the question of tetanus; it does occur in a certain number of cases, but the bacillus tetani in anaërobic and grows best where air does not have access to it. In a bullet wound or punctured wound from a toy pistol or rusty nail there is danger of tetanus because as most dirt earth so often contains this bacillus it is carried in with the object wounding and stays in the wound. This can be guarded against by laying such a wound open freely, the more freely the better.

Dr. Winslow was called away at this time and made no reply to these remarks.

A Study of the Effects of Tobacco on the Throat and Nose.—This was the subject of a paper by Dr. W. T. Cathell. He divided smokers into three classes, those that tobacco did not injure at all, those whom it injured to a slight degree, and those on whom it had a poisonous effect. The oil and nicotine were the poisonous principles. He condemned especially the short pipe and the stump. He thought that the pipe might be the exciting cause of cancer of the tongue and tobacco of polypi. He painted a very sad and painful picture of the results of using the weed.

Dr. C. Birnie, of Taneytown, Md., did not think that physicians could dwell too much on the harm which tobacco does to growing boys, but the rest of Dr. Cathell's indictment was entirely too severe, and for his part he did not believe that tobacco had ever caused cancer or polypi. A very common remedy among people in the country is tobacco. The wet tobacco leaves or a wet chew from a friendly mouth is put on a fresh wound and never removed until it heals, and recovery is perfect. He had seen this often and while he does not advocate it, the wound gets well, whether the tobacco does it or not. At any rate it does not prevent it from healing. It may be a case of post hoc. Chronic conditions of the throat and nose are just as common among the women as among the men, and few women in the country use tobacco as men do.

Dr. William H. Welch agreed with what Dr. Birnie said, and was glad to hear his remarks after the gloomy picture painted by Dr. Cathell. There is very little evidence to show that tobacco produces organic or malignant disease. The mechanical action of the pipe may cause an epitheliomatous papilloma but not a cancer. He was much interested in Dr. Birnie's remarks on the treatment of wounds by tobacco. It had been shown in his laboratory at the Hopkins that the action of tobacco smoke on bacteria as the smoke was drawn through the culture tube, was inhibitory. There had also been a physician in his laboratory who had always the diplococcus pneumoniæ in his mouth and from whom the other workers used to get it for cultures. The physician began to chew tobacco and no more cultures could be made from his mouth secretions.

Dr. Abram Claude said that he had been practising fifty-five years and had rarely been without a chew of tobacco in his mouth for most of that time; he is now seventy-four years old. He did not advocate its use in the young, but some it injures and others it does not, never mind how much they use it. His father had chewed it for many years, and his friend, Dr. Ridout, lived to the age of ninety a constant chewer. Dr. Cathell had brought forward no proofs of his statements of the injurious effects of tobacco, nor had he ever made any post mortem examinations of the fatal cases.

Dr. Cathell in closing said that the cases of Dr. Claude belonged to his first class who were not injured by tobacco. He had not said that smoking and chewing could cause cancer or polypi but that they might be the exciting causes of these troubles.

Some Facts and Suggestions Concerning the Care of the Insane in Maryland.—This was the subject of a paper by Dr. George J. Preston, in which he reviewed the history of what had been done in this State for the care and the treatment of the insane, and spoke of what the faculty had done in this connection. The State is in some sense obliged to take care of its insane and provide better accommodations for them than for the pauper class. The methods should be both scientific and humane. It would be more economical for the State to take intelligent care of its insane, for more of the favorable cases would be permanently cured and thus cease to be a burden on the State. The State should assume entire control of all public insane in her borders; the acute and chronic cases should be treated in separate institutions. Also there should be at some central point or in the large cities, as at Baltimore, a detention hospital or ward where those becoming suddenly insane, the cranks of all kinds, could be confined until their cases could be studied and a proper disposition of them made.

Dr. Henry M. Hurd said that the insane should have State care; county care is only an excuse to economize. If the State deprives a man of his liberty, the State should take care of him as well as possible. He does not believe in dividing acute and chronic cases. He does not believe that any man knows who is curable and who incurable. We should have a detention hospital for the temporary care of the insane and study these cases and know where they belong.

Drs. E. N. Brush, R. F. Cundry, S. J. Fort, and C. Birnie spoke of the manner of obtaining proper legislation on this point and its great importance.

Dr. William H. Welch said the paper read was a most excellent one. He thought whatever was done the insane should be used for medical education, and the general practitioner should know something of insanity. We should take no step that would throw the material away from Baltimore and keep it from being used in teaching. The provision should not exclude the possibility of using the insane for clinical material.

Dr. B. D. Evans, of Morris Plains, N. J., also spoke in the same general direction.

Advancement in the Care of the Insane in Maryland During the Past Eight Years; Insanity in the Colored Race.—This was a paper by Dr. William Lee, Secretary of the Maryland Lunacy Commission. As a result of these papers and discussions resolutions were passed and a committee of twenty-five was appointed to bring the matter in proper shape before the next legislature.

Dr. Thomas H. Brayshaw, of Glen Burnie, Md., read a paper entitled "Is Psychic Research a Benefit to Mankind?"

Psychical Epilepsy.—This was by Dr. S. J. Fort. In the discussion Dr. H. M. Hurd did not accept his nomenclature, nor did he agree with him as to his conclusions; it is an unfortunate name for those not having epilepsy.

Dr. E. N. Brush did not like the name moral imbecility. Children may be educated too much and rest may help them. We may educate our imbecile into a criminal as he gets older.

Second Day, Thursday, November 23d.

Artificial Vesico-vaginal Fistula for Examination and Treatment of Ureteral Diseases.—This was the subject of a paper by Dr. B. B. Browne.

Dr. H. A. Kelly remarked on the value of this paper, and said that where formerly he relied on touch and feel to explore the bladder and even catheterize the ureters, he had now taken up the plan of using the head mirror and throwing so much light into the bladder through the speculum that every part was as light as when we examined the pharynx, and he could see with distinctness the opening of the ureters. He showed a series of photographs demonstrating how easy it was to use the headlight for this object and how important it was for the general practitioner to get into the habit of using the newest methods of making examinations.

Sterility Due to Tubal and Ovarian Disease.—This was a paper by Dr. T. A. Ashby.

Dr. J. E. Michael was much pleased with the paper of Dr. Ashby and thought it emphasized the tendency of these times to save rather than destroy the organs of

woman. This will be of great service in increasing the population. The theory of the fimbriated extremity grasping the ovary during the ovulation was, he believed, an exploded one, although from the nature of things this was not certain. He thought that ovulation was rather by a current set up in the ciliated epithelium of the tube, and disease of the tube interfered with the ciliated epithelium and ovulation did not take place. Ovulation and menstruation were not synchronous, ovulation goes on before menstruation begins at all. Many pregnancies occur before the establishment of menstruation.

Dr. Charles P. Noble, of Philadelphia, said it was time to recognize that sterility depends more on the ovary and tube than on the vagina and uterus, and if the uterus were more often let alone it would be so much the better. Abdominal surgery is much safer than it was, and this is the secret of many operations; it is not that the operator is more anxious, but he can dare to do it. The combined work of Price, Dudley, and Martin had been put down at two pregnancies as the result of all their operations, and it was an open question whether these two pregnancies had anything to do with the operations. He had little faith that diseased tubes could ever amount to anything. We can save an ovary that is partly diseased. Some adhesions disappear of themselves and these may be of puerperal peritonitis. It was well to use palliative measures of treatment in these cases.

Dr. H. A. Kelly said that Dr. Ashby had struck the right key-note, or to be more classical "rem acu tetigisti." It is very important that the general practitioner should know how to approach a case of sterility. No man should pronounce a woman sterile until he had examined the husband. Examine the semen. Impermeability of the os uteri is often the cause of sterility and simple dilatation will effect a cure. In some cases he has found small tumors pressing on the tube and presenting an obstacle to the passage of the ovum.

Dr. Ashby, in closing, said that the question of the physiology of menstruation was a speculative one in the human being, but we can learn much from comparative anatomy. He does not believe in opening the abdomen by way of experiment.

Dr. H. A. Kelly reported thirty-nine cases of removal of the uterus, some by the vagina, some by the abdomen, with one death, which was not due to the operation but to septic catgut. The earlier work had been done by the clamp method, drawing out the tumor, putting on the clamp, and leaving it there until the wound had healed. Then there were the combined extra- and intraperitoneal methods. The abdomen was opened, tumor lifted out, vessels tied, stump cauterized to prevent sepsis, and then fastened to the lower angle of the wound. He thought that the unilobular tumors were more common in women who had borne children. He operated for good reasons only. His present method was first to make an incision, then put on ligatures to stop the hemorrhage as he went on. He had noticed that the tumor seemed to take the shape of the pelvic canal when it was situated there. There were only four large arterial trunks feeding the tumor and two were reached at once. The broad ligament was pulled aside by the fingers. He took great care not to get the contents of the uterus and cervix on the stump; cleaned out the abdomen, although it should never have a chance to be otherwise than clean; stopped venous oozing, cut off ligatures, and dropped the stump back into the abdomen, turning the pedicle upside down, so that the bladder is exposed to view.

Dr. Charles P. Noble, of Philadelphia, said that the subject of the operation on fibroid tumors was of great interest just now to gynecologists. Formerly it was thought that they were innocent things that were never cured and should be left alone, as it was supposed that they disappeared at the menopause or did no harm. This teaching is undergoing revision and it no longer holds. The menopause is often put off in such women to the fiftieth or fifty-fifth year, and it is very discouraging to tell a young woman that she must drag on for thirty years or more with no help and perhaps no improvement at the end of that time. Many do not cease to give trouble even at the menopause. The first five cases he had operated on were of this kind. These patients are great sufferers. He thought that a tumor that weighed five pounds could be called a large one; a two-pound tumor in the pelvis will fill it and he had never seen a fibroid that weighed more than eight pounds. In all the operations he had done where the stump was left in the angle of the wound hernia had resulted. The method of operating has been developed by many surgeons. He did not advocate using the ligatures in the cervix and thought it was unnecessary to put on ligatures in the vagina, and he does not think there is any use in cupping out the cervix. He did not think that we removed enough fibroids. Why should we leave a fibroid in to get big? It is safe surgery to remove it when it is small, and we should do it.

Dr. J. E. Michael thought that gynecological operations were like other surgical operations, and advanced and changed in the same way.

Dr. H. A. Kelly closed by saying that he had once been asked in court as an expert witness, what a large tumor was, and he replied that a tumor was large when it exerted pressure on the surrounding parts. A tumor that was large in the pelvis is not necessarily large in the abdomen.

Gynecological Operations Outside of Hospitals.—This was the title of a paper by Dr. Hunter Robb.

Dr. W. S. Gardner also thought that operations could be done outside of hospitals as well as in, if care were taken. In cases where there is a large collection of pus and where much irrigation is needed, it is not advisable to operate at home. He does not believe that wounds become infected from the atmosphere. He does not think it is necessary to take the sterilizer to the house, as sterilization can be done at home before starting, and if the instruments, sponges, etc., be kept in the cotton in which they were sterilized, they will keep clean. It is just as well to have plenty of sterilized water but it is rarely well to use it.

Dr. J. Fridenwald read a paper entitled "Atony of the Stomach."

Subcutaneous Infusion of a Nutritive Salt Solution in Cases of Refusal or Inability to Take Food.—This was the subject of a paper by Dr. Milton D. Norris, and was the result of his experience in feeding cases at Spring Grove Asylum.

The paper was discussed by Drs. Brush, Evans, Gundry, Branham, Rohé, and Fulton.

Water Supply, Isolation, and Disinfection in Country Districts.—This was the paper by Dr. C. Birnie, of Taneytown, Md., in which he showed the carelessness of country people in respect to their drinking water and disposal of their sewage and the filthy way they arranged their water closets.

Dr. George H. Rohé said if he dared to make a comparison he would say that this was the best paper of the session.

Dr. Canfield said he thought the paper was especially to be commended for the practical and simple nature of the suggestions made; he thought this was the age of preventive medicine and we needed just such papers as this.

The paper was further discussed by Drs. Hines, Evans, and Brush.

"Hemorrhagic Septicæmia" was the subject of a paper by Dr. W. T. Howard, Jr. It was discussed by Dr. J. Friedenwald.

An apparatus for the estimation of urea was exhibited by Dr. John S. Fulton, of Saulsbury, Md., and was discussed by Drs. J. Friedenwald, Canfield, and Fulton.

"Obstruction of the Bowel" was by Dr. Edward Anderson, of Rockville, Md.

Gleanings from Country Practice was a paper by Dr. Frederick J. Dunning, of Easton, Md., and contained a report of a case of supposed yellow fever and

his first abdominal section. It was discussed by Drs. Canfield, J. Friedenwald, and Fulton.

At a business meeting of the Society Dr. William H. Welch brought up the report of the National Quarantine Committee of the New York Academy of Medicine on a Bill to Establish a Bureau of Public Health within the Treasury Department of the United States, and offered a resolution, which was unanimously carried, to appoint a committee of nine to further the passage of this bill. This bill is very important and has been prepared with great care and with due regard to the National Government and States' rights. The object of the committee is to further the passage of the bill and to co-operate with the committee of the New York Academy of Medicine.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 11, 1893.

T. Mitchell Prudden, M.D., in the Chair.

Report of the Microscopical Committee.—The Microscopical Committee reported that an examination of the specimen of bone from a knee-joint, presented by Dr. T. H. Manley, on May 24, 1893, failed to show any evidence of tubercular inflammation, but demonstrated the presence of a periostitis and a slightly marked osteitis, whose etiology could not be determined.

Malposition of the Fallopian Tubes.—Dr. George P. Biggs presented two Fallopian tubes which had been found situated behind the uterus, and firmly united by their fimbriated extremities. There was a free communication between the tubes. The specimen was removed from a woman, twenty-nine years of age, who stated that shortly after a miscarriage, six years before, she began to suffer almost constant pain in the left iliac fossa, and also from dysmenorrhœa and menorrhagia. Six months before coming under observation she is said to have had an attack of pelvic peritonitis. When she was admitted to the New York Hospital she complained of constant pain in the pelvis, and an examination showed a hard mass behind and on each side of the uterus. The tubes were removed by operation, the ovaries being left behind. Each tube was 2 to 2½ ctm. in diameter, and their walls about seven mm. in thickness. Microscopical examination showed the lesions of an ordinary chronic salpingitis.

A Calculus in the Substance of the Kidney.—Dr. Biggs then exhibited a calculus which had been found in the substance of a kidney. Its presence was not discovered at the autopsy, but the calculus was found in the fragment of the kidney which had been removed for microscopical examination. The subject was a man, fifty-eight years of age, who died of acute miliary tuberculosis. He had a history of acute articular rheumatism, but denied all knowledge of any acute nephritic trouble, although an examination of the urine before death showed the presence of albumin and casts. The only other lesions found besides those of tuberculosis were the lesions of chronic diffuse nephritis, and a few small cysts. The calculus was round, and completely filled a small cyst in which it was found. It was situated midway between the hilum and the convex border.

An Accessory Spleen in the Tail of the Pancreas.—Dr. Biggs also presented a small spleen which had been found buried in the tail of the pancreas. Microscopical examination of this mass, as well as of another near by, and also distinct from the spleen, showed typical splenic tissue.

Diffuse Sarcoma of the Mucous Membrane of the Uterus.—Dr. Warren Coleman presented a specimen of diffuse sarcoma of the mucous membrane. About one year ago he received from Dr. James H. McIntosh, of Newberry, S. C., a portion of a growth removed from the uterus by curetting. On receiving word that the growth was a sarcoma, it was decided to perform vaginal hysterectomy, and after the operation the uterus was put in alcohol and forwarded to him. On making a vertical section the cavity was found almost entirely filled with a soft, succulent mass of a light pink color, closely adherent to, but not invading, the uterine wall. The external os was patulous, measuring 2.5 ctm. in its lateral, and 1.2 ctm. in its antero-posterior diameter. The Fallopian tubes were not enlarged, and on gross examination appeared to be normal. A microscopical examination was made of the neoplasm, the cervix, the vagina, the wall of the uterine body, the fundus, and the Fallopian tubes.

The tumor was found to be composed chiefly of large round cells, with a slight admixture of spindle cells, and with giant-cells scattered throughout the mass. The cells were packed closely, and held together with a small amount of cement substance. No stroma could be demonstrated. The vascular supply was so plentiful as to suggest in places an angio sarcoma. The cervix was normal except for moderate senile changes, and the vagina likewise appeared healthy. The wall of the body of the uterus showed an absence of the mucous membrane, and the sarcoma had extended down to the muscle, but ended abruptly here. At the line of junction an occasional giant-cell could be seen, and also a slight round-cell infiltration of the muscular tissue. At the fundus the new growth dipped down into the substance of the wall, but did not actually invade it. Numerous thin-walled blood-vessels passed from the uterus into the tumor. In the Fallopian tubes the sarcomatous tissue was found creeping along under the mucous membrane and dislodging it, and considering the comparatively small extent of the process in the uterus itself it was surprising to what a distance it reached in the tubes—8 to 12 mm. In several of the reported cases the disease had extended through the tubes in the form of a plug, which in one case projected from the fimbriated extremity. In the present case a small vessel in the wall of one of the tubes contained a thrombus composed of sarcomatous elements.

The patient from whom this uterus was removed was sixty-seven years of age, and was attended by Dr. B. W. Taylor, of Columbia, S. C. She had had seven children. The menopause came on at the age of fifty-five, and was accompanied by no unpleasant symptoms. About a year and a half before the time of the operation a blood discharge from the uterus was first noticed. She was curetted twice, with temporary benefit. Shortly after the operation she began to suffer from abdominal pain, and two weeks before her death the bloody discharge returned. On January 26, 1893, she became paralyzed on the left side, and passed into a coma which ended in death three days later. No autopsy was obtained, but an examination before death revealed a tumor occupying the right iliac region, measuring 10 × 5 ctm., and another below the umbilicus, measuring 7 × 15 ctm. The vaginal roof was filled with a soft growth which broke down and bled freely on manipulation.

According to M. Terrillon uterine sarcomata may be divided pathologically into three varieties, viz.: 1, Sarcoma of the mucous membrane; 2, interstitial sarcoma; and 3, cystic sarcoma. The interstitial occurs in two forms, a circumscribed form which is often pedunculated, and another variety characterized by an enormous hypertrophy of the uterus. In the cystic form the cysts have thick walls and contain a bloody liquid.[1]

The speaker said that it is often stated that sarcoma of the uterus is a rare disease, but on looking up the literature of the subject he found that as early as 1870, Gussenow had collected 62 cases, and in 1874 A. R. Simpson added 4 to this list. He had himself found 45 cases which had been reported during the last five years after microscopical examination had established the diagnosis of sarcoma, and also a good many other cases reported under various names, but with a history which clearly showed that they should have been classed as the interstitial or cystic sarcomata of Terrillon. When we take into account also the "recurrent fibroids" and "fibro-

[1] See Gazette des Hôp., lxiii. 1269, Paris.

plastic tumors" of the earlier writers, and the "fasciculated cancers" of Rokitansky, the number of sarcomata of the uterus will be materially increased. Thomas says that many cases have been regarded as cancer, and not a few of the supposed fatal fibroid or polypus have been unquestionably of this affection.

Dr. Coleman then exhibited a microscopical specimen of the growth.

Aneurism of the Thoracic Aorta.—Dr. E. Hodenpyl presented for Dr. Huntington specimens taken from a dissecting room subject. They represented a fusiform aneurism of the aorta just at its junction with the heart, and an aneurism of the thoracic aorta, which he understood had ruptured into the thoracic cavity, and had also passed through the diaphragm into the abdomen. The cause of death was unknown, but as there was a fracture of the skull it is quite probable that he met a violent death.

Dr. George P. Biggs remarked that there might have been an opening formed in the diaphragm as a result of post-mortem digestion. He had recently seen a case in which an opening about three inches in diameter was made in this way.

Intestinal Obstruction from Twisting of the Bowel.—Dr. Hodenpyl then presented a specimen, removed at autopsy, from a man who had had symptoms of intestinal obstruction. The patient was a laborer, who while overheated drank a large quantity of ice water. He was immediately seized with abdominal pain and vomiting. After remaining at home in this condition for two days he was admitted to the hospital. On admission there was severe abdominal pain and vomiting, moderate temperature, and an exceedingly feeble pulse. A diagnosis was made of intestinal obstruction, but his condition was such that it was not deemed advisable to operate. He died four days later. At the autopsy all the organs except the intestines were normal. The appendix was found bound down behind the cæcum, and there was evidence of a small perforation. The principal lesion consisted in a twist of the small intestine about two feet above the ileo-cæcal valve. The intestine for some distance above this point was congested and very much distended with fluid fæces.

The Society then went into executive session.

Female Medical Practitioners in Russia.—An article has recently appeared in the *Siéverny Viestnik* upon the position of the woman doctor in Russia. The author of the article, Dr. Herzenstein, brings forward evidence to show that her position is improving every year, and that the demand for her services, particularly in the treatment of women and children, is constantly increasing. The number of women doctors in Russia has been reckoned at about seven hundred. The article advances statistics of 409 of these. Many of them occupy responsible positions in the service of the zemstvos, 21.27 per cent.; municipal bodies, 3.18 per cent.; in hospitals and workhouses, 14.42 per cent.; in educational establishments, 4.16 per cent.; in government institutions, 0.73 per cent.; and in factories and works of various sorts. Individual incomes from such sources vary from small sums up to 2,000 roubles (about £200 per annum), 8 receive less than 200 roubles, 43 receive from 200 to 500 roubles, 96 from 500 to 1,000 roubles, and 47 from 1,000 to 2,000 roubles, while 1 receives more than the last named sum. Incomes from private practice vary from 100 roubles to (in one case only) as much as 18,000 roubles per annum, the average income of a Russian woman doctor being less than 3,000 roubles. The large majority (280 out of 409) of women practising medicine in Russia are natives of the country; 98 out of 409 are Jewesses, and the remainder is made up of 8 Poles, 6 Germans, 3 Lithuanians, 1 Armenian, and 13 women of unknown nationality.—*The Lancet.*

Chloride of Gold and Sodium in diabetes mellitus, $\frac{1}{20}$ grain three times daily.—Robinson.

Therapeutic Hints.

Irritable Heart.—

℞. Chloralamid..... ʒ iv.
Tinct. belladonnæ..... ʒ ij.
Elixir simplic.....q. s. ad ʒ iv.

M. Sig.: Teaspoonful three times daily, between meals and at bedtime.

—Egbert.

Typhoid and the Brand Bath.—Although I first adopted the method on account of the statistics, I have continued it on account of the good effects which I have personally observed upon the condition of the patients, which no article of the materia medica is able to bring about. It is supporting and refreshing *only*, and not at all depressing.—Sihler.

Cactus Grandiflorus, in tincture made by macerating four ounces of fresh stems in a pint of strong alcohol for a month, has been found useful in functional heart disorders, relieving palpitation and nervousness. It seems to act chiefly on the accelerators and sympathetic ganglia, shortening diastole and stimulating the special vaso-motor system.—Watson.

Resorcin, combined with cocaine, is said to do away with the unpleasant effects of strong solutions of the latter.

Morphine is useful in some mitral affections, calming dyspnœa and nervous symptoms, producing diuresis and diminishing anasarca.—Hervouet.

Keratitis is pre-eminently a disease of the poor, the ignorant, and the careless. He who does much to tone up the average general health of the community will do something to prevent keratitis.—Roosa.

Diarrhœa Incident upon Teething.—

℞. Acidi sulphurici dil..... gtt. xij.
Morphinæ sulph..... gr. ½.
Spir. vini gallici,
Syr. zingib. .....āā ʒ ss.
Aquæ.....q. s. ad ʒ iij.

M. Sig.: ʒ j. every three hours.

—Meigs.

Give me quinine, opium, calomel, and jalap, and you can throw all the rest of the materia medica out of the window.—Gross.

Nervous Otitis.—Seek for dental caries, ulceration of mouth and larynx. Iodide of potassium, quinine, salicylate of soda, antipyrin, phenacetin, have given some good results. The negative electric pole should be tried.—Gompers.

Hemorrhoids.—

℞. Cocaine..... gram. 1.20
Morphine ..... centig. 30
Atropine ..... " 20
Tannin ..... gram. 1.20
Vaseline ..... " 30.00

Apply after each passage.

Chronic Congestion of the Larynx.—

℞. Creosote ..... gram 15
Carbonate of magnesia..... " 6
Distilled water ..... " 90

Teaspoonful in a pint of boiling water as inhalation.

Dry Rhinitis.—

℞. Oil of eucalyptus ..... gtt. xx. to ʒ j.
Vaseline or lanoline ..... ʒ j.

Apply to mucous membrane.

—Browne.

Goddard's Gargle.—

℞. Aluminis..... ʒ ij.
Cort. granati ..... ʒ ss.
Petal rosæ rub..... ʒ j.
Mellis ..... ʒ j.
M. Aquæ Bull..... ℥ vj.

The mixture can be used without dilution, or with an equal quantity of water.

Traumatic Tetanus.—Chloral, seven grains every hour, and four drops of freshly prepared fluid extract of calabar bean every two hours, in a boy of ten years, was followed by recovery after five weeks.—Radcliffe.

Diphtheria.—Continuous inhalation of the vapor from a mixture of eucalyptus oil, carbolic acid, and turpentine.—Smith.

Œdema of Glottis.—Three injections of pilocarpine at intervals of twenty minutes, amounting to $\frac{1}{2\frac{1}{2}}$ grain total, removed all dangerous symptoms within fifteen minutes of last injection.—Mendoza.

Eucalyptol in chronic bronchitis, chronic interstitial pneumonia, persistent cough, gives good results in five to ten minim doses in emulsion every four hours.—Brainerd.

Tuberculosis of Larynx.—

℞.	Tannin (pur.)	gram.	3
	Ac. carbol. cryst	"	1
	Aq. dest	"	300
	Glycerine	"	10

Use as spray.

Gastritis, dyspepsia, cancer of stomach, sea-sickness, vomiting of pregnancy.—

℞.	Hydrochloric acid	gram.	2
	Resorcin bisublim	"	2
	Syrup of oranges	"	20
	Water	"	178

A large spoonful every two hours; or,

℞.	Condurango decoction	gram.	180
	Rhubarb tincture	"	5
	Resorcin bisublimate	"	2
	Syrup of oranges	"	20

℥ ss. every two hours.

—Menche.

Microcidine.—Beta-naphthol and caustic soda fused together. Cheap, non-toxic, powerful antiseptic.

—Berlioz.

Atropine in small hypodermic dose is superior to all other remedies as a hæmostatic.—Bierwierth.

Chorea.—Fowler's solution till physiological effects. Fluid extract cimicifugæ in half-drachm doses. Hyoscyamine $\frac{1}{100}$ grain. Bromide of zinc.—Scurr.

Acute Rheumatism.—Cold applications to the joints afford almost immediate relief. It is best done by wringing out heavy towels in cold or ice water, wrapping about joints, and covering with flannel. These are renewed, and treatment kept up till cure is effected.

—Fraunfelter.

Treatment of Comedones.—Dr. H. von Hebra prescribes the two following solutions in the treatment of blackheads:

1. ℞. Rose-water,
Alcohol,
Glycerine āā ℥ ijss. (gms. 10).
Borax ℥ j½ (gms. 5).

Shake before using.

2. ℞. Green soap ℥ j½ (gms. 40).
Spir. lavender ℥ ijss. (gms. 80).
Alcohol ℥ ijss. (gms. 80).

Every morning wash the skin with No. 1, and then rub in No. 2. Then wash off with warm water.

Eczema of the Scrotum.—

℞.	Iodoformi	ʒ iij.
	Zinci oxidi	℥ jss.
	Spirit. camphoræ	ʒ iij.
	Aquæ calcis,	
	Olei lini āā	℥ jss.

M. Sig.:—Apply locally at night, and have patient wear suspensory bandage.

—Campbell.

Some Maladies hitherto ascribed to vague and unknown causes of internal origin are really traceable to infection, usually from without. This was illustrated by the cases of—(*a*) erysipelas, (*b*) impetigo, and (*c*) boils and carbuncles. All forms of impetigo are contagious; hence the term "impetigo contagiosa" does not represent a distinct disease.—Smith.

Erythema Nodosum treated with antipyrin (3 to 4 grammes daily for an adult) runs its course in eight to fourteen days.—Crentz.

Exfoliative Dermatitis, as well as other skin diseases, often show good effects from tartar emetic ($\frac{1}{8}$ grain three to five times daily).—Jamieson.

Lupus, Impetigo Contagiosa, and Pemphigus.—

℞.	Thumenol	gram.	2.5–5
	Flor. zinc,		
	Bismuth subnitrate āā	"	2.5
	Ung. lenit.,		
	Ung. simpl āā	"	25

—Neisser.

Impetigo of the Scalp.—Essence of turpentine applied twice daily and rubbed in with finger-tips. After five minutes wash with carbolic soap.—Serbs.

Oozing Eczema of hairy parts, particularly of the head, is soon reduced to dryness by a ten per cent. salicylic ointment.—Veiel.

Genital Herpes.—

℞.	Tannic acid	gram.	5
	Subnitrate of bismuth	"	1
	Powdered starch	"	100

Apply after washing with carbolic solution.

—Besnier.

Hyperidrosis Pedum.—

℞.	Naphthol	5 parts.
	Glycerine	10 "
	Alcohol	100 "

Apply locally twice a day, after which a powder composed of two parts of naphthol and 180 of starch is placed between the toes.

—Brocq.

Favus.—

℞.	Hydrarg. corrosiv	centigram.	12
	Alcohol, q. s.,		
	Petrolei,		
	Ol. olivar āā	gram.	15
℞.	Alcohol absolut	gram.	30
	Iod. pur., q. s. to obtain a saturated solution.		

For external use sponge and rub the favus spots and the adjacent surrounding skin, one day with the first solution, and the next with the iodine solution. Continue until a slight irritation of the skin supervenes, then interrupt the treatment a few days and apply an indifferent salve, when the treatment may be recommenced.

—Kerley.

Scrofuloderma and Lupus.—

℞.	Zinci oxidi,	
	Amyli pulv āā	½ oz.
	Vaselini albi	½ oz.
	Hyd. oleatis, 5 per cent.	1 oz.
	Acidi salicylici	gr. xx.
	Ichthyolis.	♏ xx.
	Ol. lavendulæ	q. suff.

M. Fiat ung. coloratum.

—Brooke.

Scabies.—

℞.	Creoline	5 parts.
	Vaseline	100 "

Mix. Use with friction, once every day, over the parts affected.

—Lollis.

Psoriasis.—

℞.	Ethylate of sodium	gram.	20
	Olive oil	"	80

Frictions.

—Gamberini.

Ulcers, Itch, Psoriasis, Eczema, Pruritus.—

℞.	Resorcinol (resorcin and iodoform compound)	gram.	5
	Venetian talc	"	20

Use as powder.

Biëlajew.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

FUNERAL OF SIR ANDREW CLARK—PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS—ROYAL MEDICAL AND CHIRURGICAL SOCIETY—MEDICAL SOCIETY OF LONDON—STRANGULATION OF TESTICLE—NEPHRECTOMY IN HYDRONEPHROSIS—PREVALENCE OF INFECTIOUS DISEASES.

London, November 18, 1893.

Sir Andrew Clark has been buried a week to-day. During that period his life, work, and death have been the chief topics of conversation wherever medical men met. The service in Westminster Abbey was most imposing. To his immediate friends and relatives, with all its sad solemnity, it could not but be some source of consolation that such a crowded assembly, composed largely of his professional brethren, should have been gathered together in the great abbey to bid farewell to the honored dead. A great multitude thronging the old cathedral and extending along the route of the procession, was a testimony to the esteem in which he was held, and an honor almost unique for a physician to attain to. The scene in the little churchyard near the deceased's country-house, though shorn of the pomp of the abbey service, was none the less affecting. With a simple service the body was committed to the grave, in the presence of the many friends and colleagues who had followed to take their part in the last offices of respect for the esteemed and beloved dead. R. I. P.

It was not in human nature to refrain from speculation as to the presidency of the College of Physicians. It will be a difficult thing to succeed Sir Andrew Clark. The college, indeed, numbers in its ranks many who, for some reason or other, are worthy of its highest honor, and capable of discharging all the duties of the position. Consequently many names have been discussed and their several qualifications canvassed. Among these, perhaps, Dr. Russell Reynolds may be thought to combine most of the qualities to be desired. An election of this kind is, however, often most uncertain.

On Tuesday, the 14th inst., the chair was taken at the Royal Medical and Chirurgical Society by Dr. Church. At the previous meeting, as I have reported, the session was opened by a vote of sympathy with the family of Sir Andrew Clark, their president, on his serious illness. At this, the succeeding meeting, the first business was a resolution expressing the sense of irreparable loss sustained by the society, and sympathy with Lady Clark and the family in their bereavement. Dr. Church paid a touching tribute to the memory of the late president, and related the course taken by the council under the sad circumstances; for no president has previously died in office, although the society has been established more than eighty years. Consequently there was no precedent for the officers. Their action was quite approved.

On Monday last (13th inst.) the President, Dr. Bristowe, opened the meeting with a few touching remarks on the loss sustained by the death of Sir Andrew Clark, after which Mr. Owen related a case of strangulation of the testicle by axial rotation of the cord, and urged the propriety of removing the organ in these cases.

Mr. Bland Sutton then read a paper on the indications for nephrectomy in hydronephrosis. Observing that hydronephrosis is mostly due to obstruction, he insisted that this must be incomplete or temporary, or otherwise rapid atrophy would ensue rather than dilatation. As a rule, he said, it ran a latent course. When unilateral the diagnosis might be difficult, but when bilateral the intermissions might alternate. In the latter case the only symptoms might be frequent micturition until the kidney substance was reduced below the physiological needs, whereupon uræmia suddenly appeared. Though hydronephrosis remained unperceived until very large, should suppuration occur symptoms immediately called attention to it. It is necessary to distinguish this condition from primary pyonephrosis, which is seldom large and is mostly associated with calculus, calling for nephrotomy rather than nephrectomy. As to hydronephosis suppurating, Mr. Sutton remarked that when very large it often came into close contact with the colon, the walls being so thin that osmosis could take place. He objected to aspiration for diagnosis, as it exposed the patient to danger and was often misleading.

Mr. Alban Doran advocated delay of operation when associated with floating kidney, and related a case in which the condition subsided of itself. He could not admit that real atrophy necessarily occurred, as he had specimens showing the kidney substance normal.

Mr. H. Morris observed that the original cause of obstruction was not always found, as it might disappear during or after the forming of the hydronephrosis; he pointed out, too, obstruction of the ureter low down did not necessarily cause dilatation right up to the kidney, as a pouch was sometimes formed and might press on the tube higher up, as an aneurism might do. He recognized a thin-walled variety which collapsed on tapping, and a second kind in which there was hypertrophy of the kidney substance, so that when the calices were laid open they were seen to be thick-walled and separated by fibrous septa; and this was specially likely to occur when one kidney atrophied or was removed while its fellow was undergoing dilatation. He thought that such organs should sometimes be dealt with as if they were solid tumors.

Cholera has left us, but small-pox and scarlet fever still prevail. The former has lately spread a good deal in different parts of England. The difficulty of providing hospitals for infectious diseases continues and has been mentioned in Parliament.

Diphtheria has extended. A serious epidemic has occurred in Essex, and another outbreak is reported at Oxted, in Surrey.

Influenza is again appearing; at Birmingham and Blackburn it is very rife, although it is said the type is not severe. Here in London many mild cases are met with, but the prostration which succeeds the attack is often very great.

A RESPONSE FROM DEMILT DISPENSARY.

To the Editor of the Medical Record.

Sir: In your editorial of November 25th on "Doctors and Dispensary Boards" you question the truth of my statement that dispensaries managed in whole or in part by medical men are the worst in the city. I might easily offer proof of my assertion; but to specify instances would be unwise and would not settle the question. I am convinced that should a fair-minded committee of medical men investigate the management and work of all the dispensaries, they would reach the conclusion that a managing board of laymen in close touch with the faculty is the most efficient in carrying out the design of such institutions. This policy was adopted in the organization of the Demilt Dispensary, forty years ago, at the suggestion of a father in dispensary and hospital management. We have found the advice so sound and its results so satisfactory to our medical staff that we commend it to other institutions. I know well that "there are plenty of physicians who possess both professional knowledge and business capacity." This fact does not have any bearing upon my assertion, which was that the best management is an exclusively lay board, and the worst a mixed lay and medical board. In passing, let me point out one advantage of the lay system; the fact that under it appointments are uninfluenced by questions of medical politics or medical-school prejudice; the appointing officials are not subjected to the pressure brought to bear upon doctors acting in such a capacity. Surely no more convincing proof can be asked of the esteem in which the lay board of the Demilt is held than the list of eminent physicians

who have served it in the past, and the professional standing of those on its staff to-day.

The managers have failed to discover that "the Demilt Dispensary, which used to stand in good repute among the profession has lost much, if not all, of its prestige through the narrowness of its managers." Mr. Editor, "we trust that you have facts to sustain this remarkable statement." We regret that the proofs should have been withheld. We, at least, have never been aware of the existence of any of the "friction" apparently common elsewhere. I doubt whether two sets of men have ever worked together more harmoniously than have our managers and physicians. Occasional disagreements have arisen, as they will in any live organization; but, considering the number of years since its incorporation, and the large number of changes among the managers and doctors during that time, the differences have been very few indeed. No request of our physicians has ever failed to receive careful consideration and favorable reply when the latter was possible. We flattered ourselves that we stood pre-eminent in this respect. Such has been the testimony of many physicians. When we have been obliged to refuse we have given good and equitable reasons for so doing.

As a matter of fact the number of patients treated at the Demilt has increased twenty-five per cent. in the period in which you state that there has been no increase. Granting that your assertion is correct, we do not think that the increase of patients should be the test of its usefulness or even a source of satisfaction to a dispensary. When the Demilt was opened, in 1851, there was no medical charitable institution above Fourteenth Street. There are now eight in the district we cover. We only regret that our numbers have not diminished. In this respect I most heartily agree with the opinion so often expressed by you in times past, for I do not look upon the increase in attendance as a sign of merit. On the contrary, it should arouse anxiety lest it results from some abuse of our charity. Any such we wish to correct.

CHARLES C. SAVAGE.

Report of the Committee on "The Practice of Obstetrics by Midwives."—In presenting a proposed amendment to the medical laws of the State of New York, involving the practice of obstetrics by midwives, the committee appointed by the Medical Society of the County of New York desires to call the Society's attention to the following facts: 1. There is at present no law in the State of New York for the regulation of midwives in the practice of obstetrics. Any person can so practise after registering and paying a fee of fifty cents. 2. The number of persons at present acting as midwives in the city of New York is thought to be over three thousand. 3. The number of births reported annually by midwives is within a few hundred of the number reported by physicians. That number is about twenty-five thousand. 4. In the matter of still-births, the per cent. here is nearly three times greater than with the midwives in Berlin where the practice is regulated. 5. There is good reason for the belief that criminal abortion is frequently practised by some of the midwives of this and other cities of this State.

In considering means for improving the anomalous situation at present existing in this State, namely, that physicians who devote years of study in preparation for obstetric and other work are not allowed to practise until stringent requirements have been met according to law, while the most ignorant, by classing themselves as "midwives," can without question care for women passing through that perilous "physiological process," childbearing, the committee has considered the following questions: 1. Should the practice of obstetrics by midwives be done away with altogether? 2. If so, could it be prevented? If allowed, should means for the education of midwives be established? 4. How much preliminary qualification should be required? 5. Would not limited requirements, a reasonable registration and fee, and strict limitation of their obstetric privileges, by which a large per cent. of cases would be thrown into the hands of physicians, prove most feasible?

Without going too minutely into the details of the views and arguments expressed, it was the unanimous opinion of the committee that, on the one hand, the trend of obstetrical practice is and should be toward a scientific level beyond the possible attainment of midwives, and that the latter are an importation which should not be cultivated as a branch of our profession; but that, on the other hand, it would not be feasible to undertake their complete removal. Stringent requirements as regards antisepsis, and close limitation of the midwife's practice to the most normal conditions, requiring that a physician be summoned for all abnormal conditions, and the restriction of her license in not permitting her to make returns of still-birth or treat puerperal diseases—these, it was thought would bring about the best results. Similar methods have been put to the test in other States, New Jersey, Illinois, Minnesota, and in Erie County, this State, with most marked improvement. The number of midwives practising has been reduced, the per cent. of still-births lessened, the development of fevers greatly reduced, and criminal malpractice brought nearer the eye of the law. Your committee unanimously proposes the following as in its opinion a much needed amendment to the present medical laws of the State of New York:

An Act to Regulate the Practice of Midwifery in the State of New York.

1. Be it enacted by the Senate and Assembly of the State of New York, That every person practising midwifery in any of its branches shall possess a certificate from the State Board of Medical Examiners as hereinafter provided.

2. And be it enacted, That every person now practising midwifery in the incorporated cities of this State shall, within thirty days after the passing of this act, personally present to the State Board of Medical Examiners an affidavit setting forth the name, nationality, age, authority, location, and length of practice, together with a certificate of good moral character from some registered physician, resident of the same district; whereupon the Board, on receipt of a fee of one dollar, shall issue a certificate, signed by its President and Secretary, and bearing the seal of said Board, entitling the person named therein to practise midwifery in this State.

3. And be it enacted, That every person hereafter beginning the practice of midwifery in this State shall appear before the State Board of Medical Examiners and submit to such examinations in midwifery as the Board shall require, and if such examination is satisfactory to the examiners, the said Board shall, upon the receipt of a fee of five dollars, issue a certificate the same as provided in section two of this act.

4. And be it enacted, That the person so receiving

said certificate shall file the same with the clerk of the county in which she resides, and said clerk shall file said certificate and enter a memorandum thereof, giving the date of said certificate and the name of the person to whom the same is issued, and the date of said filing, in a book to be provided and kept for that purpose; and for which registry the said clerk shall be entitled to demand and receive from each person registering the sum of twenty-five cents.

5. And be it enacted, That the State Board of Medical Examiners are hereby authorized and empowered to execute the provisions of this act, and shall hold examinations of candidates for certificates in midwifery at such times and places as may be deemed by them expedient.

6. And be it enacted, That the State Board of Medical Examiners may refuse licenses to persons of bad character or guilty of unprofessional or dishonorable conduct, and may revoke licenses for like cause, or for neglect to make proper returns to the various health officers of births.

7. And be it enacted, That this license does not give any person practising midwifery within the meaning of this act the right to perform version or treat breech or face presentations, or do any obstetric operation requiring instruments, or treat any abnormal condition, except in emergency, or make returns to the various health officers of still-births, or puerperal diseases, but shall call in a qualified physician to treat the same.

8. And be it enacted, That any person shall be regarded as practising midwifery within the meaning of this act who shall publicly profess by advertisement, sign, card, or otherwise to be a midwife, or who shall for a fee attend to women in childbirth, but nothing in this act shall be construed to prohibit gratuitous service in case of emergency nor to the legally qualified physicians or surgeons of this State.

9. And be it enacted, That any person practising midwifery in this State without first complying with the provisions of this act, shall be guilty of a misdemeanor and shall be punished by a fine of not less than ten dollars nor more than fifty dollars, or by imprisonment in the county jail for not less than ten nor more than thirty days, or both, in the discretion of the court.

10. And be it enacted, That all acts or parts of acts inconsistent herewith be, and the same are hereby, repealed, and that this act shall take effect immediately.

Respectfully submitted,

EDWARD A. AYERS, M.D., *Chairman*,
SIMON BARUCH, M.D.,
HENRY R. DRAYTON, M.D.,
S. SEABURY JONES, M.D.,
HERMAN L. COLLYER, M.D., *Committee*.

A Strange Suggestion.—It is reported that King Oscar, of Sweden, offered to place a government cruiser at the disposal of the members of the National Medical Society. The intention was not that the Society should go off for a quiet sail as a recreation after the close of their scientific labors, but, as His Majesty suggested, that all the meetings should be held aboard ship upon the high seas. The inference is that the king regarded the presence of so many doctors on shore as highly objectionable.

Mortality from Overcrowding.—Dr. L. Lander writes: "In your report of the discussion which took place at the meeting of The County Medical Association, October 28th, on the subject of "The Dangers to Public Health from Overcrowding of Population," I am credited with the statement that 'The mortality of those (tenement) districts was almost fifty per cent. higher than in private dwellings.' Your reporter misunderstood me. I did not say that. What I did say was that in some districts, where tenement-houses only are found, the comparative mortality was about fifty per cent. greater than it is in the districts of fine residences; which is a very different statement. In this connection I beg to call attention to the statement of Mr. Marcus Reynolds, noticed editorially in a late number of the MEDICAL RECORD, that 'The death-rate of the tenement population of New York is slightly lower than that of the remaining population;' and I would refer Mr. Reynolds to the statistics of the Board of Health, which seem to be widely at variance with his statement. It should also be remembered that 'the remaining population,' spoken of by Mr. Reynolds, includes the hospitals, the almshouses, the penitentiary, and the asylums, in which the death rate is very much higher than it is in 'the districts of fine residences' which I mentioned."

The Tooth pick in Respiratory Gymnastics.—The practice of inhaling medicines, says Dr. Charles Denison, properly comes under the head of respiratory exercise. So much so, that I very much doubt if the atomized antiseptics, or whatever is inhaled, have the good effect ascribed to them; but rather the effect is due to the respiratory gymnastics necessitated in the process of inhalation. The truth is, except in the upper air-tract, the medicaments do not ordinarily reach the infected portions. The fibroid process of healing—in other words, the incapsulation of tubercle, which is the most prominent feature of the natural arrest of chronicity of lung tuberculosis, tends to close or shut off the affected portions from the inhaled air. In this protecting policy the whole lung is more or less implicated, and the inspired remedy goes with the inhaled air to the unaffected lung on the other side. For this reason a great deal of the inhalation treatment, so popular with certain specialists, is utterly useless; or, by irritating sound lung areas, is positively harmful. For this reason the utility of exhaling tubes is explained. The principle involved is the secret of a peculiarly successful form of respiratory gymnastics. The idea is to inhale freely and fully, but to exhale with effort, and with restraint or some obstruction to the outgoing air. Thus the density of the expansive air within the thorax is so much increased, that it will work its way into areas of lung where otherwise some air-cells would be unused but for this prolonged effort. Again, some congestion or infiltration might still remain in out-of the-way lung-spaces, were it not for the *push* given to the blood circulation by the increased pressure of this pulmonary air, thus (during this forced expiratory effort) thrown into marked contrast to the rarefaction existing there during inspiration. This process of breathing is much like the natural stimulus of altitude. If assiduously practised, it is an invaluable exercise. But it is unnecessary to resort to any secret or extensive apparatus, except that to some people mystery enhances any good they are to receive. A large tooth-pick, three-fourths to five-sixths plugged at the outer end, or a small glass pipette or dropping-tube, with nozzle large enough to just about take in the head of a pin, will answer the purpose quite well.

Chromic Acid and Glycerine should not be prescribed together, as the mixture is explosive, so says a writer in an English journal.

An Antiseptic Varnish.—Dr. Berlioz, of Grenoble, gives the following formula for an antiseptic varnish which he calls sterisol:

℞.	Gum lac (purified, very soluble in alcohol)	ʒ ix.
	Powdered benzoin	ʒ ijss.
	Tolu balsam	ʒ ijss.
	Crystallized phenic acid	ʒ iij.
	Essence of cinnamon,	
	Saccharine	āā ʒ jss.
	Alcohol	ad Oij.

The employment of this varnish is indicated wherever there is abrasion of the mucous membrane, as in diphtheria, mucous patches, herpes, etc. It adheres to the mucous membranes as well as to the skin, over which it forms a thin pellicle.

Chancre of the Tonsil is characterized by enlargement of the tonsil, extreme hardness, superficial ulceration marked by sharply defined edges, and enlargement of the neighboring lymphatic glands.—BULKLEY.

THE HISTORY OF THE DISCOVERY OF THE OPHTHALMOSCOPE.[1]

By PROFESSOR HERMANN v. HELMHOLTZ,

BERLIN, GERMANY.

PROFESSOR KNAPP, after introducing Professor Helmholtz, Mr. Alexander Graham Bell, and President Seth Low, spoke as follows:

GENTLEMEN: Professor Helmholtz has kindly accepted an invitation to speak to you about the discovery of the ophthalmoscope, and I think it opportune to preface his address by some historical remarks on the development of ophthalmology. I shall be exceedingly brief and go over the field with very rapid strides.

Ophthalmology is one of the oldest branches of medicine on record. We find in the hieroglyphics of the old Egyptians a full account of the eye remedies that were used at that time. They are collected in the so-called Papyrus Ebers, which is preserved in the library of the university of Leipsic, a German translation of which I pass round. It dates from the eighteenth Egyptian dynasty, certainly more than fifteen hundred years before Christ. The remedies are very quaint; some good, which we still use, and some full of superstition and filth. The Egyptian physicians were priests, and to your consideration I recommend two of their customs. One was that no remedy should ever be applied without an invocation to the gods (with such and such a salve, such and such a prayer had to be pronounced!); the other, that they were bound by an orthodox rule to use no new remedy or a new method of treatment which was personal to any one of them; for they said that the power of any one mind was so small compared with the accumulated wisdom of ages that it counted for nothing. The latter is evidently a rule which would bar progress. Nevertheless, you can see in what spirit it was given. At that time, I dare say, a number of remedies were made known for personal reasons, just as to-day a multitude are claiming our attention of which only an infinitesimal part are better than what we had before. Innovation is not identical with improvement. An inquiring mind will always be carried toward conservatism, and conservatism is certainly just as commendable in medicine as in anything else. It is truly a good rule that nobody should use a new remedy before he has fully acquainted himself with the acquired stock of knowledge that has stood the test of time.

The healing art passed from the Egyptians to the Greeks, to the Romans, to the Arabs. I need only refer you to the works of Hippocrates, Galen, etc. In the middle ages there was a healing art and also an ophthalmology. As a curiosity I pass round a quaint volume. It is by Bartisch, of Königsbruck, in Saxony, and dates more than three hundred years back. In it there are a number of procedures mentioned which are still in use, but the majority of them are valueless. In the eighteenth century ophthalmology was cultivated in Italy and France. The most important invention practical ophthalmic surgery has ever made was the extraction of cataract by Jacques Daviel, in 1757.

Toward the end of the last century ophthalmology was recognized as an essential department of medicine, and special eye hospitals were built in the larger cities—London, Vienna, and very soon after in New York, Boston, and Philadelphia. The Eye and Ear Infirmary at Second Avenue and Thirteenth Street is the oldest and largest in this country. Ophthalmology progressed *pari passu* with general medicine, fostered by the development of natural science, anatomy, physiology, and pathology. In England, in the first half of this century, ophthalmology was zealously studied. The acquired knowledge of eye surgery, up to 1847, was carefully collected in a classical treatise of eleven hundred pages by William Mackenzie, of Glasgow. It presents the ante-ophthalmoscopic period of ophthalmology so completely and truly, that it will remain a landmark in medical history.

In the year 1851 Professor Helmholtz invented the ophthalmoscope, and introduced a new epoch for ophthalmology. It was an event in science opening a field which to all previous ages had been impenetrably dark. To view the background of the eye with a magnifying power of about sixteen diameters, to see the optic nerve, the retina, the blood-vessels, and a multitude of other physiological and pathological conditions, was a thing for which the world was so utterly unprepared that you can imagine what wealth of discoveries followed in its wake. The Professor will speak to you of the investigations that led to the discovery of the wonderful instrument, but allow me to bring to an end this rough-drawn sketch of the history of ophthalmology.

Immediately after the discovery of the ophthalmoscope it was taken up by men of great mental calibre—A. von Graefe, in Berlin, E. Jaeger, in Vienna, and others. At that time every look into the eye was a discovery, but the scope of the instrument is so great that even at the present time it is still the most powerful means of ophthalmological research. With it we can study, better than with anything else, pathological anatomy in the living. Hemorrhages and their changes, embolism, infarctions, thrombosis, inflammations of all kinds, foreign bodies, and a multitude of other anomalies, we can follow up with a precision that even surpasses that afforded by the post mortem table. Moreover, we do not only see the disease in one given condition; we watch its beginning, course, and termination; we have the natural history of the disease before us. The possibility objectively to determine with the ophthalmoscope the refractive condition of the eye and its many anomalies and degrees, is one of the finest accomplishments of the well educated physician.

Professor Helmholtz, however, did not stop at the invention of the ophthalmoscope. He went over the whole field of physiological optics. There was not the remotest corner that he did not personally cultivate, criticising, verifying, correcting, and broadening every branch of this immense and exceedingly beautiful department of natural science. The outcome is a classical treatise which I pass round, a whole storehouse of knowledge to which your teacher and a great many other retailers daily go to buy and borrow.

I will mention some of the most remarkable discoveries in optics, and advances made in ophthalmology, which, besides the invention of the ophthalmoscope, we owe to Helmholtz. One is the discovery of the mechanism of accommodation—that wonderful faculty by which the healthy eye is enabled to see objects near by and immediately afterward, with the velocity of lightning, others at an immense distance.

The mechanism of this faculty was not understood,

[1] Delivered at the opening lecture of Professor H. Knapp's Ophthalmic Clinic at the College of Physicians and Surgeons, New York, October 3, 1893.

though discussed for centuries, till Professor Helmholtz solved it through another instrument of his invention which you see here, the ophthalmometer. Up to that time it was thought that the extrinsic muscles of the eye compressed the eyeball and made it more spherical. This view had to be given up, because, though possible, it was not true. Some thought that the crystalline lens moved to and fro and changed the focus, just as the focus is changed in the photographer's camera. This view had also to be given up because it was not true. Professor Helmholtz found that accommodation was due to the action of the muscles called the muscles of accommodation, rendering the crystalline lens more convex, so that its refractive power becomes much greater.

An image reflected from a convex surface is smaller than the original object, the reduction in size being in proportion to the degree of convexity of the refracting surface. Professor Helmholtz measured the sizes of the images reflected from the lens when the eye was at a state of rest, and then again when it was under the strain of accommodation, and found that they had become smaller. As there had been no change of distance of the object from the eye, the difference in size between the images could be accounted for only by a change in the refractive power of the mirror, that is, the anterior surface of the crystalline lens. This proved true, and all discussion on this question was ended. It was a truth which, when once recognized, is a truth forever.

Professor Helmholtz not only discovered the law of accommodation, its existence, I may say the quality of this phenomenon; but, like a true natural philosopher, went on to ascertain its quantity. He measured how much smaller that image had become, and from the smallness of the image he could judge of the radius of curvature of the surface which produced it. This change of radius of curvature in the refractive power represented a quantity which was equal to what we call the range of accommodation.

This was the solution of this very obscure phenomenon which had occupied the best minds a long time. It was as fruitful as it was brilliant.

With the ophthalmometer, Helmholtz and his followers found the remarkable and very important fact that the eye is not a sphere: that its horizontal and vertical diameters are not equal. In other words, the eye is an ellipsoid, and therefore produces a very peculiar kind of refraction. It gives a dispersion image which terminates in two straight lines at right angles to each other. This peculiarity was soon recognized as a defect in all eyes, diminishing the acuteness of vision more or less. Its recognition enables us, by the use of cylindrical glasses, to correct defective vision in multitudes of people. By a modification of Helmholtz's ophthalmometer, made by Javal and Schiötz, the difference between the vertical and horizontal meridians can now be determined in a very short time—several minutes—and the correcting glasses prescribed.

Gentlemen, I might go on in this way, but I do not want to consume too much time. I only beg to say a few words still with regard to the usefulness of the ophthalmoscope as applied to practical medicine. I have here a few drawings to illustrate what can be done with the instrument. The examples in which the ophthalmoscope has proved useful, count by hundreds.

Here, on the wall, you see a picture of the normal background of the eye, and another in which the course of the blood-vessels is interrupted at the margin of the optic disk. This second picture represents the eyeball under increased tension, a disease which is called glaucoma. The eyeball being too tight, the pressure acts upon that part which is most feeble, most yielding—that is, the cribriform membrane through which the fibres of the optic nerve pass.

This disease is not infrequent, and up to 1858 was absolutely incurable. Then came Professor Albrecht von Graefe, of Berlin, who found for it a remedy, iridectomy, the cutting out a piece of the iris, whereby the increased intra-ocular tension was relieved and the disease cured. From that time forth every oculist has saved by this operation dozens of eyes every year. It was a great stride. Here also the diagnosis depended upon the ophthalmoscope. The ophthalmoscope is the best, the most accurate, and the most practical diagnostic instrument to which thousands of our fellow men owe the preservation of sight. Professor von Graefe with his astonishing clinical penetration, made many discoveries with the ophthalmoscope which were landmarks in the progress of ophthalmology.

Let me cite but one example. In 1858, Professor R. Virchow said in one of his lectures, it must be possible with the ophthalmoscope to see embolisms in the living, just as he and most other pathologists had seen them, on the post-mortem table. He said the retinal artery lies open to our view; it divides into two branches, and the time is probably not very far distant when this condition, embolism, will be directly seen, and then it can be studied with all its consequences. I was a student at the time when Virchow made that statement. A week later Von Graefe diagnosed the case at his clinic. He examined the eye by means of the ophthalmoscope, described the conditions present, and his description of embolism is still classical. Von Graefe was not only an excellent diagnostician and pathfinder, but also a great operator. His name ought to be mentioned as one of the first, if not the first, in practical ophthalmology.

Dr. Knapp continued his remarks by demonstrating ophthalmoscopic pictures of glioma of the retina and sarcoma; he dwelt upon the importance the anomalies of refraction and motility had gained of late, and concluded with a graceful tribute to the merit of a young oculist, Dr. Carl Koller, now in our midst, for having, in 1884, introduced the local anæsthetic cocaine into ophthalmic practice.

Professor Helmholtz then rose, and, greeted by the students with the most enthusiastic applause, spoke essentially as follows:

Gentlemen, Professor Knapp asked me to tell you the story of the invention of the ophthalmoscope. In complying with his request I must beg your pardon, first, for being obliged to speak of myself; secondly, for my insufficient command of the English language.

At the time when I devised the ophthalmoscope I was professor of physiology and general pathology in the University of Koenigsberg. My career before had been somewhat erratic. When at school my ardent desire had been to study physics, but physics at that time was a branch of science that did not promise its followers a good livelihood. It is different nowadays.

My father told me that he did not see how it was possible to maintain me in the study of physics or inorganic natural science alone, but if I would also take up the biological department, or practical medicine, he could help me, so I went to become a medical man.

What for the time was a great disappointment to me, afterward turned out to be a very lucky event, for it enabled me to become professor of physiology in the University of Koenigsberg. I lectured on all parts of physiology, and so came also to tell my hearers what was known of the human eye and of the eye of animals.

I think that no physiologist doubted, until the end of the last century, that the eyes of cats, dogs, oxen, and other mammals, and of birds, developed light of their own which shone forth at night. It seemed to them to be the same process as was observed in the luminosity of insects in the water, etc.

Prevost discovered, at the beginning of this century, that the eyes of mammals which appeared luminous possessed a peculiar anatomical structure, that is, what by anatomists is called the tapetum, situated on the background of the eye. This tapetum has a very resplendent surface, is composed of a peculiar kind of very fine fibres, of very regular thickness, which throw off colors like a layer of thin plates, as was discovered by Newton long ago. This light shone forth from the eye of

the dissected animal just as it did during life, so that it became very probable that the light of the living eye was really not light originally produced by any influence of the nervous system on this organ, but that it was reflected light. At first, however, physiologists who had to speak of these things were rather at a loss to explain how the light could get into the living eye. I must remark that the intensity of the light coming back from such a luminous eye is often very surprising. Even if there is no great amount of light in the neighborhood of the animal, the observer can sometimes see the eyes of the animal luminous in a very high degree.

From the time of Prevost, say about 1810, at least, doubt awoke as to whether this was not only reflected exterior light. Professor Brücke, of Vienna, made microscopical examinations of the tapetum and its relations to the retina, and endeavored to show that the animal having such a tapetum could get a stronger luminous impression from its retina than another without the tapetum. He said that if there is a tapetum and the light is reflected from the background of the eye through the pupil and back, then the light possesses twice its original luminosity.

About 1846 the English oculist, Dr. William Cumming, discovered that the experiment which had succeeded on the luminous eyes of mammalia could also be performed on the living human eye, and everybody's eyes could be made luminous. It is an entertaining experiment in a social gathering, and students have applied it to frighten young ladies.

The experiment is very simple. An animal or human being is put in a dark room, a light is placed at some distance in the background. The eye of the observer is nearly in a direct line between the two. The rays of the light pass alongside the head of the observer into the eye of the observed, are reflected back in the direction from which they proceeded, making the observed eye appear very luminous to the observer. The effect is very curious, giving the impression of seeing a spirit or any other supernatural phenomenon. This experiment was first made by Cumming, and afterward, independently, by Brücke.

Such were the facts known by scientific men in 1847, when I began to search for the ophthalmoscope. Brücke knew that the nearer the eye of the observer was to the line of light passing to the eye of the observed, the more luminous would the observed eye appear. But nothing had been seen of the interior structure of the seemingly luminous eye, the impression given being only that of a diffuse appearance of light covering the whole pupil.

In my lectures I had to give an account of these experiments, and to try to give an explanation of the phenomena. I was obliged, therefore, to seek for an explanation myself, and I may say that it was not difficult to find—at least for a man who had occupied his time with reading physics and chemistry, and in making experiments, as far as his scanty means would allow. Being acquainted with the principles of optics as far as they were then known, I proceeded to analyze the course of the rays of light in the experiment just alluded to, and thus reached an explanation of the phenomena, the correctness of which was afterward confirmed by the ophthalmometer.

If you have a luminous point from which rays of light go out into a room, you can, by the use of lenses or mirrors, cause those rays to be refracted or reflected in a line forming any angle, large or small, with the original course of those rays. You can even make them return in the same space which they originally traversed, and if all the rays are thus reflected a complete image is formed of the luminous object. Let the rays of light fall upon the retina and be from there reflected back through the refracting media of the eye, passing out to be united upon a single point outside. We should recall at this step the principle of optics, that when light proceeds from different luminous points, the rays when reflected fall upon the same points again. If, for instance, light proceed from A and B and pass through a refracting medium, or be reflected from a mirror and fall upon alpha and beta, it will be found that those rays proceeding from A fall upon alpha and not upon beta, and that those proceeding from B fall upon beta and not upon alpha. If the reflecting surface be the retina and the eye accommodated for the luminous body, then those of the reflected rays which had their origin at A will be reunited at A, and those from B will be reunited at B. In other words, none of the light starting at A will be reflected back to B, and none starting at B will be reflected back to A. Now, in the case of a luminous eye the observer obtains only an obscure image, because his own eye does not represent the point from which the rays originally started and at which they are united.

The human eye does not emit light, and therefore all that we see in it is the black ring of the pupil. Indeed, there are only two ways by which the eye can be made to appear luminous. One is to bring the luminous point very near to it, so that the eye cannot accommodate or arrange its focal distance to the distance of the luminous point, whereupon the latter forms only an irregular or diffuse image on the retina. A greater surface of the latter is illuminated from which rays of light can be thrown back into the room through the dilated pupil. If, then, the eye of the observer is at the proper distance and in line with the rays, he will be able to see some of the light which comes back. That is the case in the experiments of Cumming and Brücke, which were carried out in such a way that the image formed upon the retina was not sharp.

Now, one can make the diffusion of light in the interior of the eye still greater by putting a convex lens before the eye, the rays being united at the focal distance of the lens.

The Professor described and illustrated by numerous blackboard drawings how the rays of a light, placed at the side of two persons seated opposite each other, were thrown from a glass-plate, placed obliquely between them, into the eye of one, and passed through his pupil to the background of his eye. From the background they returned, the way they had travelled before, to the glass plate which reflected a part of them back to the light, whereas another part passed through the glass-plate into the pupil of the other person, and on reaching his retina made him see the pupil of the first person illuminated. A similar experience had been made by a student, Carl v. Erlach, after hearing a lecture of Professor Brücke, at Vienna. He was near-sighted, and accidentally the light from a gas flame fell upon his concave spectacles, was reflected into the eye of a fellow student, and made his pupil appear luminous to Erlach.

Professor Helmholtz continued: We have seen how it is possible to illuminate the eye by a light which is outside of the eye. The eye to be observed having been rendered luminous, there is only a second condition to be fulfilled, namely, to make it possible for the eye of the observer to accommodate itself to the focal distance of the one to be observed. That was easily done, it being only necessary to choose a lens of the proper focal distance. By placing it behind the glass-plate, the observer no longer sees a diffuse illumination of the pupil of the other person, but a picture of his retina in all its anatomical details.

All that was original with me in the matter was that I went to ask how the optic images could be produced by the light coming back from the illuminated eye. All my predecessors had failed to put this question to themselves. They had stopped in the middle of their way instead of going on to the end. As soon as I had answered that question I saw also how an ophthalmoscope could be constructed, and it took me only two days to do it and successfully to experiment with the new instrument. I say this to impress upon you how necessary and how useful it is to go on to the end when investigating natural phenomena. You must not go half-way and then stand still or go back; you must finish your meditations,

go to the end, so that you may see clearly the full relation of the several phenomena to one another Having followed the chain up, link by link, to its end; having traced the rays of light on their course from the flame into the eye of the observed, and shown what becomes of them when reflected, and how they can, by the interposition of proper lenses, be united on the retina of the observer and thus give him a distinct view of the background of the eye observed; that was the solution of the problem; and with that, gentlemen, my story is told.

DENUDED CRANIUM: ITS TREATMENT BY PERFORATION OF THE EXTERNAL TABLE OF THE SKULL AND THIERSCH METHOD OF SKIN GRAFTING, WITH REPORT OF CASE.[1]

By EDMUND M. POND, M.D.,

RUTLAND, VT.

FELLOW OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

R. P——, eight years of age, to avoid being hit by snow-balls while at play, ran into the basement of a saw-mill. The main shaft from the water-wheel ran through the room and in some way caught her hair, winding it upon the shaft and drawing her over twice, the first time sideways, the second backward, throwing the whole weight of the body upon the scalp, which was torn off.

The line of separation is clearly seen from the photographs, and runs from the root of the nose, through the right eyebrow, through the right ear, leaving only its lower lobe, downward and backward across the neck, exposing the insertions of the trapezius and sterno-mastoid muscles, upward and forward, removing the posterior part of the left ear, through the left eyebrow to the place of starting. Thus it is seen that the entire scalp was removed, leaving bare most of the frontal and parietal bones and part of the occipital.

I saw the patient for the first time, April 3d, ten days after the accident, and found her condition as follows: Pulse, 116, very weak; temperature, 100.6° F. The wound was septic, the muscles covered with an offensive gelatinous and purulent exudation. Most of the frontal, parietal, and occipital bones bare; the periosteum where present was dry as parchment. The bone was of a dull grayish color, dry except where bathed in pus from surrounding granulations.

Under ether anæsthesia the head and surrounding integument were thoroughly scrubbed, all hair and dirt removed, and irrigated with 1 to 2,000 bichloride solution, thoroughly curetted with a sharp Volkmann spoon, again irrigated with bichloride, and afterward sterilized salt solution. Under constant irrigation twenty-five perforations were made with a hand-awl through the outer table of the skull to the diploë. A few strips of skin were then taken from the patient's left thigh and placed over the forehead and left temporal muscle. The method of Thiersch, as perfected by McBurney, being used.

Some shock following, reaction was obtained by warmth and enemas of brandy.

April 5th.—Patient was carried twenty-four miles to Rutland, standing the journey well. Pulse, 100; temperature, 100° F.; mind clear.

April 6th.—Head was redressed; pulse, 110; temperature, 101° F.

April 8th.—Under strict antiseptic precautions and constant bichloride irrigation, fifty more perforations were made in the outer table of the skull, making in all seventy-five. Some of those previously made were also deepened, as they did not reach the diploë. A dental foot-power drill was used, which is far superior to the hand awl, as owing to its velocity no force is necessary and consequent danger to the inner table is avoided; it is much more rapid and certain. When the outer table has been perforated and the diploë reached, a feeling of lessened resistance is at once noted, and a little blood or bloody serum exudes, from injury of the vessels of the diploë. After curetting, through irrigation with bichloride and sterilized salt solution, Thiersch's grafts were taken from the thigh of an eighteen-year old sister and placed over the right temporal muscle, forehead, and occipital region. Sterilized protective and gauze wet in salt solution were placed over the skin grafts, and iodoform gauze over the perforated skull. She stood the operation well. That evening the pulse rose to 120; temperature, 103° F. The two following days the temperature fluctuated between 101 and 103½° F.

April 10th.—The dressings were removed except the protective over the grafts last placed. Most of the grafts from the first operation were destroyed. Granulations were growing through the sutures of the skull. Grafts were again taken from the sister and the remaining muscular portion covered. As the temperature during the next five days ran from 103 to 104½° F., the external dressings were changed each day.

April 15th.—Grafts were taken from the thigh of a sixteen-year old brother and placed over the occipital and frontal region where grafts had been destroyed. Three large grafts had taken over the right temporal muscle and

[1] Read before the Vermont State Medical Society, October 13, 1893.

were of a pink-rosy color and doing nicely. The pulse that evening reached 140; temperature, 105° F.

April 17th.—The bone (nine days after the last perforation) looked healthy and its returning vitality noted by a pink mottling running around the perforations and between them. In rubbing over the apertures a little blood stained serum exuded. The temperature reached 104½° F. at two different times during the twenty-four hours.

April 18th.—Grafts were again taken from the brother.

April 19th.—Eleven days after the perforations, granulations were present in nearly all the apertures, looking like little red points. The bone was rapidly regaining its normal pink color.

April 21st.—Grafts were taken from another brother. Granulations were growing very rapidly through the perforations, as were also those through the sutures. The temperature was very irregular, fluctuating between 102 and 104½° F.; pulse from 130 to 140. The patient was very weak during all this time, the mind was perfectly clear, and she had taken a large amount of nourishment and stimulants.

Cold baths did not reduce the temperature, but two and one-half grains of antifebrin, given when the temperature was highest, would reduce it, strengthen the pulse, and produce immediate sleep, while without it the patient would not sleep during the whole night.

During the first two operations, ether was administered, but after it was not, as the nerve-supply to the head being lost, no pain was experienced, even when the curette was used, except near the edges of the wound.

April 27th.—Nineteen days after the perforation, the granulations over the apertures were about the size of a split pea. Those over the sutures an inch wide and growing very rapidly; temperature began to subside, but the patient was still very weak. Grafts were again taken from the brother.

May 3d.—The temperature and pulse were steadily improving, as was also the patient's strength. Grafts were taken from a sixteen-year-old cousin.

May 7th.—One month after the perforations, only two spots about half an inch square remained of bare bone, the rest being covered by healthy granulations. The head was nearly covered by healthy growing skin-grafts; those a month old extending rapidly by marginal growth; the vitality of all was active. The patient's temperature did not run above 100° F. during the day; pulse stronger, appetite good, and strength fast increasing. One small piece of bone on the posterior part of the head, which was not perforated, exfoliated, exposing the diploë, under which were granulations.

May 10th.—The grafts on the right temporal region, thirty-two days old, did not look as healthy and began to show signs of breaking down.

May 13th.—Grafts were again taken from the cousin, the patches on the right temporal muscle had lost their vitality, some liquefying, others scaling off, leaving a smooth, pink surface underneath, which did not secrete pus. At first it was thought that this was skin, but afterward it proved to be granulating tissue. From this time the older grafts successively broke down, until, June 15th, only a few small patches remained. The head was covered by a firm, granulating tissue. The patient's temperature had been normal for a week, pulse strong and full, and she was able to walk a mile or two without fatigue.

June 15th.—After thorough curetting and irrigation, grafting was recommenced, and during the interval between that and August 15th, the head was again nearly covered by healthy growing skin. Soon after this latter date small ulcers began to appear in the older grafts, which gradually coalesced until large areas were destroyed. The skin taken from the subject, however, did not show this tendency, but steadily increased by marginal growth, was pink, elastic, and pliable, showing no tendency to ulcerate. The grafts were kept covered by lanoline and two per cent. iodoform, which stimulated them and prevented to some extent their breaking down.

August 22d.—The condition of the head was excellent, one-third of its area being covered by healthy grafts which were extending rapidly; the remaining granulating tissue was firm and healthy. The temperature and pulse had been nearly normal about three weeks, the general condition good, and she was able to walk long distances.

August 24th.—The patient was taken with diphtheria, large patches of membrane rapidly formed on the tonsils, pharynx, uvula, and even the mouth and lips. Temperature at first was 99°, afterward subnormal. On the fourth day she died.

Examination of the head after death showed the following conditions:

One third of its area covered by skin. That taken from others was brittle, and on being lifted forcibly

by forceps broke. That taken from the subject had all the characteristics of normal skin, did not break when forcibly lifted by forceps, and was pliable and velvety. The remaining granulating tissue was firm and hard. The new scalp was slightly movable over the bones. On removing it from the bone it was found to be composed of three layers intimately connected with one another. That nearest the bone had all the characteristics of normal periosteum. The second layer was firm, fibrous tissue supporting a third layer of firm granulations. The bones of the head were normal and healthy, the apertures having contracted into little foramina through which an artery and vein ran. New branches of the temporal and occipital arteries had formed running well up to the vertex.

Remarks.—In perforating the outer table of the skull a direct channel is made, through which septic infection may reach the general system. A few branches from the veins of the diploë anastomose with the dural sinuses and veins of the meninges; the larger number, however, empty directly into the general venous circulation, so general infection is more likely to occur than local cerebral manifestations. At first the apertures are absorbing, but gradually, as granulations fill their space, they become excreting. This is well illustrated by the temperature in this case, which ran very high after perforating, and did not subside until all the apertures were well filled by granulations, when it rapidly fell to nearly normal.

Ten days after perforations are made in the outer table of the skull, if the surface is rubbed, a little blood-stained serum will exude. In fourteen days small granulations appear, and in twenty-one days reach the size of a split pea; from this time the growth is very rapid, and by the fourth or fifth week will join on the edges, forming a new

scalp of granulation tissue nourished by the diploë through the perforations. This gradually contracts into a firm fibrous tissue, its inner surface making a new periosteum. The apertures contract slightly, and conduct an artery and vein of new formation. New branches of the occipital and temporal arteries gradually form. Skin removed from a second person will do well, and after two weeks extend by marginal growth. Its activity will continue for five or six weeks after graftings, when it loses its vitality, becomes brittle, and either liquefies, scales off, or small ulcers start, which extend and coalesce until large areas are destroyed. After well started it is not as soft and velvety as normal, but is paper-like and brittle; it cannot be picked up by forceps without laceration. Skin taken from the subject shows more vitality; after two weeks extends rapidly by marginal growth, it is velvety and pliable, and can be picked up by

forceps without laceration. It shows no tendency to ulcerate or break down in six weeks, but continues to extend rapidly by marginal growth. The marginal growth of skin from the sound integument is cicatricial and delicate, unless stimulated by grafts placed near it, when they stimulate each other and become normal skin.

In using small grafts make a little trough and press the graft well into the granulating tissue. When large grafts are placed, use the curette and irrigator freely, that no diseased tissue may be left under them. Do not overlap the grafts, but leave a small place for drainage, so if pus should form, it would not destroy large numbers. After grafting, the protective should be left four days or longer, unless much pus is present, as removing the protective is liable to displace and destroy the grafts. After the first dressing they should be removed every other day, or when pus accumulates. After permanently removing the protective at two weeks, an oily substance, as lanoline two per cent iodoform, will protect the skin from drying, (as the new skin has no oil glands), stimulating their growth, and preventing the gauze from sticking and detaching them. Oiled silk or rubber tissue should be placed over the dressings to prevent their drying.

As soon after the injury as the patient's strength will allow, Thiersch skin grafts should be taken from the subject, and covered over the muscular tissue, covered by the usual dressing of protective and sterilized gauze wet in salt solution. The perforated bone should be covered by an absorbent antiseptic dressing. Work first on that part of the head not subjected to pressure in the recumbent posture. In removing grafts go deep enough to reach the true skin, as the epidermis alone has not enough vitality. The surface from which grafts are removed should be at once covered with sterilized gauze, until all oozing stops. Dry sterilized protective covered with iodoform gauze, should then be applied. If after four days much pus is present, the external dressing should be removed, otherwise not disturbed for eight days, when the surface will be found healed. Irrigating or rubbing the surface just before the first dressing, or subsequently, increases exudation and retards healing.

I wish to take this opportunity of thanking the Rutland doctors, and particulatly Drs. Francisco, Caverly, and Gale, for their kind assistance and interest in this case.

OBSERVATIONS ON THE ROTARY-LATERAL CURVATURE OF THE SPINE, WITH SPECIAL REFERENCE TO ETIOLOGY AND TREATMENT.[1]

BY JACOB TESCHNER, M.D.,

NEW YORK.

THE subject of rotary-lateral curvature of the spine is one upon which there has been much written, concerning the etiology, pathology, and treatment, and upon which there has been considerable discussion. This would in a measure indicate the usually unsatisfactory or only partially satisfactory results that are derived from the treatment of these cases, and the importance of giving them proper and early attention.

I shall not, in this paper, attempt to enumerate all the ideas and views of the etiology and treatment of this condition as presented by the leading orthopedists of this country and Europe, but I shall, as briefly as possible, classify the causes which are generally accepted, and give the results of my observations, laying the greatest stress upon the most important and the most frequent causes, and submit the treatment which I have found successful.

Rotary-lateral curvature occurs most frequently, according to several observers, between the seventh and fourteenth years, only a small percentage occurring after the eighteenth year. The following figures will show the percentages occurring during the different periods in one thousand cases of Eulenberg, viz:

Years.	Per cent.
Until two	0.5
Two to three	2.1
Three to four	0.9
Four to five	1.0
Five to six	3.3
Six to seven	21.6
Seven to ten	56.4
Ten to fourteen	10.0
Fourteen to twenty	2.8

Girls are more prone to this disease than boys. Why this should be has not been definitely determined, but there is little doubt that the differences in the rapidity of growth and development during the earlier years, the organization of the nervous systems, the conditions favoring or opposing muscular development, and the habits of the sexes after school hours, are important elements in determining this fact.

I will pass over the pathological and anatomical causes, viz.: Pleurisy with adhesions, empyema, paralyses from different causes, rachitis, Pott's disease of the spine, inequalities of the length of extremities, and loss of an extremity, and consider only the following causes, viz.:

1. Hereditary tendency.

[1] Read at the Pan-American Medical Congress, September 5, 1893. Section in Surgery.

2. General temperament and the condition of the mind and nervous system.

3. Lack of development of the muscular system, and the general physical condition.

4. Habitual faulty position with superimposed weight.

1. Hereditary Tendency.—I have not been able to find any allusion citing this as a factor in the etiology of the disease, but I have frequently noticed slight curvatures and upon closer examination found decided scolioses in the mothers of girls brought to me for treatment.

I have at the present time four patients under treatment whose mothers have distinct scolioses, and one of these patients has four sisters, ranging from fifteen to twenty years of age, with slight curvatures.

I am of the opinion that if this condition of the mothers of patients were more closely investigated, that "hereditary tendency" would become generally accepted as one of the causes.

2. General Temperament, and the Condition of the Mind and Nervous Systems.—This heading is one which is apt to give rise to considerable doubt when cited as a cause, because most observers lay all their stress upon the deformity and its mechanical treatment, and to a certain extent lose sight of the general, mental, and nervous conditions of the patients.

The general temperament of most girls afflicted with rotary-lateral curvature is apathetic, indifferent, somewhat lazy, and sometimes a trifle morose. As a rule they are backward in their studies at school, and usually show a decided disinclination to romp and play after school hours, with the same vigor and enjoyment as do their companions. The facial expression is frequently a vacant stare, the lower jaw dropping and the mouth being open, giving the patient a silly appearance. This was particularly well marked in a patient sent to me for treatment by Dr. Leonard Weber, and it became more conspicuous by its absence, as noted by Dr. Weber, after the patient had been under treatment for a short time. Of course, there are all gradations between an highly intelligent and an almost idiotic countenance, but where there is a lack of intelligent expression, the face certainly changes after energetic treatment.

Under this heading, I would also call your attention to a peculiar lack of co ordinating power, or lack of muscular control with which some patients are possessed. It seems to some patients, until properly instructed, almost an impossibility to fully extend an entire extremity, either upper or lower. If, for example, a patient be instructed to hold an upper extremity abducted at a right angle to the body, palms down, and hold it rigid at all the joints and fully extended, the observer will find that if the wrist be extended, the elbow is apt to be flexed, or if the elbow be extended, the wrist will be flexed, or if both the wrist and elbow be extended, the fingers will be either flexed or hyper-extended.

This lack of co-ordination or lack of muscular control can be and is made to disappear through the muscular instruction and development which forms part of the treatment. Patients usually, when told to grasp an object firmly, a cane for instance, neither properly approximate the palm to it so as to exert an even pressure upon it, nor do they encircle it with the thumb; they hold it between the thenar and hypothenar eminences of the palmar surface of the first set of phalanges, the thumb being at a right angle to the phalanges, and the palm being hollow, thereby showing their inability to exert muscular influence in a normal or proper direction.

3. Lack of Development of the Muscular System and the General Physical Condition.—General muscular development is frequently found to be very poor or almost wanting. In most cases the trapezii, the rhomboidei, the sterno-mastoids, and deltoids especially are found almost rudimentary. The back, chest, and abdominal muscles are generally found in worse condition than the muscles of the extremities. With this state of affairs we naturally expect and find a lolling and lounging muscular habit, and a general want of muscular tonicity and precision. Patients when suspended, are rarely able to sustain their own weight.

The physical condition is as a rule not good, the patients being frequently the victims of a poor digestion accompanied by malassimilation. In girls leucorrhœa is generally present and frequently copious. In mentioning the general condition of health, I do not wish to be understood to claim that when the general system is run down, a curvature will occur, or that there are no cases of curvature in which the general health is not impaired, but I do claim that when there are tendencies to a curvature, as cited above, with the conditions as explained in the next paragraph, an impaired condition of the general health will greatly assist the rapid development of the deformity.

4. Habitual Faulty Position with Superimposed Weight.—Resting the weight of the body upon one foot while standing, or sitting more upon one buttock than upon the other, and in either position permitting the shoulders to fall forward, and the chin to approximate the chest, shows a relaxation of all the muscles which hold the spine erect in the normal condition, and permits a sagging of the upper portion of the body upon the lower, and twists the spine and trunk into a mild form of deformity, the mechanism of which was so ably demonstrated by Dr. A. B. Judson[1] at the meeting of the American Orthopedic Association, in September, 1890. This deformity passes off when a normal standing or sitting position is assumed; but when such temporary deformity occurs not only daily, but several times a day, and for protracted periods, it gradually increases and later becomes permanent and fixed, and produces the actual bony and ligamentous changes which are met with in cases of long standing.

The faulty sitting position is more frequent than the standing, as children as a rule spend about five hours in the twenty-four, sitting in school. I will therefore call your attention to the school habits of children, while sitting, and their shifting of positions to relieve the tiring of the strained groups of muscles.

Dr. A. Baginsky[2] in his admirable paper read before the "German Society for the Care of Public Health" at Berlin, in March, 1888, says: "More and more are surgeons convinced through their anatomical and physiological investigations and from their practical observations, that scolioses, the most important of all deformities of the spine, in a very large majority of cases owe their origin to the influence of school life upon the organism of the child."

This writer further shows that if we observe a class of children during the early portion of school hours, more particularly if the subject of the lesson be interesting and the weather cool, they will all sit quite erect, with their heads well poised, their chests brought forward, their feet evenly placed upon the floor (if the lower extremities are not too short to reach it), and the frontal plane of their bodies parallel to the edges of the desks in front of them. Later on, one by one, the children will permit the shoulders to drop and fall forward, the chins to approximate their chests, thereby changing the entire contours of their spines.

There is a tendency to turn the trunk to the right or left, in order to relieve one buttock of the weight of the superimposed body. Some are apt to cross the thighs, thereby producing the same effect. The frontal planes of the bodies of the children are then no longer found to be parallel to the edges of their desks.

Dr. Baginsky shows even worse positions which are assumed by children during their writing lessons, when the frontal planes of their bodies are placed at right angles to their desks.

Any change of position, no matter how slight, changes the centre of gravity, and those muscles which hold the

[1] The Rotary Element in Lateral Curvature of the Spine. A. B. Judson, M.D., N. Y. Trans-American Orthopedic Association. Vol. iii., 1890.

[2] Ueber Rückgrads-verkrummingen der Schulkinder, Deutsche Medical Zeitung, Berlin, 1888, ix., pp. 529-541.

body upright are strained as soon as the position recedes from the erect one. When one set of muscles is thoroughly tired, the child changes position to relieve the strained set of muscles, and brings those muscles which have not been taxed into play.

When children become habituated to faulty positions in sitting, they are apt to, and do, assume analogous faulty positions while standing, and when these faulty positions have been maintained for a while, decided scoliotic attitudes are seen, and, as I have stated before, even though they be temporary, they become habitual, and lay the foundation for well marked deformities.

Before taking up the treatment of scoliosis, I do not think it amiss to call general attention to the pernicious effect of long and continued school hours, without intermission for play or calisthenics, and also the improper furnishing of school houses with benches, chairs, and desks of a regulation size, without regard to the varying sizes of the pupils, and consequently without any regard for their comfort and well being. Sitting at best is tiresome, not only to children, but to everyone.

Treatment.—In every case of rotary-lateral curvature, from the mildest case to the one which appears beyond redemption, the first efforts should be directed to the prompt removal of the causes, apparent or real, of the deformity. Any shortcoming of the extremities from paralyses, inequalities, or deformities, as well as disturbances of vision, should be corrected. The child should at once be prohibited from attending school, thereby eliminating the most persistent and potent cause. The general condition of health should be carefully attended to, by the correction of any disturbances of digestion or assimilation, by frequent baths to improve the condition of the skin, by the administration of tonics, if found necessary, to improve the nervous and muscular systems, and by sufficient open air exercise. The patient should have a properly constructed chair to sit upon; the seat of the chair should incline downward from before backward, the inclination forming an angle of about eight degrees with a line parallel to the floor upon which the chair rests. The back of the chair should be properly shaped to receive the back of the patient, and it should extend at a right angle to the seat, up to the shoulders of the patient; the seat of the chair should be at such a height that the patient can rest the feet comfortably upon the floor. In a chair of this description, the patient assumes a slightly reclining position, thereby relieving all muscular strain.

The patient should be instructed to rest frequently for from five to fifteen minutes at a time by lying supine upon the floor, the lower extremities fully extended, and the upper extremities also fully extended above the head. Self-suspension by means of a Sayre apparatus twice a day should be advised, and the patient should be instructed in exercises while suspended from an horizontal bar or from rings.

I shall now consider the various degrees of scoliosis, with reference to the treatment of each degree.

1. Habitual scolioses which can be obliterated by the voluntary muscular efforts of the patients.

2. Scolioses which are not affected by muscular efforts, but which can be reduced or obliterated by suspension of the patients.

3. Scolioses which are not affected by muscular efforts, or by suspension, the deformities being fixed.

In all three forms of scoliosis nothing is of greater importance than proper, thorough, and regular gymnastic exercises, which will equally develop the entire muscular system. Various kinds of exercises have been advocated by different writers and excellent results have been claimed by them.

I wish especially to call your attention to that excellent paper of Dr. Reginald Sayre,[1] in which he minutely describes the gymnastic exercises which patients should be taught. These exercises, with slight variations, according to the requirements of individual cases, are the ones I use in cases which come to me for treatment.

1. Habitual Scolioses which can be Obliterated by the Voluntary Muscular Efforts of the Patients.—In these cases I place my entire dependence for good results upon the general directions before described, and systematic and regular gymnastic exercises. I neither consider it necessary nor wise to give support to the patient by means of any apparatus or even a corset, but I prefer to leave the muscles which are being developed and strengthened by exercises, entirely unrestrained and free.

2. Scolioses which are not Affected by Voluntary Muscular Efforts, but which can be Reduced or Obliterated by Suspension of the Patients.—In this clase of cases I adopt the same course and plan of treatment as in the first class of cases, but in addition I find it necessary and beneficial to apply well-fitting, light, and well cemented plaster of Paris corsets, while the patients are suspended in a Sayre apparatus, and to permit the patients to wear them, if the deformities are obliterated when the first corsets are applied, until they have improved sufficiently to enable them to correct their deformities through their own muscular efforts. They are then treated as patients of the first class. In those cases in which the deformities are only reduced but not obliterated by suspension, as the patients improve under treatment new corsets are applied from time to time, until at last the deformities can be entirely obliterated by suspension. These also become patients of the first class.

3. Scolioses which are not Affected by Voluntary Muscular Efforts, or by Suspension, the Deformities being Fixed.—The treatment of this class is the same as that in the foregoing class, but other means must be resorted to to reduce the fixed deformities of the ribs and spine. I have found the forcible daily twisting of the spine and compression of the ribs, of considerable value in reducing the fixed deformities, and I have within the past two weeks begun the use of an apparatus used by Dr. Albert Hoffa, of Wurzburg. This apparatus is described in the *Zeitschrift für Orthopædischer Chirurgie*, 1891. Although I am not in a position to claim any results or benefit from the use of the apparatus, I judge from appearances and from the combined effect of suspension, fixation of the pelvis, twisting of the spine, and pressure upon the scoliotic eminence, that it will prove to be a powerful adjunct to the more successful treatment of old cases of fixed scolioses.

It will give me great pleasure to report the results of cases treated in this manner, whether successful or otherwise.

134 East Sixty-first Street.

[1] New York Medical Journal, 1888, vol. xlviii., pp. 533-538.

The Use of Cocaine.—1. Amount of cocaine used must be in proportion to extent of surface it is desired to anæsthetize. In no case should the quantity exceed one grain and three-quarters. 2. Cocaine should never be used in cases of heart disease, pulmonary disease, or in persons of highly nervous temperament. 3. In injecting cocaine, the intradermic method is preferable to hypodermic. By injecting into, not under, mucous membrane or skin, the risk of entering a blood-vessel is avoided. 4. During injection the patient should always be in a recumbent position; in operations upon the nose and throat the head should not be raised until anæsthesia is complete. 5. It is of great importance that cocaine should be pure, since its combinations with certain other alkaloids result in poisonous compounds.—*Brooklyn Medical Journal.*

To Quench Thirst After Abdominal Operations.—Water alone will do it, but if given by the mouth it is often vomited, or else excites intestinal activity, which, for some hours at least, must be carefully avoided. Hence we may inject per rectum half a pint of warm water every two hours during wakefulness. This will generally permanently relieve the thirst in twelve hours. —Dr. C. W. Cathcart.

DEPRESSED FRACTURES OF THE SKULL.[1]

A Clinical Study, with a Report of Forty Operative Cases at Chambers Street Hospital in the Service of Dr. Lewis A. Stimson.

By CARTER S. COLE, M.D.,

NEW YORK.

If an apology be needed, Mr. President and gentlemen, for calling your attention to a subject by no means new, and one to which a number of recent valuable contributions have been made, it is hoped that it will be found in the practical possibilities which it is the effort of this paper to propose.

In the eyes of many, statistics prove nothing; and yet, there are not a few who accept nothing as proved without them. While it is true that the number of cases here cited is, probably, small, the fact obtains that the same is sufficiently large to emphasize the validity of the arguments advanced; and I must here add my indebtedness for the use of these cases to Dr. Lewis A. Stimson, the Attending Surgeon to Chambers Street Hospital, in which institution all of the cases were observed.

In a comparatively fair acquaintance with practitioners in general, I find such a radical difference in the management of these cases—and it may be added such a material difference in the results—from the routine practice at the hospital mentioned, that it seems almost a duty to present to the profession the methods there employed. May it not be said that the average practitioner views a compound depressed fracture of the skull with such consternation and irresolution that he may almost be pardoned for inaction, if not for the results attending such a course. And yet, in the light of these cases, it will hardly be possible to suppose that one could hesitate as to the necessity of an immediate and accurate determination of the conditions present, and then, the adoption of prompt remedial measures.

It is not with regret that I am unable to recite a number of cases in which to neglect can be fairly attributed meningitis of one variety or another, cerebritis, local or general, epilepsy, atrophies, paralyses, and death. That such has often been the case we know too well; let that suffice.

Independent of the eight cases in which I, personally, operated, it has been my privilege to be present, or assist, at twelve of the other cases, as well as to follow them in their subsequent course; and whatever conclusions I may have to draw are from a personal experience, it is fair to say, with half of the cases, not from an abstract study of the histories.

Let me say first of all that Dr. Stimson insists on differentiating the "bursting" fractures from the circumscribed fractures; those due to multiple forces from those due to individual forces; the long linear fractures without or with inconsiderable depression in the one set of cases, with or without lines of fracture running into the base in which no operation is of value, from the circumscribed cases, especially with a wound present, in which we usually find that an operation for drainage and the relief of the depression and compression is entirely satisfactory.

That considerable depression may exist with no symptoms and with little prospect of immediate danger we know full well; and that a by no means inconsiderable compression may obtain under similar conditions is also well established; but in view of the hemorrhages from meningeal lesions, of the lacerations of the meninges themselves, of the injury almost sure to follow if not already present to the cerebral tissues in such cases, we cannot see how an operation could intelligently be denied.

In regard to the terms depression and compression we thoroughly agree with Dr. Phelps, who says: "If they be discarded, the form of injury the patient has suffered in a given case—as laceration, general contusion or fracture with hemorrhage—is more likely to be accurately determined than if attention be directed solely to a symptomatic condition that may not clearly exist."

After the original injury, if a wound be present, sepsis is our great foe; without a wound, softening of the clot or brain or both with or without meningitis are in the line of the consequences most to be feared. (Case reported by Dr. Wells in May, 1891, New York Medical Record.)

Apart from book symptoms how can we diagnosticate a fracture of the vault of the skull, with or without depression? Before attempting an answer, let us clear the field in a measure. First of all, the fine distinctions between compression and concussion appear to be simple in print; in practice the differentiation is by no means easy; indeed, at least in traumatic cases, though we may often have concussion without compression, the reverse seldom obtains. Who can say in severe cases where one begins and the other ends? I am much inclined to believe with Dr. Phelps that, "if they be discarded, the form of injury the patient has suffered in a given case—as laceration, general contusion, or fracture with hemorrhage—is more likely to be accurately determined than if attention be directed solely to a symptomatic condition that may not clearly exist."

As the result of trauma, it sometimes happens that without a fracture, a limited hemorrhage occurs, between the periosteum and bone, between the membranes of the brain and periosteum, or beneath the dura; but such cases are extremely unusual. Hemorrhage by contre-coup is more frequent, and is more serious. In any event, did compression from hemorrhage or depression obtain, operative interference would be indicated. We must not overlook the fact, however rarely it happens, that the inner table may be fractured and depressed, without a fracture or depression of the outer, nor the reverse, which more frequently happens.

Again, we must remember that, in many cases, absolutely no symptoms of compression are present immediately after the receipt of the injury, even where the depression and the compression are considerable; and in no instance are we justified in waiting for symptoms where we know that depression obtains, and a wound is present.

To come now more directly to the answer to our question, the nature of the injury is an important aid in reaching a general conclusion and presumptive diagnosis, apart from objective symptoms, *e.g.*, it is seldom that a child does not sustain a depressed fracture when kicked in the head by a horse; a brick falling a considerable distance, a sharp pointed pile, a bar of iron, etc. etc., are quite apt to cause such a lesion. A heavy person falling so as to strike the head on a sharp object (*e.g.*, Cases X. and XVIII.) is apt to sustain a depression, and if the fall be backward down stairs, a fracture of the base is quite likely. An axe or a hatchet in skilful hands is conducive to such lesions, as are beer bottles and edged bars. In short, a careful inquiry in regard to every detail of the accident may repay us richly. Again, where the depression is near the speech centre, the *diagnosis* can be, and indeed was, made in two cases (XI., XXII.), by pressing on the injured part, and making the patient cry out from deep coma. When, as is often the case, a large hæmatoma obtains, the examining finger may displace the clot first at one spot, then at another, until the whole space has been carefully examined for overlapping edges of bone; and yet, it is only fair to say that the rim of clotted blood will often deceive the closest observer. But, if there existed not the first symptoms of depression, and the character of the injury justified us in thinking that such was probable; or, to put it another way, if we were seriously in doubt as to the existence or non-existence of a depressed fracture, with compression either from bone or hemorrhage, with coexisting meningeal lesions, our duty would be to make an incision through the periosteum, over the suspected part, and carefully examine with the best of all probes, the finger. If a

[1] Read at the twenty-fourth annual meeting of the Medical Association of Virginia held at Charlottesville, October 31, 1893.

wound already exists, it can, with no impropriety, be enlarged, if we are unable to decide as to the condition of affairs. A probe will smoothly glide over *unruptured* periosteum where there has been even a considerable depression beneath, and we should keep this possibility in mind, and make sure of getting down to the bone itself. So much in a general way for what would lead us to suspect a depression, apart from symptoms, always keeping in mind the fact that a considerable depression may, and often does, exist with absolutely no symptoms. We will not dwell on coma, convulsions, and other objective symptoms, so that we may insist the more strongly on an absolute determination in cases of doubt by an incision, if necessary. What are we to do in the presence of such an injury? Our invariable rule at the Hospital is, symptoms or no symptoms, in the cases of circumscribed lesions, to operate, relieve the depression, and *without* delay. Several cases, it will be seen, were operated on with no anæsthetic, one with cocaine, but the large majority with ether. In cases of profound coma ether may be dispensed with, although, even in these, it often saves trouble after the compression has been relieved. First, then, settle in our own minds the existence of a depressed fracture, by making an incision, if necessary; next, be prepared to go ahead and relieve it. The technique and appliances are simple. The hair is shaved for several inches over and near the seat of depression, the scalp thoroughly scrubbed with soap and water and a brush, the operator's hands thoroughly scrubbed before and after the cleansing of the scalp, and both disinfected or cleansed and kept clean. A bichloride towel is wrapped around the head. A chisel—almost any small hard-steel chisel will do—a mallet, an elevator, a pair of thumb forceps, one or two artery clamps, needles, and a scalpel constitute all the necessary instruments, and to them we should add catgut, thoroughly sterilized, for sutures and ligatures, and antiseptic dressings. The incision should be sufficient to satisfy the operator that no depression exists beyond the parts readily examined. [This is mentioned because a fissure will sometimes run along under the scalp and be depressed at the termination. This was the case several times in the reported cases.] In order to elevate the depressed bone, we have never seen but one case (X.) in which it seemed especially difficult to attain the result by the use of the chisel; in which, to put it more strongly, the trephine seemed justifiable. As a matter of fact, the latter instrument should be reserved for cases in which the outer table of the skull has not been fractured, but in which it is desirable to inspect the dura or brain. The secret of so loosening the pieces as to elevate without difficulty consists in removing with the chisel the over-lapping edge—generally $\frac{1}{16}$ to $\frac{1}{8}$ inch—so as to allow the border of the depressed edge, when elevated, to pass by the border of the bone which has overhung it. Sometimes a little triangular piece of bone is detached completely, and is easily removed, and the elevator readily introduced; but it is seldom possible to completely elevate without chiselling away the edge overhanging. No loose bone is removed, that is, none of the fragments, unless completely detached, and care should be taken when elevating not to detach pieces already partially free. A small piece can, without fear, be removed; but, if a piece of considerable size is completely detached, it is better to try to get an attachment for it by leaving it, possibly where one side has a serrated edge, trying to force the edges together. The slightest periosteal or dural attachment is invaluable, and should be inviolable. The rongeur is occasionally useful, but seldom necessary.

Any laceration of the dura and of the brain substance naturally adds a complication to the prognosis, but in cases promptly and properly attended, this seems not to have changed the generally excellent result. Cases complicated by extensive laceration of brain substance, or by a line or lines of fracture extending into the base, are almost uniformly fatal. Suicidal gunshot wounds of the skull are almost invariably fatal, if they enter the cranial cavity. In one case we have seen the ball escape in the roof of the mouth, and in another case be buried in the labyrinth of the ear, without producing a fatal result; but in neither case did it enter the cranial cavity.

To complete the technique, if the vessels cannot be readily caught, the cavity can be well packed with gauze and the edges of the wound sutured after twenty-four or forty-eight hours, or partly sutured at the time, and the gauze removed after twenty-four hours, and then the sutures completed or not according to the amount of discharge. Over all put a full dressing and good firm bandage. A drainage-tube will seldom be necessary, and if used should not come in contact with the brain itself. The sinuses sometimes give trouble from hemorrhage, but gauze packing and good compression generally suffice to control it.

In ordinary cases when a light gauze drain is used—and we are not prepared to commend its omission—the case is redressed in four days, the drain left out and then not redressed for six days unless the dressings become loose. After this a very simple dressing suffices and the patient gets about, going home in two or three days more. In private practice this period of confinement to bed would hardly be less than a fortnight and to the house another week.

A direct examination of the cases reported shows that six were fatal, and of these all but one had a fracture of the base, and this exception had an extensive fracture with considerable loss of bone substance (a loss increased by the use of the trephine) followed by a large hernia cerebri. My own fatal case was *in extremis* when admitted. In none of the cases did the operation for relief of the depression have any relation to the fatal termination, and in a fair number of the favorable cases serious danger or death was inevitable without an operation.

The trephine was only used in Cases X., an impacted foreign body, XV., for no reason apparently, XXIII., a linear fracture with suspected blood-clot and compression, and XL., where probably a conoidal piece had been driven in by an ice-pick; but in Cases VIII. and XVIII. the chisel was sufficient; indeed, it is but right to protest here again against the use of the trephine for depression, unless it is impossible to elevate with the chisel and elevator.

In fifteen cases the symptoms were noted as being absent, and it is not unlikely that such was true of several others. In Case XXXIII. the symptoms of compression were present, but no compression was found. The ages varied from two and one half to fifty-seven years.

Anæsthesia was not used in six cases; cocaine was used in one case and ether was used in the remainder.

Resumé. *Fatal Cases.*—Operator, Harris. Case VII., aged twenty-one. Fracture base. Fell four stories. Probable laceration brain. Large piece of bone removed.

Operator, Stimson. Case XIV., aged twenty. Fracture base.

Operator, Wilkin. Case XV., aged twenty. Extensive fracture and loss of bone substance; hernia cerebri.

Operator, Cole. Case XIX., aged fifty-seven. Fracture base; laceration brain; intra-cranial hemorrhage; rapidly fatal.

Operator, Crofton. Case XXIX., aged twenty-eight. Fracture base.

Operator, Manning. Case XXXIX., aged forty-eight. Probably fractured into base and compressed by blood-clot.

Trephine.—Operator, Stimson. Case X., aged fifty. Impacted foreign body.

Operator, Wilkin. Case XV., aged twenty. Extensive depression; but could have been relieved by chisel elevator with less loss of bone.

Operator, Hancock. Case XXXIII. Linear fracture; supposed clot; none found.

Operator, Manning. Case XL., aged twenty-four. Probably conoidal piece depressed; but compare VIII. and XVIII., where the chisel was efficient.

Symptoms.—Noted as entirely absent in fifteen cases,

thirty-seven and one-half per cent. Present but no compression found in one case (XXXIII.).

Operators, Kimball, I.; Harris, II., III., IV., V., VI., VII., VIII.; Southworth, IX.; Stimson, X., XI., XIV.; Harvey, XII., XIII., XXI.; Wilkin, XV.; Cole, XVI., XVII., XVIII., XIX., XX., XXI., XXII., XXXII.; Hancock, XXIII., XXIV., XXXIII.; Wells, XXV., XXVI., XXVII., XXVIII.; Crofton, XXIX., XXXIV., XXXV.; Proctor, XXX.; Van Rensselaer, XXXVI., XXXVII., XXXVIII.; Manning, XXXIX., XV.

The fact that the same general result obtained for thirteen operators would indicate the general applicability of the practice. Of the whole number, if we exclude of the fatal cases those inevitably so under any form of treatment, we have a single fatal case (XV.), and it is hardly fair to say that this was the result of the operation, though it would certainly have been much more rapidly so without operation. On the other hand, of the thirty-four remaining cases, at least one-fourth would in all probability have proved fatal without operative measures, and one half, if not a much larger proportion, would have been followed by disastrous secondary troubles.

Of the cases reported, all but one were depressed, and in this case the symptoms of compression were present.

I have purposely omitted the linear fractures without depression, in which our rule was to explore and then treat as a simple scalp wound; of these, not a single one gave any after trouble. Likewise, I have not reported the suicidal penetrating pistol-shot wounds of the vault, every one of which has proved rapidly fatal, with or without operative measures.

If I have demonstrated the value of an immediate and accurate determination, by an incision, if necessary, of the variety and extent of the lesion in injuries to the vault of the cranium; of the necessity for their immediate relief by the use of the chisel and elevator; of the facility of the steps and of the easy technique of such procedures, I shall, at least, hope that my efforts have not been misspent.

Depressed Fractures of the Skull From August 23, 1888 to January 1, 1892.—Case I.—Operator, Kimball. Josephine D——, aged eight. Admitted August 23, 1888. Lacerated wound three fourths inch long, just below right parietal eminence. Triangular piece depressed; size finger-nail. No symptoms. Operation, August 24th.—Ether. Depressed bone, one-fourth inch, removed. Chisel. Several small pieces removed. Interrupted sutures Catgut drain. September 2d.—Redressed; drain removed. September 13th.—Cured.

Case II.—Operator, Harris. Richard O'M——, aged thirty; married; Ireland; longshoreman. Admitted October 5, 1888. Struck with iron in right parietal frontal region. Semi conscious, slight but increasing paralysis left arm, and convulsive movements left side of face; speech thick and indistinct. Respiration, pupils, pulse, normal. Ether. Depression nearly one inch; four pieces bone, pyramidal. Depressed area bounded anteriorly by coronal suture; inferiorly, one-fourth inch above parietal suture. Lower border, two and one half inches; superior border convex and parallel to temporal ridge and at highest point one-half inch above. Curves backward and downward and joins lower line at a point about two and one-half inches above, and one and one-half inch posteriorly to, external auditory meatus. Distance between inside points of superior and inferior borders is about two and three-fourths inches. Rongeur; inner table more extensively fractured than outer; small pieces of bones removed; rubber drain. Iodoform and bichloride dressing. Pulse quick and strong. Respiration bad. October 9th.—Redressed; drain removed. October 16th.—Redressed. October 20th.—Put in small drain. October 28th.—Drain removed. November 5th.—Cured.

Case III.—Operator, Harris. Patrick McA——, aged twenty-five; single; 'longshoreman. Admitted October 27, 1888. Walked in. Struck with water pitcher night before. Lacerated wound about one inch front of fronto parietal suture, two inches to left median line. Depression one-fourth inch. Operation, ether (after twelve hours); washed, shaved, etc.; chisel; elevator. Dura uninjured; small pieces removed; rest elevated; rubber drain. October 29th.—Tube removed; horsehair inserted. November 4th.—Redressed; drain shortened. November 8th.—Drain shortened. November 9th.—Drain removed. November 10th.—Cured.

Case IV.—Operator, Harris. John S——, aged thirty-four; single; Ireland; 'longshoreman. Walked in to Dispensary November 21, 1888. Struck by block one and a half hour before. Lacerated wound in anterior superior parietal region. Circular depressed fracture, cone-shaped. Operation: No anæsthesia; chisel, rongeur, elevator. Loose and depressed fragments removed; dura uninjured; catgut drain. November 23d.—Redressed. November 30th.—Drain removed. December 3d.—Cured.

Case V.—Operator, Harris. Cornelius G——, aged forty-two; single; Germany; clerk. Admitted November 27, 1888. Brought in; fell down stone steps; small lacerated wound on post-inferior part of right parietal bone. November 28th, ether. Elliptical depression one and one-half inches; anterior part one inch deep; chisel, elevator; and large piece of bone of outer table removed. Diploë bled extensively; internal table removed over corresponding area; dura uninjured; rubber tube; periosteum and scalp separately sutured. November 30th.—Redressed; removed tube. December 3d.—Redressed. December 8th.—Cured.

Case VI.—Operator, Harris. Nicholas P——, aged twenty six; single; Italy. Admitted January 2, 1889. Shot with 38 calibre pistol, one inch above orbital, one and three quarter inch from median line; second wound one and a half inch further up. Operation: Cocaine. Piece one inch long, three-quarters inch at base, removed; dura lacerated; silk sutures: considerable hemorrhage; compression. January 5th.—Redressed; rubber drain down to dura. January 10th.—Redressed; drain removed. January 18th.—Discharged, cured.

Case VII.—Operator, Harris. Harry T——, aged twenty-one; single; United States; painter. Brought in January 18, 1889, 6.25 P.M. Fell four stories through elevator shaft. Hæmatoma over posterior portion of right parietal region. Superficial scalp wound. No fracture can be made out; perfectly conscious. Head shaved and dressed bichloride. May 9th, 10 A.M.—Patient slightly delirious, but pupils are regular, of normal size. 3 P.M., exploratory incision because of the delirium recurring at intervals; cocaine. Large area depressed bone involving post-superior part of right parietal bone, extending one-half inch beyond suture on left; below bounded by lambdoidal suture two and one-half inches long vertically. Two pieces, the upper one inch square, loose, and removed, lower one elevated and left. Thick clot between skull and dura. Deep parts affixed with catgut, and another line used for scalp; rubber drain. January 19th.—Plaster Paris bandages to keep on dressings at night because of delirium. January 20th.—Noisy and delirious, and on January 23d, at 4.20 A.M., died after violent delirium.

Necropsy.—Fracture continued into base was depressed one-fourth inch, and there was an effusion of blood externally.

Case VIII.—Operator, Harris. James M——, aged twenty, single; United States; clerk. Admitted March 19, 1889. Injured February 18, 1889. Conical, one-half inch depressed fracture; one and a half inch in diameter. Post-superior part left parietal bone near longitudinal sinus. Ether; chisel. Dura uninjured; gauze drain; pieces removed. March 25th.—Redressed; considerable pus; no infection. March 29th.—Redressed. April 2d.—Went home to return every two or three days. May 4th.—Well.

Case IX.—Operator, Southworth. John S——, aged forty-five; single; Ireland; steamboatman. Admitted April 15, 1889, 12.15 A.M. Walked in. No anæsthesia.

Supra-orbital arch depressed; small fragment removed. April 16th.—Temperature, 101.5° F.; no chill. April 17th.—Well defined erysipelas. April 18th.—Sent to Bellevue.

Case X.—Operator, Stimson. John S——, aged fifty; widower; United States; watchman. Admitted April 17, 1889. Injured April 11, 1889. Fell striking on end of paint brush; ambulance. Punctured wound, one-fourth inch in diameter above superior curved line of occiput, three-quarters inch to right of median line. Ether; wound plugged by wood; trephine (wood five eighths inch long, five sixteenths diameter). April 18th.—Complete paralysis left arm; partial aphasia. April 23rd.—Wound situated five and one-half inches behind bregma; one and three-fourths inches above exterior occipital protuberance; one and one-half inches right median line. May 29th.—Transferred to New York Hospital; improved.

Case XI.—Operator, Stimson. Celia M——, aged six; United States. Admitted July 14, 1889. Comminuted depressed fracture, lacerated membranes and protrusion brain; coma; left side paralysis. No anæsthesia; chisel; sutures at either end; centre packed gauze. July 22d.—Wound gapes; some hernia cerebri; pressure. July 23d.—Fungus cerebri scraped away; suture over it. July 31st.—Temperature, 103° F. August 1st.—Dressings removed; no pus found. August 23d.—Fungus almost gone; wound granulating. September 8th.—Has been dressed twice a week. Discharged; cured.

Case XII.—Operator, Harvey. Lizzie M——, aged five; Italy. Admitted July 23, 1889. Depressed fracture; ether; chisel; elevator; drainage-tubes; sutures. July 27th.—Primary union; tubes shortened. July 30th.—Tubes removed. August 3d.—Wound healed. Patient discharged.

Case XIII.—Operator, Harvey. Lazarus B——, aged four; England. Admitted August 6, 1889. Depressed fracture; ether; incision; chisel; elevator; sutures; drain. August 13th.—Primary union throughout. August 23d.—Discharged; cured.

Case XIV.—Operator, Stimson. George E——, aged twenty. Admitted August 21.—Comminuted depressed fracture with fracture base; ether; chisel; elevator; etc. August 22d.—Very restless. Temperature, 102° F; pulse, 120. 23d.—Died 3.05 A.M.

Case XV.—Operator, Wilkin. William F——, aged 20. Admitted September 6, 1892. Comminuted, depressed fracture (extensive); lacerated dura; ether; trephine; elevator. September 9th.—Purulent discharge. September 13th.—Hernia cerebri. September 15th.—Abscess beneath dura; incised and drained. September 16th.—Large hernia cerebri. September 18th.—Hernia degenerating. September 28th.—Applied nitric acid and straps for pressure. October 3d.—Rubber ligature to hernia. October 6th.—Hernia reduced; silk sutures to wound. October 8th.—Patient apathetic; Temperature, 104° F; sutures removed. October 11th.—Abscess in brain tissue opened; unconscious. October 12th—Died 8 A.M.

Case XVI.—Operator, Cole. James H——, aged twenty-four. Admitted January 25, 1890. Compound, depressed fracture; ether; chisel; elevator; drain-tubes. January 26th.—Facial neuralgia opposite side. January 31st.—Redressed; tubes removed. February 5th.—Discharged; cured.

Case XVII.—Operator, Cole. James T——, aged thirty-nine. Admitted February 10, 1890. No anæsthesia; chisel; elevator; tubes. February 15th.—Redressed; immediate union; tube shortened. February 17th.—Tube removed. February 20th.—Cured.

Case XVIII.—Operator, Cole. Thomas F——, aged thirty-nine. Admitted February 16, 1890. Comminuted, depressed fracture; phthisis pulmonalis. Operation February 17th.—Ether; chisel; thumb forceps and tenaculum. Conoidal piece removed; excessive hemorrhage (sinus); open dressing (packed). February 18th.—Hemorrhage arrested; catgut sutures; tube drain. February 22d.—Tube removed. February 25th.—Suture at site of tube. March 24th.—Small sliver bone removed. April 24th.—Still exfoliating slightly. May 24th.—About well.

Case XIX.—Operator, Cole. John McG——, aged fifty-seven. Comminuted depressed fracture; fracture base; lacerated brain, intracranial hemorrhage. No anæsthesia; patient *in extremis;* died in an hour or so.

Case XX.—Operator, Cole. Michael G——, aged ten. Depressed fracture, March 25, 1890. Ether; incision; chisel; elevation; drainage. April 20th.—Discharged; cured.

Case XXI.—Operator, Cole. John C——, aged eighteen. Admitted May 3, 1890. Compound comminuted depressed fracture skull; ether; chisel; removal detached bone; drain. May 16th.—Discharged; cured.

Case XXII.—Operator, Cole. Norah K——, aged five. Admitted May 18, 1890. Operation May 19th.—Ether; compound comminuted depressed fracture; chisel; elevator. May 25th—Drain removed. May 27th.—Redressed. May 30th.—Cured.

Case XXIII.—Operator, Hancock. Henry W——, aged four. Admitted June 8, 1890. Ether; chisel; elevator; redressed every four days. June 20th.—Discharged; cured.

Case XXIV.—Operator, Hancock. Hugh F——, aged fifty-two. Admitted July 21, 1890. Compound depressed fracture; ether; elevation; drain. Discharged; cured, August 11, 1890.

Case XXV.—Operator, Wells. August O——, aged forty-six. Admitted August 17, 1890. Compound depressed fracture; ether; elevation; drain. Redressed every two or three days. Discharged; cured.

Case XXVI.—Operator, Wells. James Y——. Admitted August 17, 1890. Compound depressed fracture; laceration dura and brain; ether; chisel; elevation; removal of bone. Cured.

Case XXVII.—Operator, Wells. Joseph P——, aged thirteen. Admitted October 15, 1890. Compound comminuted depressed fracture; punctured; ether; elevation and removal depressed bone. October 29th.—Discharged; cured.

Case XXVIII.—Operator, Wells. Herbert H——, aged fourteen. Admitted October 16, 1890. Compound depressed (punctured) and not impacted; three hours; ether; removal bone; drainage fracture. October 30th.—Discharged; cured.

Case XXIX.—Operator, Crofton. Andrew P——, aged twenty-eight. Admitted November 27, 1890. Died same night. Compound depressed fracture and fracture base; elevation and drainage; ether.

Case XXX.—Operator, Proctor. David A——, aged two and a half. Admitted July 7, 1889. Compound depressed fracture. Patient vomited, was drowsy, etc.; ether; operation sixteen hours later. Line of fracture forward and upward from posterior inferior angle of right parietal bone; trephine; incision; chisel; elevation; abundant hæmorrhage; iodoform gauze packing. July 11th.—Redressed. August 9th.—Discharged; cured.

Case XXXI.—Operator, Harvey. William H——, aged thirty-two. Admitted September 10, 1889. Kicked by horse; perfectly conscious; compound depressed bone one and a half by one-half inch over right parietal bone. Operation seven hours later. Ether; incision; chisel; small piece bone removed; catgut sutures; tube. September 4th.—Redressed. October 14th.—Discharged; cured.

Case XXXII.—Operator, Cole. James D——, aged fifteen. May 13, 1890. Struck by iron shutter that had fallen four stories. Conscious. Compound comminuted depressed fracture skull, one inch above the middle of the supra-orbital ridge. Loose fragments removed; no anæsthesia; gauze drain; catgut sutures. Sent to New York Hospital.

Case XXXIII.—Operator, Hancock. Charles S——,

admitted June 9, 1890. Fell fifteen feet; comatose; paralysis right side body; chronic convulsions left side of face and body; linear fracture about lambdoidal suture. No depression; trephine; no clot, and no hemorrhage. June 23d.—Discharged; cured.

Case XXXIV.—Operator, Crofton. Bernard A——, aged thirty. Admitted April 1, 1891. Compound depressed fracture. Considerable shock from fall of thirty-five feet; conscious; ether (three hours later); incision; chisel; elevator. April 4th.—Redressed. April 20th.—Cured.

Case XXXV. Operator, Crofton. Gussie M——, aged five. Admitted April 14, 1891, 7:30 P.M. Came in. Absolutely no symptoms; lacerated wound and depressed fracture. Ether; chisel; elevator. April 24th.—Redressed first time. April 29th.—Discharged; cured Small pieces bone removed; inner table hard to elevate; no drainage; sterilized milk.

Case XXXVI.—Operator, Van Rensselaer. Reuquall S——, aged seven. Admitted June 20th, 1891, 10 P.M. Fell two stories. Depressed fracture; conscious and talkative; large hæmatoma frontus; unconscious during night. Ether; incision; chisel; elevator; removal elevated particle inner table; catgut and gauze drain. July 5th.—Cured.

Case XXXVII. Operator, Van Rennselaer. Miller B——, aged thirty-two. Admitted August 22, 1891. Collapsed building, 74 Park place. Conscious. Compound depressed fracture. Ether; incision; chisel; small fragments removed; elevator; iodoform gauze; silk sutures. September 3d.—Practically cured.

Case XXXVIII.—Operator, Van Rensselaer. Joseph P——, aged twenty-four. Admitted August 27, 1891. Struck by shovel. Compound depressed fracture; semi-comatose. Ether; incision; chisel; elevator; profuse hemorrhage; iodoform gauze drain. September 5th.—Redressed. September 8th.—Discharged; cured, practically.

Case XXXIX.—Operator, Manning.—John W——, aged forty eight. Admitted October 29, 1891. Compound depressed fracture of skull in temporal region. Ether; incision; chisel; elevator. Removal piece size ten-cent piece. Died 2:30 A.M., October 30, 1891.

Case XL.—Operator, Manning. Daniel S——, aged twenty four. Admitted December 2, 1891. Walked in. Struck by ice pick. Ether; trephine. Removal piece of bone; iodoform gauze packing. December 5th.—Redressed. December 8th.—Redressed, and thereafter every third day. December 18th.—Discharged; cured.

Mushroom Poisoning (the Coprinus Comatus).—Dr. Harvey B. Bashore writes: "As cases of mushroom poisoning have been recently reported in New York, I beg to offer the description of at least one fungus which is not poisonous, and which I have lately found in this vicinity—*i.e.*, the coprinus comatus or maned agaric. The description, somewhat modified, is that given by Dr. Taylor, of the United States Department of Agriculture: 'The cap is white, and at first cylindrical, two to four inches long and one to one and a half inches in diameter, and somewhat scaly; at the culmination of growth, the lower part of the cap expands and ultimately becomes bell-shaped, and the gills, which at first are white and then pink, finally turn black and soon melt into an inky fluid; on the stem, which is white and hollow, there is a ring, at first movable, later disappearing. This fungus grows in meadows, and should be gathered when the gills show a pink margin.' The coprinus comatus decays very rapidly, and for this reason is rarely seen in the markets; its nutrient value, however, is high, for it is said to contain twenty-five per cent. of proteids and two to three per cent. of fats; its characteristics are so marked and distinctive that an error hardly seems possible, and as it grows, in some instances at least, in the greatest abundance, it is a valuable addition to our food supply."

BLOODLESS AMPUTATION AT THE HIP-JOINT BY AN OLD METHOD.[1]

By W. H. BUECHNER, M.D.,

YOUNGSTOWN, OHIO.

Amputation at the hip joint has long been recognized as the greatest traumatic encroachment which the human organism can withstand. Under the improved methods of to-day the mortality is about fifty five or sixty per cent., while in days gone by it was estimated at from seventy to ninety per cent.

The fact that almost fifty methods of performing this operation have been devised would seem to indicate that no one of them was satisfactory, and the eagerness with which the methods of Wyeth and Senn have been taken up by the profession, gives additional testimony in this direction. This, however, I do not consider the case. It is a repetition of the old story of vaginal specula and obstetrical forceps. Everyone makes some modification and calls it by his own name.

In our haste to adopt the new methods of Wyeth and Senn we have completely lost sight of the old ones, of which they are simply slight modifications. I refer to the method of Volkmann, Esmarch, or Jordan (as it is variously named) and to that of Trendelenburg.

The Volkmann operation, of which Wyeth's is a modification, is performed as follows: The leg is rendered blood-empty by elevation or elastic compression and an Esmarch tourniquet is applied as close to Poupart's ligament as possible. Slipping of the tourniquet may be prevented by applying it over two or three short pieces of bandage, which are then held by an assistant. A simple amputation of the thigh is made by the circular or mixed method, at a point indicated by the condition of the soft parts. After the vessels have been secured, as in an ordinary thigh amputation, the tourniquet is removed. When all hemorrhage has been checked, an incision, similar to Langenbeck's incision for resection of the hip, is made from a point two inches above the great trochanter along the shaft of the femur to the amputation wound. If the mixed method of amputation has been employed, this incision should meet the amputation wound at the external angle of the flaps. The hemorrhage from this incision, which should divide all structures down to the bone, is very slight. The few small vessels which spring are readily controlled by pressure forceps. After this has been done the bone is seized with lion jawed forceps, disarticulated, and dissected out. This dissection is best done by means of blunt instruments assisted by the knife where necessary, the instruments being kept in contact with the bone. If thought advisable the bone may be removed subperiostially. The hemorrhage following this stage of the operation is practically nothing. The operation thus performed is almost as simple as an ordinary thigh amputation.

June 28th.—I had occasion to amputate at the hip-joint in a case of osteo-myelitis of the femur. I employed the above method with the most eminent satisfaction. My patient, a man thirty-eight years old, was very much emaciated and reduced in strength, he dared not lose much blood, neither did he. The operation was as bloodless as any amputation could be. The case made an uninterrupted recovery and was discharged in seven weeks.

As may be seen, Wyeth's method is remarkably like this one which has been in use for years. Wyeth employs two pins to prevent the slipping of the Esmarch tube—an unnecessary precaution in the majority of cases—and does not make the longitudinal incision which greatly facilitates disarticulation and the subsequent removal of the bone. Wyeth, however, is not the first to employ the latter modification. Koenig speaks of it in his work on surgery, but prefers the longitudinal incision, as it affords better drainage, and without it the skin covering the great trochanter is left very thin after the

[1] Read before the Mahoning County Medical Society, November 22, 1893.

enucleation of the bone. With these slight differences the old operation of Volkmann and the new one of Wyeth are identical.

I speak of this as Volkmann's method because the German authorities ascribe it to him. In England it is known as Furneaux Jordan's. It is not his. On page 303 of the second edition of "Surgical Enquiries," Jordan himself says "First enucleate the bone, then cut through the limb at any desired spot." The difference between this and preliminary amputation will readily be seen.

Senn's method bears a striking similarity to one devised by Trendelenburg, and published several years ago. They are identical in principle and the difference in their execution is slight indeed. Trendelenburg begins with a typical Langenbeck resection—removing the head and neck of the femur to gain room. From the resection wound he bores through to the inner side of the thigh with two blunt steel pins, over these pins he runs a figure of eight with rubber tubing; including between one pin and the tubing the tissue which will form the anterior flap, and between the other pin and tube the posterior flap.

Senn makes a typical resection cut but does not remove the head and neck of the bone. Instead of the steel pins he draws a piece of rubber tubing through the thigh, tying it anteriorly and posteriorly as well as taking one turn of it around the entire circumference of the limb. The subsequent steps of Trendelenburg's and Senn's operations are alike.

There is certainly enough similarity between the old operations of Volkmann and Trendelenburg and the new ones of Wyeth and Senn to designate the latter as modifications of already known methods rather than as new operations.

Progress of Medical Science.

Vagino-fixation of the Uterus.—Dr. Mackenrodt refers to the fact that Winter recently reported fourteen cases of vagino fixation performed according to his (Mackenrodt's) method, all of which were unsuccessful, and attributes the bad result to wrong technique. The writer insists upon the importance of the following steps: A median incision is first made in the anterior vaginal wall, extending from the portio to the most prominent part of the urethro-vaginal septum, and the flaps are dissected off laterally. The cervix is then grasped with the bullet forceps and is drawn forcibly downward, while the urethral prominence is drawn upward. The bladder is dissected away from the uterus as high as the vesico uterine fold of peritoneum. The vaginal flaps are now held apart, and a curved transverse incision is made in the vesico-vaginal septum at the lower angle of the wound. A sound is passed into the uterus, and the organ is anteverted, the peritoneum being stripped from the fundus of the bladder sufficiently. The raw surface on the protruding portion of the bladder is now closed with a continuous suture, not only to check oozing and to prevent the formation of a pocket between the uterus, vagina, and bladder, but to approximate the point of fixation of the fundus uteri to the symphysis. If prolapsus exists, the vagina is narrowed by excising the flaps made, and suturing. The final step in the operation consists in fixing the fundus uteri by passing two silk sutures first through the outer edges of the vaginal wound just below the urethral prominence, then into the corpus uteri as high up as possible, and the vesico-uterine pouch, then downward across the vaginal wound so as to emerge at a point an inch lower on the opposite side. The sutures being tied form a cross. The remainder of the vaginal wound is then closed with catgut sutures, and is at the same time united to the cervix. The silk sutures are left *in situ* from six to eight weeks. The fixation of the uterus is obtained through union of the opposed folds of the vesico-uterine pouch. Slight flexion of the uterus is maintained by the crossing of the sutures. If the cervix is very long, it is amputated.

The writer has performed this operation thirty-one times; thirteen cases were entirely successful, three women subsequently becoming pregnant, one twice. Six women in all afterward became pregnant; three were delivered spontaneously and one with forceps, the uterus remaining in the former position after involution had taken place.

Dührssen, in a lengthy paper, discusses Mackenrodt's operation, which, he says, is essentially the same as the one previously described by himself, with the exception of the first step—splitting the anterior vaginal wall—which is superfluous, as well as suturing the lower portion of the bladder and attaching the vaginal flaps to the cervix. Moreover, there is the risk not only of wounding the bladder and causing a fistula, or of actually contracting the viscus, but of forming a dangerous pocket between the bladder and the vagina. In his own operation (which can be completed in from ten to fifteen minutes) the writer simply opens the anterior fornix, pushes the bladder toward the symphysis with catheter and forefinger, while the cervix uteri is drawn downward and backward, and by means of temporary sutures gradually draws down the uterus until permanent sutures can be passed through the vesico-uterine pouch and fundus. The patient need be kept in bed only a week. This operation he has performed forty times with perfect success.

Steinbüchel reports four cases of vagino fixation, performed according to Mackenrodt's method, the results of which were quite satisfactory. The operation was modified by prolonging the median vaginal incision downward, and making an oval denudation when the vagina was much relaxed. Moreover, the peritoneum was dissected away from the fundus as far as possible, so that the sutures could be passed into it higher up. When these were fastened to the lower edges of the vaginal wound, prolapse of the bladder was prevented, and the uterus was firmly fixed in the desired position. Additional sutures were then passed through the uterus, thus bringing the anterior raw surface of the organ more directly in contact with the vaginal wound than in the original operation.—*The American Journal of the Medical Sciences.*

Nervous Lesions in Diphtheria.—Dr. Stscherbak has published an account of some experimental researches which have been carried out in Professor Strauss's laboratory. A summary of this paper is given by Dr. Rosenbach. The animals experimented upon were rabbits and guinea-pigs, and they were inoculated with diphtheritic bouillon cultures or the filtrate of these. Many alterations were found in the nervous system of such animals after the inoculation, such as hemorrhages in the spinal meninges and in the gray matter of the cord, acute inflammation of the latter, degenerative changes in the spinal roots, neuritis of peripheral nerves, and changes in the muscles, both parenchymatous and interstitial. Similar changes have been described by various observers as occurring in patients who have died from diphtheria, and Dr. Stscherbak's researches would seem to indicate that they are a direct result of the disease. Besides showing the correspondence between the conditions observed in man and those produced by inoculation in animals, however, these experiments indicate also the cause of diphtheritic paralysis as essentially consisting in inflammation of the peripheral nerves, the other changes in the nervous system being of subordinate importance and significance. In all the cases in which paralysis followed the inoculation in these animals neuritic changes in the peripheral nerves were found. The intensity and extent of the neuritis corresponded generally with the degree and locality of the paralysis. The fibres of the peripheral nerves going to muscles were mostly affected. The neuritic processes were found to be independent of changes in the spinal cord and the latter were present in cases in which there was no paralysis.—*Neurologisches Centralblatt.*

DRUGS AND "HEART FAILURE."

By CHARLES E. PAGE, M.D.,
BOSTON, MASS.

An important editorial in the *Boston Globe* not long ago, in commenting on the action of the Philadelphia Board of Health in refusing longer to accept "heart failure" as the cause of any death, undertakes to expose the ignorance on the part of medical men which has brought this term into common use.

Whatever may have been the motive of this action on the part of the Board of Health, whether it were the belief that many of these fatalities result from drug poisoning, or simply to encourage greater care in describing the remote causes of death, it is the writer's belief, based on many years' observation in active practise, that fatalities are constantly occurring as the direct and natural effect of so-called medicinal doses of virulent poisons. To weak and exhausted patients the smallest dose may prove as inimical to life as the heaviest amounts administered for homicidal purposes.

Whether or no there be the slightest ground for this opinion, what must we think of preaching and practise like the following, in which, despite the confession that the patients "died cured," the impression is sought to be made that the treatment probably prolonged the lives that went out so suddenly shortly thereafter?

A physician prominent enough in the medical world to be imported from Philadelphia to give a course of lectures before the Harvard Medical School Association related the story of two brilliant cures of a certain form of heart disease under his treatment when he was a young man, by "enormous doses" of digitalis. Both patients had been taking ten-drop doses, and he increased the dose to forty drops.

"The triumph seemed complete," said the lecturer, "and so it was for weeks; but mark the ultimate result. Mary, one morning, as she trod the doorway of the market-house, fell dead upon the threshold. The banker, stretching his arm across the desk that had been to him the pathway to riches and power, fell hushed and powerless into the eternal silence."

Here was the point, as it seemed to me and, I trust, to others who listened to his address, for the speaker to warn in the most emphatic manner possible against such brutal treatment, or to make his bow and allow his hearers to draw their own moral. But, so far from doing this, the lecturer expressed the belief that it was the forty-drop doses in place of the ten-drop doses that eked out poor Mary's life a few weeks, and that the banker also would have died sooner but for the same enormous doses of one of our most deadly poisons!

The writer has had the after-management of quite a number of "digitalis hearts," but he has never sought to remedy the evil in any case by increasing the dose of digitalis. On the contrary, he has always stopped the use of the drug short off, and has never had occasion to regret such action. I can see no difference between increasing the dose of digitalis from ten drops to forty in treating a digitalis heart, and ordering a man with a "tobacco heart" to smoke twelve heavy cigars in place of the three he is already taking.

Personally, I have for the past thirty-five years been cultivating a tobacco heart, with occasional lapses from vice to virtue, during which I would always improve in various ways. After smoking several cigars a day for months my system gets pretty thoroughly saturated with the drug and I feel the necessity of complete abstinence, and, as I have remarked, I always find relief therefrom; but whenever I have at such times gone to the other extreme, smoking, say eight or ten cigars in an evening, as on a club night, I have observed most excellent effects for the time being from the increased dose, like unto those chronicled above from the lecture on digitalis. The next morning, however, always told a different story.

Doubtless every old smoker will be able to recall similar experiences, although he may have learned a false lesson therefrom, as did the professor from his observations with digitalis. Certainly no bed-rock student of the laws of life but must feel a cold chill along the spine at the thought of the effect of such teaching on the minds of the tyros who listened. Years of experience will teach the rare few among them better things, but these will have in after years many painful recollections; while the great proportion of pupils are likely to continue and end about as they began.

867 BOYLSTON STREET.

TREATMENT OF DIPHTHERIA BY EUCALYPTUS.

By LEONARD LANDES, M.D.,
NEW YORK.

In my investigations of the subject of diphtheria I extended my inquiries to various countries of the Old World, as well as this, and through the kindness of Mr. E. C. Little, General Consular Agent for the United States of America at Cairo, Egypt, I received a communication from Dr. A. Murison, a Scotch physician practising in Cairo and official physician to the American Consulate there; and, among other statements regarding diphtheria in that part of the world, Dr. Murison says that in the treatment of the disease bichloride of mercury is the general remedy, and the general result is death. Dr. Murison followed that treatment for some time, with the result stated, until he saw that a Russian doctor advocated the use of eucalyptus oil, and he used that remedy in the last ten or twelve cases that he treated, with the most happy results. He recommended it to his friends, who also used it successfully, not losing a single patient.

His method is to take one part of eucalyptus oil and three parts of almond oil, giving one teaspoonful of the mixture every hour. Before the mixture is given a gargle of pure oil is used if the child is old enough, and if not a spray instead, and both, if it can be managed; also saturating the shirt and pillow of the patient with pure oil. and placing plates filled with the oil about the room. The ordinary rules of attending to the bowels, giving as much food as possible, securing plenty of pure air by open doors and windows, and maintaining cheerful surroundings, are to be observed. If signs of intoxication appear, reduce the dose to one-fourth the quantity.

I have suggested the above treatment to a few of my friends, who promise to try it, as I shall myself when opportunity presents itself; and I would recommend the medical profession to give it a trial: and I would be obliged to those who do so if they will let me know the result, as I am preparing a paper on the subject.

I have also received a communication from Dr. George Helstron, chief physician of the Epidemic Hospital at Stockholm, Sweden, for the year 1893, in which he says: "Our treatment is founded on the supposition of diphtheria being a local disease, with the production and absorption of toxical substances from the infected quarter; therefore at the Epidemic Hospital of Stockholm the galvano-cautery has been used for destroying the membrane." The treatment brought good results, and Dr. Helstron recommends me to give it a trial when suitable occasion offers.

Stitching the Bladder in Supra-pubic Lithotomy.—Close the lower third of the wound with No. 1 catgut, the stitches not entering the mucous coat; then place two tubes in the bladder, and suture the upper part of the wound. Iodoform gauze is tucked in between the tubes and the pubis. By the fifth or sixth day the tubes are removed, and the urine drawn off by catheter for a few days; but even though it should flow through the wound, it does not delay healing.—GUYON.

THE DANGERS OF CHLORAL.

THE unfortunate death of Professor Tyndall through an overdose of chloral has excited wide interest and regret. Professor Tyndall was in rather poor health and suffered from insomnia. He was accustomed to take a dose of chloral at night, and a solution of sulphate of magnesia in the morning. By mistake his wife administered the chloral solution instead of that of the salts.

When chloral was first introduced it was by far the best hypnotic which we possessed. It was very extensively used in consequence, and very soon reports of its occasional dangerous character began to come in. The profession learned to look upon it with some suspicion, and of late years one rarely hears of fatal results from its use.

A few cases have been reported of death being caused by a dose of about thirty grains. A dose of three grains has been fatal to a child one year of age. In many instances doses of fifty-five, sixty, and eighty grains have produced alarming symptoms. Old people are said not to bear it so well as adults, while children bear it better; and Bouchut considers doses of fifteen to twenty-three grains safe for children of from one to three years of age. Death has occurred from a dose of forty-five grains given to a child of five years.

Chloral is very often prescribed in doses of thirty and forty grains, and the danger from such doses is practically very slight in adults not debilitated by some disease. Any dose below thirty grains may be considered absolutely safe to an adult.

The amount which may sometimes be taken with impunity is very large. A case is reported (Blyth) in which a patient recovered from a dose of one ounce. A medical man, Dr. Maujot, took three drachms without any serious result.

In chloral poisoning much can be done by prompt treatment. After evacuating the contents of the stomach, strong coffee and strychnia should be given, the patient should then be wrapped in blankets and hot bottles placed about him. The temperature of the room should be raised. Lauder Brunton found that by poisoning animals with chloral, then wrapping them up and keeping them in a warm chamber, they survived doses ordinarily lethal.

Lupus.—Continuous compresses of five per cent. iodoform in cod-liver oil.—CHOUT.

LONG-CONTINUED FEVERS IN THE SOUTH.

No clinical question is of greater interest to the profession in the Southern States than that of the etiology of some of the long-continued fevers with which they have to do. Heretofore many, if not most, of the latter have been classified under the term "malarial," but the progressive men of that section are beginning to trace more carefully the peculiarities of this class of maladies, and to untangle the web of typhoid and typho-malarial manifestations which has hitherto been so complex.

Many of the older practitioners of the Gulf States have been disinclined to admit the occurrence in those regions of plain, uncomplicated typhoid fever. That it does show itself there can be no longer doubted. Probably many of the so-called typho-malarias are really simple typhoid modified perhaps by climatic influences. In a recent discussion of this subject before the Orleans Parish Medical Society, Dr. Martin read a paper on this topic, in which he describes a fever which he considers to be quite different from either of these two forms. It is usually ushered in without any premonitory symptoms. The patient usually complains of feeling dull; the tongue may or may not be coated; the bowels costive; loss of appetite; sometimes nausea and slight elevation of temperature; seldom any functional disturbance. The temperature will vary from 99° to 103° F., and the fever will continue from three to nine weeks. Patients are not greatly exhausted by the fever, and are sometimes able to keep about their work. One case which he had under treatment, a robust person, was never compelled to lie down during the day, but spent the time in a large arm-chair. The fever lasted ten weeks. In this case, its long continuance was partly due to malnutrition. Nausea complicated the treatment, and the question of nutrition became a serious problem, until he had recourse to raw eggs and sherry; this constituted the nourishment during the day, the patient taking as many as half a dozen eggs in twelve hours. At night he gave mulled milk, which proved a soothing and nutritious beverage. Through the entire course of the illness he was at a loss to detect any one symptom sufficiently marked to point to a diagnosis. If malarial, it was not typical in appearance. A careful examination of all the organs revealed no focus for a possible sepsis. All medication proved useless. Quinine was inert, and antipyretics gave but temporary relief.

In the discussion which followed the reading of Dr. Martin's paper many interesting facts were brought out. The opinion was expressed that typhoid may be changing its type at the present time, for we know that the clinical picture of more than one disease may, and does, change from one decade to another, and even from year to year. Right here in New York typhoid fever varies much from autumn to autumn. Some years show diarrhœa as a prominent symptom, or hemorrhages, or high temperature. The next year may present altogether different features. Another speaker, who had seen much of the slow continued fever, remarked that it assumed a distinctly intermittent character, which was not, however, at all affected by quinine. Several thought it essentially malarial with an added septic element, as it flourished in unhygienic surroundings, seemed to be propagated by sewer-gas, and was more common among those who ate fruits purchased in the open market. The possibility of added sepsis seemed

borne out by the experience of one speaker, who had seen great good result from antiseptic intestinal irrigation. The absorption of gastro intestinal ptomaines was suggested as a point of departure for the origin of the symptom-complex.

Nearly all the gentlemen participating in the discussion had had fatal cases, but the autopsies had revealed no distinctive lesions. Some had the typical changes in the Peyer plaques, while others had not. Moreover, alterations in these plaques, indistinguishable, at least to the naked eye, from those of true typhoid fever, had been noted in measles and in other affections. So there was, from the standpoint of pathological anatomy, no criterion for diagnosis. No sufficiently careful examination had been made of the blood, either for the germ of Laveran or the bacillus of Eberth, to furnish any aid from the side of bacteriology.

We are sure that the careful attention which our Southern friends are giving to this subject will do much for medical knowledge, and it is an ungracious task for us, who live here in a region comparatively free from pure malaria, to make any criticism upon their efforts. At the same time the position which many Southern physicians take upon this question, particularly those who have always lived in the South, is largely one of reluctance to admit that typhoid fever, pure and simple, is an endemic disease in their respective localities. We, of the North, are surprised at nothing which may appear in the course of typhoid. It is a hydra-headed malady, so far at least as complications are concerned, and the groupings of symptoms which extend over the widest range. The disease is not predicated on mere severity, for many cases are mild; not upon mere duration, for we frequently have abortive forms which run their course in two weeks; not upon eruption or hemorrhages or diarrhœa, for these are frequently all absent. In fact, in many of the milder atypical cases the diagnosis must be made by exclusion. From all we can learn, we believe that true typhoid is more common in the Southern States than the local physicians seem willing to admit, and the seeming logic of their attitude is, to a certain extent, influenced by tradition.

It is to be hoped that the medical societies of that portion of our country will make careful studies of these slow continued fevers in the light of modern bacteriology. They have an ample supply of clinical material, and such studies, emanating from men of the professional standing of those from whom we have quoted, will be looked upon as of the highest scientific value.

THE DOCTOR'S PRESENTS.

Now is the time of year when grateful patients sometimes take the opportunity of showing to their physician their appreciation of the inadequacy of a check to compensate for the help they have received. It is a time, too, when poor patients, whom the doctor has attended gratuitously, sometimes proffer acknowledgment of their gratitude. There is no doubt that these evidences of thoughtfulness on the part of patients give great pleasure to the hard-working doctor who gets them. It is not the value or the crude utility of the gift that arouses the pleasantest feelings. It is much oftener the recognition, unexpected perhaps, that one's services were held at a higher than monetary value, and that they led to feelings of personal affection and esteem. The physician has this exceptional advantage over those of other callings, that in the course of his professional duties he has daily opportunities of doing work which is, in the truest sense of the word, benevolent. "Possibly," says a contemporary, "physicians form the most truly charitable section of the community, not on the strength of that rule of professional etiquette which requires any practitioner to treat a brother's family gratis, but because of the very great extension of this habit to persons of no professional connection, for no other reason than that of downright, straight-out kindness of heart. The medical profession is instinctively possessed of the sense that it holds to an unusual extent a trust for the benefit of humanity, and that scarcely any man can call on it in vain."

That physicians as a class do exercise this philanthropic sense cannot be denied, despite the occasional evidences of sordidness and extortion which are made public.

We are not writing this in praise of medical benevolence. Doctors are much like other people. But they have opportunities for charity which they do not slight, but use freely and generously. We may be permitted at this season to remind ourselves of this sunny side to professional morals. The world loves to show up the rifts and seams as often as it can.

A HOSPITAL CAR.

A NOVEL suggestion has been made in the city of St. Louis which, if it prove to be practicable, will revolutionize the transportation of the sick and injured in large cities. It is, in short, nothing less than the employment of cars running on the various street railway lines, for ambulances, the motive power being whatever the particular corporation whose lines are made use of employs. The car is to be fitted up as a first-class ambulance, and the equipment can, from the additional room gained over an ordinary vehicle, be made more complete than is possible in the latter. It is believed that transportation by this method will lessen the suffering of the patient, that time will be saved, and that the cost will, all things considered, be no greater than now obtains with the ordinary system.

The car is to be run on schedule time, according to the rules governing traffic on the various lines. The driver, motor-man, or grip-man, is to be employed by the company, who will furnish transportation on terms to be agreed upon, while the city or the institutions interested will supply the medical attendant.

In St. Louis the problem is somewhat simplified by the geographical features of the city, and the fact that, by the laying of a comparatively short length of new track all the institutions can be reached along one general route. The car is to start from a central point at fixed hours. This central point is to have a receiving station or dispensary. The police are to be acquainted with the time schedule, and could meet the car at convenient places. The car, as it follows its route, receives the patients and delivers them at the proper destination.

Of course, such a system cannot entirely do away with ambulances drawn by horses, which will be required for service in inaccessible localities at a distance from the car route.

Such in outline is the system proposed by our pro-

gressive Western friends. We are glad to have them make the trial, and will await its result with interest. If it prove successful it will mark a new epoch in the intramural transportation of the sick and injured.

Here in New York, with its multiplicity of surface lines and the various motive powers employed, such a plan would prove more difficult to follow: There is a generous rivalry among the ambulance hospitals to obtain as many "calls" as possible. This rivalry, quietly fostered by the managers, is exemplified by the conduct of the ambulance surgeons and drivers, who relish nothing better than a race to a point just on the border line of their own territory, where the ambulance from another institution has a common right. To get there first and secure the case is a glory approximating to that of making a "touch-down" on Manhattan field. To bowl along in a car, on a track behind the Fabian steps of an ordinary New York horse, would rob life of all its Alexandrian dreams.

Geographically, the problem is not so difficult in New York as might at first appear, for all our ambulance institutions are situated along east and west lines. On the East side are Gouverneur, St. Francis, Bellevue, Presbyterian, German, and Harlem Hospitals; while on the West we have Chambers Street, St. Vincent's, New York, Roosevelt, and Manhattan. It would not be possible to run a car on the lines of a single company on either side of the city, but we presume that the various routes to be utilized could be connected, so that the car could traverse them all.

In spite of occasional newspaper criticism, the ambulance system of New York is superb, and very well fulfils all requirements; yet, if the St. Louis plan demonstrates its own feasibility, we may be able to follow it with advantage both to the institutions and the public.

SHIP-OWNERS AND SHIPS' SURGEONS.

We have frequently commented upon the inadequacy of the medical service on many of the trans-Atlantic steamships, and the matter is again brought to our attention by the receipt of a small pamphlet by Charles Henry Leet, F.R.C.S., who exposes some of the glaring iniquities of a bad system. Mr. Leet is now engaged in a crusade to bring about the enactment by the English Parliament of certain measures which shall remedy existing abuses. He suggests the formation of an association of all medical officers of the merchant navy. Medical schools are to urge their alumni to petition for the passage of the new Shipping Bills, and particularly for the insertion of a clause which shall confer upon the ship's surgeon, powers analogous to those of a health officer on land, and further special powers for the protection of seamen. Ship owners are to be induced to support the clause in order that competent and seasoned ships' surgeons may be attracted. Seamen are to be encouraged to report insanitary conditions, etc., on shipboard.

All of these requests seem reasonable enough, but the present condition of the English merchant marine is, from a sanitary point of view, sadly in need of reform. Mr. Leet speaks keenly, for he has had experience with the White Star, Cunard, and other prominent lines to which he rendered able service, but from which he was discharged because he dared to speak the truth and would not submit to abuses. As he well points out, a doctor who protests against sanitary evils of any kind, to either owner or captain, is simply remonstrating with an evildoer on the error of his ways. He is their subordinate, and when he makes a complaint he casts an imputation on his own superior officer.

Under the proposed Shipping Bills it is hoped to make the surgeon a representative of the Maritime Board of Trade, to which he is directly responsible. He can then compel owners and captains to comply with all needful sanitary requirements, or else arraign them before the body mentioned.

It is a pleasure to learn that the recently established American line of steamers confers upon its surgeons full sanitary powers, and that its medical officers are men of recognized standing. On some of the English lines, notably the Cunard, it is expressly declared, in a recent order. by the company, that "the hospitals are to be under the surgeon's charge only when occupied by patients, at which time he will be responsible for their cleanliness and proper ventilation. When unoccupied, they are to be at the captain's disposal." In other words, the surgeon's duty is to care for sickness after it has actually occurred, and not to prevent it.

Not alone for the passengers, but also for the crew, is more and better protection needed. Poor Jack often suffers from the brutality of mates who would stand in wholesome awe of a properly commissioned sanitary officer.

The growth of abuses in this line has been a long one. A charge can come about only by slow degrees. We hope Mr. Leet will continue his propaganda, to which we give a most cordial support. Public sentiment ought to be aroused in every possible way to demand efficient medical service on all the lines so extensively patronized by Americans. If John Bull's pockets can be touched, he will perhaps become more considerate of his patrons.

Letting His Light Shine.—The following is a clipping from *The Cherokee Scout*, of Murphy, N. C., a country village weekly paper which thus allows one of its local medical celebrities to speak for himself. It is not necessary to mention the name of the man, as unfortunately it would not be recognized as famous by anyone outside of his particular preserve:

"I take this method of informing the public generally that I am now thoroughly equipped and prepared to, and hereby, tender my professional services in the practice of medicine, surgery, and obstetrics, being prepared to perform the most intricate operations in surgery and to treat the most stubborn chronic diseases. And in obstetrics I have my first case to lose in an active practice of twenty-five years, have attended hundreds without the slightest accident, never had even a slow recovery; and now, with a thorough medical training, coupled with an experience of twenty-five years' practice, I unhesitatingly announce that if you wish to be cured, call on or consult me, otherwise follow the advice of the prejudiced and the foolish and die. Hemorrhoids cured without the use of a knife."

Malignant Tumor of the testicle in children is rare. The prognosis is so grave that patients seem condemned to certain death within six months to a year.—Monod.

News of the Week.

Twelfth International Medical Congress.—The Russian Government has shown much interest in the meeting place for the Twelfth International Medical Congress, in 1896. It desires that Moscow be selected as the city, and promises to donate 50,000 roubles toward the expenses of the Congress.

Dr. Trudeau's House Burned.—The house and splendidly equipped laboratory of Dr. E. L. Trudeau, at his sanitarium at Saranac Lake, N. Y., were destroyed by fire December 4th, during Dr. Trudeau's absence in New York, where he is seriously ill.

The Peruvian Army Surgeon-General, Dr. Manuel Antonio Muniz, has presented to the Smithsonian Institution nineteen crania giving evidences of prehistoric trephining for surgical purposes. In some instances the patients died under the knife. In one instance, the patient survived the removal of a fragment four inches long and one and one-quarter inch wide. The resultant cavity was covered with silver. In one instance the patient survived two trephinings, but died after the third. The instruments used were flint, like those of the stone age (*Medical Standard,* Vol. XIV., p. 83). These skulls all have a persistent frontal suture.

Tribute to Dr. Abraham Jacobi.—American scholarship has received a flattering recognition from the savants of the Old World, in the invitation recently extended Dr. Abraham Jacobi, of New York, to take the Chair of Pedology in the University of Berlin. This professorship has been ably filled for a period of twelve years by Dr. Henoch. The offer was received by Dr. Jacobi in the latter part of October, and his answer declining to accept the place was sent the same day by telegraph.

The Demilt Dispensary, New York.—Dr. W. L. Stowell writes: "In your issue of November 25th is an editorial relative to 'Doctors and Dispensaries,' in which you say of Demilt, 'its patronage remains practically the same as twenty years ago.' In 1872 the new patients numbered 23,692. In 1892, 30,111 new cases. An increase of twenty-seven per cent. is not 'practically the same.' This increase has occurred while five or more dispensaries have been located and grown on the same territory. It was recently regretted, in a public meeting at the Academy of Medicine, that laboratories did not exist at dispensaries. At Demilt we have a complete Zeiss microscope, than which no better exists in this city. The managers have never failed to aid in providing any requisite wanted in the pathological department. I write this, not that I am in accord with all views of the management, but because facts are better than generalization in discussion."

Conservative Cæsarean Section for Placenta Prævia.—On Sunday, November 19, 1893, Dr. A. C. Bernays, of St. Louis, performed the conservative Cæsarean section for placenta prævia centralis, saving both mother and child by the operation. Age of woman, forty-two years; German; fifth pregnancy; no attempts at delivery; eight months gestation; woman in good condition; had been in labor twelve hours. The operation was completed in twenty-four minutes and forty-five seconds. Woman was able to sit up on the fourteenth day after the operation. This is the first successful case of Cæsarean section for placenta prævia in the United States.

Pre-natal Determination of Sex.—Dr. George Abbott, of Hamburg, N. Y., writes: "Last summer I met with two cases near each other very confirmatory of my old-time observations and theory relative to the 'Determination of Sex,' and seeing a report from Dr. McAllister, of Driftwood, Pa., in point in your number of December 2, 1893, I will at once send them to you. About the middle of May last, Mr. L—— called to engage me to attend his wife in confinement, which was expected about the 26th or 28th inst., reckoning two hundred and eighty days from her last menstrual period. In the conversation I learned that their only intercourse had occurred some ten days later, and that no intercourse nowhere near that time, previously nor for weeks afterward, had occurred. On the strength of that assurance I told him his wife would not be likely to be confined until near two weeks later, and that he then would have a daughter, a prospect that pleased him much, as he then had several sons. I set two hundred and eighty days, from the date he gave me as the time of conception, as her time for confinement, and on that date I delivered her of a daughter. Shortly after I was called to attend a primapara, who gave me the following history: She was taken unwell October 16, 1892, was married the 17th, and believed herself to have conceived the 23d, being about the fourth day following the cessation of menstruation. I diagnosed a case of false alarm, and assured her that her full time would not be up until a week from the following Friday, when she should be confined and delivered of a daughter. On the day predicted I was again called, and delivered her of a daughter. I noticed a report from a doctor, in Ohio, whose name and address I have lost, in your journal some months since, also confirmatory of the same theory, viz., that conceptions just previous to the menstrual period result in boys; and if just after, in girls. I wish more doctors would note and publish their observations when the facts are reliable."

A New Work by Professor Koch.—The *National Zeitung* says that Professor Koch, the bacteriologist, will shortly publish an exhaustive work on an improved method of using tuberculine, and the diagnostic properties thereof. The work will also treat of the recognition of the first stages of consumption.

Dr. R. G. Bogue, an old and well-known physician of Chicago, died at his home there on December 7th. Dr. Bogue was born in New York in 1832, and in 1857 went to Chicago. He was one of the founders of the County Hospital. He was president of the Chicago Medical Society, and prominent in many other societies of physicians. He had been sick nearly ten years, and death was not unexpected.

A Hospital Staff Crippled.—It is stated that the surgical staff of Roosevelt Hospital is at present crippled by the illness of Drs. Douglas Ewell, Edwin M. Cox, and Clarence Collins. Dr. Ewell, who was formerly house physician, contracted blood-poisoning about two weeks ago, while dressing a scalp wound. It was found necessary to amputate a finger of his left hand. He was confined to his house at 75 East Fifty-sixth Street. Dr. Cox, the house surgeon, was attacked with typhoid fever on

Sunday, and has been dangerously ill. It was reported last night that he was out of danger. The third victim, Dr. Collins, an ambulance surgeon, has been suffering from hospital fever for several days. It is thought that he will be able to report for duty within a few days.

Army Medical Examining Board.—The Army Medical Examining Board, which has just concluded its meeting in Washington, had thirty-four applicants registered for examination. Some of these failed to appear, and some did not reach the requisite physical standard, leaving twenty-four who were more or less fully examined. Of this number five were successful. The colleges represented by these successful candidates were the College of Physicians and Surgeons of New York City, South Carolina Medical College, Columbian University of Washington, University of Maryland, and the University of Pennsylvania.

Dr. J. B. Murphy, of Chicago, while on a brief visit to New York, was the recipient of many professional courtesies from the surgeons of the different hospitals, and had opportunities offered him of demonstrating the uses of his intestinal button.

A Census of the Physicians in New York.—Information has been received by the State Medical Society that many doctors who have no diplomas are practising medicine, and to get a full list of all the doctors who practise in this city the assistance of the police was requested. The captains detailed the men in districts so that they covered the entire precinct. They were instructed to copy the names and addresses from all the doctors' signs they came across. The work was completed in about two hours. The list will be submitted to the society, which will take measures to prosecute those who are practising illegally. There are between 3,500 and 4,000 physicians in the city.

The Harvard Medical School.—The position of dean of this school having been resigned by Dr. H. P. Bowditch, it is said to have been offered to Dr. William M. Richardson, professor of obstetrics. Among the subjects for the evening lectures is the anatomy and surgery of the gall-bladder, by Professor Maurice H. Richardson.

A Few Little Incidents of Foot-ball.—The *Lancet* has long made it a custom to chronicle the not inconsiderable mishaps that occur from time to time on the foot-ball field, and Dr. Amidon, of New York, has taken the pains to make a list from the *Lancet's* reports of those that came to the notice of the editor in the year 1892. How many casualties escaped notice cannot be told. In this year twenty-three deaths occurred in England that were directly traceable to foot-ball. Those indirect ones that occurred subsequently, or that will occur, are left for future historians. Here is Dr. Amidon's little list of the English accidents requiring hospital treatment: Concussion of brain, 3; injury to the head, 1; injury to the nose, 1; fracture of the nose, 1; fracture of the jaw, 1; fracture of the collar-bone, 20; dislocation of arm, 1; compound fracture of arm, 3; fracture of arm, 5; bad fracture of left arm, 2; serious injury to arm, 1; compound fracture of the elbow, 1; fracture of left wrist, 1; fracture of ribs, 3; severe sprain of thigh muscles, 1; fracture of thigh, 3; injury to leg, 1; fracture of leg, 29; bad fracture of leg, 1; compound fracture of leg, 5; fracture of knee-cap, 1; severe injury to knee-cap, 2; fracture of ankle, 3; dislocation of ankle, 1; sprained ankle, muscles, and tendons severely wrenched, 1; severe injury to foot, 1; fracture of spine, 1; serious injury to spine, 1; serious injury in groin, 1; severe internal injuries, 2; severe internal injuries, fatal in two days, 1; fatal abdominal injuries, 6; undescribed accidents followed by death, 3; undescribed accident followed by lock-jaw and death, 1. Total number of grave injuries, 109. For the year 1893 the returns are not yet in. In the *Lancet* of November 18th, there are recorded, as occurring during the preceding week, three cases of fractured leg; one of kick in abdomen, with death; one of concussion of spine; one of fractured clavicle; one of injury and death. This year, therefore, there have been at least twenty-eight deaths in England.

City Boards of Health Have no Inherent Power over City Government.—That boards of health created by city governments or auxiliary thereto have no power over same other than is relinquished to them, is brought out by the decision of the Supreme Court of Georgia in the case of Mayor, etc., of the City of Brunswick *vs.* King (17, *S. E. Rep.*, 949). Here the court said that the function of the above board was that of an advisory body, and of an agency to carry out such regulations in the matter of the public health, not inconsistent with the laws of the land, as the mayor and council, by their ordinances, might see fit to direct. The streets of the city being by its charter vested in fee simple in the mayor and council, with power to widen, extend, and straighten the same, and with power to open, lay out, and establish new streets, the necessary incidental power of grading and otherwise improving the streets and keeping them in repair was also in the mayor and council. None of these powers were withdrawn, abridged, or limited by the amended charter of the city, providing for the creation of a board of health and the election of a health officer. Therefore, ordinances passed under the authority of the amended charter, which did not expressly name the mayor and council as subject thereto, were not operative upon them when acting as a municipal body in the exercise of their corporate functions in improving or repairing the streets.—*Cincinnati Lancet and Clinic.*

Myopia among College Students.—The senior class at Yale numbers 185 students; of these 54 wear glasses, the necessity for such aids to vision having, in 25 of the cases, arisen since the students entered the College. The average age of the members of the class is twenty-two.

Diner des Infécondes.—A small company of select demi-mondaines has just instituted a *diner des infécondes*, under the honorary presidency of a surgeon noted for the readiness with which he performs ovariotomy. This charming company of patients who have been operated upon meets for dinner each month, the surgeon presiding at the table. The novelty of this form of vicarious menstruation is truly Parisian.—*Boston Medical and Surgical Journal.*

Hernia after Operations for Appendicitis.—A contemporary states that one instrument maker in New York has sold within the past year no fewer than six dozen special trusses for ventral hernia following operations for appendicitis.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 7, 1893.

D. B. St. John Roosa, M.D., President, in the Chair.

Nominations for Office.—Nominations were made as follows, one candidate to be elected for each office: Vice-President, Robert W. Taylor, Joseph D. Bryant, W. P. Northrup; Trustee, A. Jacobi, Edward S. Peck, W. H. Katzenbach; Committee on Admission, John S. Warren, Andrew F. Currier; Committee on Library, William Gilman Thomson, John W. Brannan, S. T. Armstrong.

Amendments to the By-laws.—The following amendments to the by laws were adopted: 1. No section is authorized to institute any procedure that is of a public character without first submitting the project to the consideration and approval of the Academy. 2. Special meetings may be called at any time by the chairman of a section upon the requisition in writing of ten fellows assigned to that section. The announcements of such special meetings are to be printed and mailed to each fellow of the Academy, at the expense of the Academy. 3. An amendment essentially as follows: A resolution involving new business, or pertaining to a subject that is not germane to the matter announced for consideration at an Academy meeting, must be mailed separately to each member at least one week in advance of the meeting.

Bureau of Trained Nurses.—At the recommendation of the Council resolutions were adopted providing for the establishment of a bureau of trained nurses in the Academy building, the President being empowered to appoint a committee of five to carry out the purport of the resolutions.

Intestinal Anastomosis.—The discussion for the evening was in charge of the Surgical Section, the Chairman of which, Dr. Joseph D. Bryant, occupied a seat by the President on the platform. Dr. J. B. Murphy, of Chicago, read the paper, in which special attention was given to the following points: 1, The means of producing union of divided intestinal tissues; 2, the comparative value of end to end and lateral intestinal approximation; 3, cholecystenterostomy; 4, post-operative narrowing of the interintestinal communications; 5, the influence of time employed in operation, as bearing on consequent shock and peritonitis.

The discussion which followed was participated in by Drs. W. W. Keen, R. F. Weir, Robert Abbe, and B. F. Curtis.

Danger of Obstruction by the Button and of Cicatricial Constriction.—Dr. W. W. Keen, of Philadelphia, said he had performed an anastomosis on the digestive tract in but a limited number of cases, eight all told; four cases of gastro-enterostomy, four of intestinal anastomosis proper. Of the cases of gastro-enterostomy one died after twenty months; one of exhaustion after the eleventh week; the third was living at the end of eighteen months; the fourth at the end of a year. Of the four cases of intestinal anastomosis one died at the end of forty-seven days, of a lesion independent of the operation. That was the only case in which he had used Murphy's button. The second case died the eleventh day after the operation, of exhaustion. The third was believed to be still living at the end of a year. The fourth died within twenty-four hours after the operation for resection of the colon and lateral anastomosis. With his present experience, he thought that in a similar case he would prefer to leave the carcinoma intact and do lateral anastomosis alone. The means which he had used had been, in one, Murphy's button; in one, the segmented ring of Ashton and Baldy; and in the others, Abbe's catgut rings.

In intestinal anastomosis there were four requisites, whatever the method used: 1, Simplicity of execution; 2, speed; 3, security: 4, that the opening shall be of sufficient calibre to obviate subsequent obstruction by cicatricial contraction. The methods had been named by the author as follows: 1, Suture alone; 2, suture and mechanical means; 3, mechanical means alone.

The first requirement named he was sure had been fully met by the button, which he regarded as one of the most ingenious mechanical appliances in the whole domain of surgery. With reference to speed, the button was again far in advance of any other means yet devised. He also thought it offered as secure, probably a more secure, method than any other. In the case in which he had used the button he had depended on it alone, using no sutures, and it had secured perfect anastomosis. But what seemed to him would be likely to prove a fatal objection to it, was failure to establish an opening of sufficient size to be a guarantee against subsequent obstruction to the passage of the intestinal contents. In his own case, of which he exhibited the specimen, the subsequent narrowing had been considerable, and the explanation therefor in the disappearance of œdema, which he had understood the author to accept, could not have been the correct one, for the reason that the œdematous or diseased structure had been excised and union had been made between healthy portions of the gut.

While the tendency in New York had been to discourage the use of mechanical means in intestinal anastomosis, Dr. Keen personally confessed to preference for such means over suturing alone, and especially for the mechanical means known as Abbe's rings. He felt, however, that that very large opening proposed by Abbe of late, say four inches in length, was needlessly large. Some of the objections which had been made to the button did not seem to him to be valid ones. For example, he did not think pressure necrosis would extend beyond the compressed tissue between the two halves of the button. As already stated, the most serious objection was danger of subsequent contraction to such an extent that the intestinal contents could no longer pass. A lesser danger, one which he felt was real in spite of the fact that it had not yet occurred, was that of intestinal obstruction from failure of the button to pass through the intestine, especially at the ileo-cæcal valve.

One of the conditions in which the button would prove superior to all other means yet at our disposal, was in the operation of cholecystenterostomy, one of the most difficult operations in abdominal surgery. Inasmuch as nothing but fluids had to pass through the artificial opening, this was less likely to contract to the extent of producing subsequent occlusion, and a button of moderate size being used, it probably would pass successfully through the ileo cæcal valve.

Dr. R. F. Weir believed, as Dr. Keen had expressed himself, that the condition in which the button would prove to be especially useful was in making communication between the gall-bladder and intestine after failure to do away with the obstruction in the gall-passages. Like him, too, he had had some fear that the button might not get out of the intestine, notwithstanding the fact that this accident had not yet happened, according to the cases reported by Dr. Murphy. In gastro-intestinal union he thought mechanical means should be discarded. Experience in New York went to show that they had not afforded sufficient opening between the intestine and stomach. He had performed this operation, using Abbe's rings in one case, in one case sutures alone, taking not more than forty minutes from the time of opening the abdomen to closing it. As to the plugs or buttons shown for lateral anastomosis, he did not feel that one would be warranted in using them of so great size, lest they should fail subsequently to pass the ileo cæcal valve. Yet it was necessary, in his opinion, to make the opening three and a half to four inches long, in order to obviate occlusion by cicatricial contraction.

Dr. Weir showed a man who had been operated upon by a surgeon for hernia, who afterward developed an abdominal tumor supposed to be malignant, who was then subjected by a colleague to exploratory incision and union

of the cæcum with the abdominal walls preparatory to further operation, should this prove necessary. His symptoms becoming more severe, he passed into the hands of Dr. Weir, who explained to him the advantages of intestinal anastomosis over a temporary opening into the gut at the place where it had been attached to the abdominal walls, but told him also that anastomosis would be attended by greater danger. He chose anastomosis. Lateral union was made with an opening two inches and a half long, yet, in spite of the fact that only half a year had elapsed, there were now symptoms of recurring obstruction, although it was impossible to say whether the obstruction was due to contraction of this large opening or to omental adhesions. The diagnosis of malignant growth had been made and abandoned, the tumor having diminished in size, pointing to subsidence of a simple inflammatory and œdematous condition of the omentum at the site of the previous hernia.

He also presented a specimen in a case of anastomosis between the stomach and intestine, illustrating the possibility of accident from use of mechanical means, catgut rings having been employed which twisted and led to fatal hemorrhage. He further showed Murphy's button on a specimen illustrating cholecystenterostomy. The application of the button to cases of rectal stricture, as described in the paper, he felt was a very valuable suggestion.

A Needle and Thread Sufficient, and to be Had Everywhere.—Dr. Robert Abbe felt the untrustworthiness of statistics. They furnished but an imperfect basis on which to found impressions and guides. The paper contained statistics which he had not heard of, and left out others which were familiar in the East, especially with regard to the rings. Various devices had been brought forward for making ready anastomosis, but even the bone-plates, which at first promised so much, had been discarded because of serious objections. Any surgeon who was dexterous with the needle and thread, had a method always at hand which would serve him well in making intestinal anastomosis. The statistics of end to end anastomosis of the intestine had been based upon past imperfect methods, and therefore required revision. The reason why he had proposed so long an incision in lateral anastomosis was the fact that in four striking cases the necessity for this was demonstrated. In two he made the opening an inch and a half long, they died at the end of six months, of malignant disease, and in one the autopsy showed that the opening had contracted down to a quarter of an inch, and in the other to a small aperture which the tip of the little finger would hardly enter. The other cases were operated upon two years and a half ago, longer openings being made, and they were well to-day. The law of contraction in cicatricial tissue should always be borne in mind when making anastomosis.

When it came to the question of time, Murphy's button was brilliant. It was apparently the climax of surgical ingenuity. If it should prove that there was less danger of cicatricial contraction from the circular scar of end to end anastomosis, and this could be obtained with the button without danger of subsequent blocking of the gut, its use would prove a decided advance. It was, however, in cholecystenterostomy that the button had so far won laurels, and he thought deservedly so. It was known, however, that quite large gall-stones ulcerated through into the intestine and the opening afterward closed, as shown post mortem, and it might be that the opening made by the button would also close; but unless it should become completely occluded it would permit the passage of the bile. When gall-stone was the cause of the obstruction it should, if possible, be removed from the duct. The cases especially adapted to the use of the button were those of malignant obstruction of the duct, since the disease would probably run its course before there was time for cicatricial occlusion. He attributed the improved statistics of to-day to the surgeon's ability to do clean peritoneal work.

Dr. B. F. Curtis thought that all must admire the ingenuity of the Murphy button, but, as it had already been stated, there were objections to it. There was hope that in the future the ingenious contrivance would triumph over the danger of stenosis and intestinal obstruction. The principal argument which had been advanced in favor of mechanical aids was a saving of time. There was no doubt that the length of the operation in certain cases had a very important influence on the result. Operations were for two classes of cases, namely, the chronic, where the question of time was of little importance, and the acute, where the question of time was of very great importance. In the former, of course, the chief indication for the button, as for other mechanical aids, was absent. In the latter, the necessity for a quick operation could be met by making the preliminary artificial anus. Another advantage in taking this course was in the fact that the obstruction calling for interference sometimes disappeared after the indication for immediate relief had been met. There was no danger of the temporary opening into the gut remaining permanent.

Dr. Murphy closed the discussion. The speakers had expressed the same doubts as regards the dangers attending the use of the button which he had felt in some degree himself, until experience had shown them to be apparently without foundation. At least the danger of cicatricial contraction after end to end anastomosis was less than that attending union by the Czerny-Lembert suture. It secured the largest possible opening by end to end union, with the least possible amount of cicatricial tissue. Cicatricial contraction had been shown to be due to fibrous deposit, and this was less in approximation by the button than by any other method.

What surgeon would feel the least worry if a mother brought to him a child who had swallowed a penny or even a twenty-five cent piece? He would tell her to go home and give no more thought to the matter. Dr. Murphy did not believe that there was any danger of the button failing to pass through the intestine, except there were some pathological condition.

Regarding Dr. Abbe's criticisms as to the statistics which he had presented, he could only say they had been compiled by one who had collected statistics for Senn, which showed his entire reliability; moreover he had been unaware of what use they were to be put to.

The explanation of the contraction following the use of the button in Dr. Keen's case, as suggested by Dr. Mayo, had not been subsidence of œdema, but return from a state of distention by gases, etc., during existence of obstruction, to the normal size after operation.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, November 23, 1893.

H. J. Boldt, M.D., Chairman.

Case of Rudimentary Vagina, Uterus, and Ovaries.—The chairman, Dr. Boldt, presented a young woman, twenty years of age, in whom examination revealed a very small vagina ending in a blind pouch, also only the rudiment of a uterus, and so far as could be determined by touch alone, entire absence of ovaries. It was probable however, that the ovaries also existed in a rudimentary state since there was slight menstrual molimina.

The chairman had recently read the report of a case of rudimentary vagina in which the physician had tried to cut down to the uterus and found absence of this organ. He thought that there should be no excuse for failure to make diagnosis of absence of the uterus before undertaking any operative procedure. He also said that doubtless many cases of rudimentary development of the sexual organs were reported by more than one observer because the name of the patient had not been given. He therefore wished to append the name of the patient in this case, which was A. Goodman. Inasmuch as the molimina was only slight he had advised against an operation.

Dr. A. F. Currier referred to a case seen by him, in which a young woman, fifteen years old, had absence of vagina while all the other sexual organs were well formed. In her case the menstrual molimina caused the formation of a tumor which finally opened into the rectum. A drainage-tube was then inserted through this opening into the uterus, but it was afterward for some reason removed, and the opening closed and led to the reformation of a tumor. He saw her again last May, when she was going through the same experience a second time. He advised the removal of the ovaries and performed the operation. He was asked what would be the result if the girl should marry, and replied that it would probably be serious, for the reason that the husband would have legal ground for divorce. He was therefore requested, if possible, to form a vagina, which he undertook by the use of graduated dilating glass bougies, and finally succeeded in getting a passage which was two inches long by two and one half inches in circumference. During the process of dilatation he unfortunately opened the bladder, but the wound healed promptly, so that no trouble ensued.

Dr. Stanard said he had once seen a similar case to Dr. Currier's in the practice of Dr. W. H. Baker, of Boston. The uterus was rudimentary, the vagina was extremely short, not reaching up to the uterus. As the patient wished to marry, Dr. Baker undertook to make dissection up to the uterus, but met with an unexpected difficulty, namely, extreme thinness of tissue between the vagina and the rectum, which led to the formation of a recto-vaginal fistula. Therefore he did not succeed in carrying the dissection up as far as the rudimentary uterus.

Submucous Fibro-myoma together with Tubo-Ovarian Diseases Mistaken for Multiple Fibroids of the Uterus; Hysterectomy; Recovery.—Dr. Stanard presented specimens of a case whose chief interest centred in a mistake in diagnosis. The specimen, consisted of a uterus about five by four by three inches, its interior occupied by a tumor in the shape of an inverted cone, attached to its fundus. He had been unable with the finger, which had been introduced with difficulty through the small hymen, to make out the demarcation between the cervix and the tumor projecting from it. He felt less hesitation in stating this fact since two eminent specialists had made the same error in diagnosis. At the operation the uterus was found very symmetrical in form, the tubes and ovaries the seat of disease; and after extirpation by Goffe's method, leaving the dilated and thin cervix as a stump, the true nature of the uterine tumor was found to be submucous and not interstitial.

Probable Abdomino-Peritoneal Gestation Sac.—Dr. Stanard presented a second specimen consisting of the ovary, tube, and a fibrous sac independent of the tube and the ovary, which he believed to have been the seat of abdominal gestation. He was unable to account for the tumor under the circumstances related except on the basis that it had been the seat of extra-uterine pregnancy, although no embryonic growth was found to make this diagnosis a positive one. It was evident, however, from the appearance of the tubes, that if the sac were a gestation sac the ectopic pregnancy could not have been in the first place tubal.

In the discussion which followed Dr. Grandin referred to a case of pregnancy in which there was only a pin-hole opening in the hymen. Dr. Currier expressed preference for the complete removal of the uterus to any form of partial amputation. Dr. Boldt expressed doubt as to the sac in Dr. Stanard's case being the sac of ectopic gestation.

Diseased Tubes and Ovaries.—Dr. Currier presented the tubes and ovaries removed from a woman, twenty-one years of age, who had married at the age of sixteen and during one year past had followed the life of a prostitute. She had suffered eight or ten days every month from abdominal pains, cramps in the right leg, etc. He also presented the tubes and ovaries in a second case where there was a history of syphilis, sterility, disordered and painful menstruation, etc. In this case he found on one side a dermoid cyst, and on the other a certain amount of disease in the tubes and ovaries which led him to remove them, in spite of the fact that the patient had requested him to spare the organs on one side, if possible, as she objected to complete mutilation. This remark pertained also to the first case, and he was therefore led to raise the question whether one would be justified in complying with the request of the patient and leave organs on one side which he had reason to believe would be very liable to cause trouble in the future, although the extent of the disease was not striking to the unaided eye.

Dr. Ralph Waldo did not think we should leave the tubes on the other side when they were diseased beyond repair.

Dr. Porter thought the difficulty lay in determining what constituted beyond repair. All the facts in the case, including the patient's age, social relations, etc., should be taken into consideration. If she were anxious to bear children and was opposed to the sacrifice of both organs, he thought the surgeon might better take the chance of doing two operations than remove the appendages from both sides and thereby make subsequent pregnancy impossible.

A New Method of Controlling Uterine Hemorrhage by Means of Electrolysis.—Dr. A. H. Goelet exhibited a portable galvanic battery and a number of electrodes, in illustration of the method of checking uterine hemorrhage by use of the positive pole composed of copper, or by wrapping the ordinary positive electrode with cotton dipped in some metallic solution. The method was that which had been popularized by Dr. Gautier, of Paris, who first wrote upon it in 1891, and designated it interstitial electrolysis. By this means the salt at the positive pole was decomposed, so that its power upon the bleeding part was much greater and extended more deeply than where the ordinary electrode was employed. A piece of steak in which he plunged the positive copper electrode and passed a current of over a hundred milliampères a short time, showed an electrolytic process some distance around it, as indicated by the greenish tinge. The same thing took place when the electrode was introduced into the cavity of the uterus and brought into contact with the bleeding surface. It was of value in all cases where it was desired to apply an astringent to the mucous surface, as in endometritis, granular degeneration of the cervix, etc. Dr. Goelet related a case of hemorrhage in which the copper electrode with one hundred milliampères had controlled hemorrhage after failure with curettement. Frequently, however, twenty-five or thirty milliampères was sufficient. If necessary the treatment could be repeated when hemorrhage was not entirely controlled at the first sitting. He said that where physicians had met with failure in control of hemorrhage by the galvanic current it had often been due to the fact that the electrode had not been brought into contact with the entire hemorrhagic surface. This was especially liable to take place where the uterine canal was rendered tortuous by the presence of a tumor.

Dr. Currier said he had used copper electrodes similar to those presented by Dr. Goelet as long ago as four or five years, and had found that they did act admirably in controlling hemorrhage for the time being, but it had always seemed to him that it was due to the corrosive effect rather than to any particular hæmostatic effect of the copper. Then one difficulty with such large electrodes was that the operator could not confine the current to the exact point of hemorrhage, even if it were possible to determine where this was.

Dr. Goelet said it should be understood that the pole did not act as a cautery in controlling hemorrhage. He was somewhat surprised to hear that Dr. Currier had used copper electrodes within the uterus four or five years ago, for in that event he antedated European operators and should have credit for it. For his own part he had found

the result in controlling hemorrhage decidedly permanent. A greater or less amount of the electrode could be exposed according to the necessity of the case.

SECTION ON GENERAL MEDICINE.

Stated Meeting, November 21, 1893.

CHARLES E. QUIMBY, M.D., CHAIRMAN.

Changes in Therapeutics.—THE CHAIRMAN said that in arranging a discussion upon this general subject the desire was to sift the best methods of treatment from among the many which had prevailed from time to time, and not to criticise the disposition to change methods, since without some change no advance could be made

Variations of Therapeutics as Taught Within the Last Few Years.—DR. WILLIAM L. STOWELL, who had been requested to present a brief paper upon this subject, said he had not found the task an easy one, but he had tried to consult the leading authors of England, Germany, and America, chiefly on practice, to some extent on therapeutics, and in chronological order. Empirical treatment had seemed general during the first two-thirds of our century. Then Chambers gave new stimulus to thought by his views. These were given by Dr. Stowell, in condensed form, as were also in turn those of Watson, Hughes Bennett, Gairdner, Stillé and Maisch, Neimeyer, Wünderlich, Pfeuffer, Liebermeister and Willibrand, Trousseau, Murchison, Austin Flint, Currie, H. C. Wood, Ringer, Reynolds, Ziemssen, Bartholow, Brunton, Hare, Baruch, Pepper, Loomis, and others.

"From this hasty and incomplete survey a number of lessons may be learned. Before this generation the expectant method held pre-eminence, its best exemplar being the observant and wise Watson. His writings are delightful, as he was blessed with the gift of commonsense. Chambers then draws special attention to the need of restoring function and supplying new bricks to the tumbling human temple. His teachings seem to reach the English-speaking physicians, but the continental physicians are working by contraries, cold baths are revived and statistics pile up. Specifics are found, and the diseases are shortened by this and that. As each new remedy lessened the mortality by from five to twenty per cent. it would seem that away back, more than one hundred per cent. must have died. Bloodletting and depleting measures held out longer in France. Excessive alcoholic stimulation gave place to occasional stimulation—twenty-five to thirty ounces a day falls to four or five ounces. With the certainty of bacterial origin for many diseases, antiseptics are tried in typhoid fever, but mostly fail. Diet remains fluid, as the enfeebled stomach cannot digest solids, rather than for fear of doing the intestine harm. Antipyretic drugs begin to be abandoned as weakening the heart, and fewer physicians fight fever as such. The present state of therapeutics, therefore, is, in the words of Wood, 'a mixture of science and empiricism.'"

DR. WILLIAM H. DRAPER thought the changes in treatment mentioned to night were not really as great as one might at first suppose. If we should systematize the different forms of fever we would find that, while the means had been variable, the principles had been few. Instability was rather an opprobrious term, yet he would venture to say that at no time in the history of therapeutics had stability been a desirable quality. Instability in therapeutics meant progress in medical science.

Limiting his remarks to pneumonia and typhoid fever, it was certainly within the recollection of some that pneumonia was formerly treated as a pure inflammatory disease, and on that basis it was treated antiphlogistically. It was bled, it was purged, it was sweated. Typhoid fever was looked upon as a disease in which the intestinal lesion was the essential element, and this lesion was treated, and treated for the most part with remedies which were intended to drive the disease away from this part of the body.

The great revolution in therapeutics which had come within his time was a revolution which was dependent upon an entirely different view of the pathology of these two diseases; upon the view that they were essential fevers which ran their course in definite periods. The effort was then no longer made to exorcise these diseases by violent remedies. They were treated symptomatically by the majority of the profession. Still, empiricism had held sway more or less, and many remedies had been brought forward as alleged specifics. So far as his personal observation had extended, however, he had seen no craving after a specific method of treating either pneumonia or typhoid fever. He believed they were much more successfully treated now than thirty years ago, for the reason that they were allowed to run their course without serious interruption or serious interference which came from the administration of experimental therapeusis. Nor did Dr. Draper believe that within our time we would see any specific for either affection. The introduction of the germ theory did not seem to offer at the present time any hope of great improvement in therapeusis based on that theory. Yet, he said, if ever a specific should be discovered it would, of course, be based on the destruction of the germ which produced the disease. At present there was none known which would not first destroy the patient.

With regard to the diet, he could not say that within his time he had seen any very great revolution in the feeding of these two diseases. A revolution took place at an earlier time than when he began to practise medicine. He supposed we could date the period of feeding fevers from the time of Graves and Stokes. The pendulum then swung too far in that direction, and Murchison, he thought, was right, when he said we were overfeeding fevers instead of feeding them in a scientific and rational way. The introduction of milk in sustaining patients with fever was a very great improvement upon beef-tea.

He agreed with Dr. Flint that beef-tea was worthless except as a means of supplying the system with fluid. Again, if there was any kind of food which was not well borne in fevers, it was, he thought, albuminoids. It was this property which made even milk disagree to some extent. But febrile patients digested fats, they digested the cream of milk well, and all the properties except the albuminoids. It seemed to him that the method which had seen introduced by Dr. Roach, of Boston, for feeding modified milk according to a certain formula, would prove very valuable.

In his early experience they gave at Bellevue Hospital large quantities of alcohol to fever patients, and he remembered that Dr. McCready could never reconcile himself to that he regarded as simply a waste of very good whiskey. They then frequently gave a pint or a pint and a half of whiskey to a patient with typhus or typhoid fever. As feeding was overdone, so was stimulation. He believed the rules laid down by Murchison with regard to the use of stimulants were good ones, but he did not believe they were better than Stokes's, who said that so long as alcohol diminished the frequency and improved the force of the pulse, so long as it caused a dry tongue to become more moist, so long as it diminished subsultus and quieted delirium, so long it was doing good. But when it increased the frequency of the pulse, and made it quick and small; when it increased the dryness of the tongue, when it increased the cerebral excitement, and when it increased the subsultus tendinus, then it was doing mischief.

Hopeful of Inoculation Treatment.—DR. A. A. SMITH had been requested to discuss changes which had taken place with regard to cardiac stimulants, but he wished to say, first, that he had more hope of shortening typhoid and pneumonia, or fevers, than it seemed Dr. Draper had. Not, however, in the line mentioned, of destroying the germs, but rather by inoculation of products of the disease from other patients.

Of the remedies which had best held a place in the

treatment of these diseases, it seemed to him that alcohol was one. As Dr. Draper had said, it was once given in very large quantities, as much as the patient could hold. It was probably given as often to-day as formerly, but not in so large quantities.

The next most common tonic or stimulant, especially in pneumonia, was opium. It was more especially used where there was pain of pleurisy associated with the pneumonia. It also seemed to Dr. Smith to be useful in relieving cough and in oxygenizing the blood when not continued too long and in too large quantity.

Under the instructions of the visiting physicians years ago, he had frequently given forty to sixty grains of quinine at the beginning of pneumonia. It was supposed to sustain the nervous system, to reduce the temperature, and to shorten the disease. As he recalled cases of pneumonia in which sixty to eighty grains of quinine were given a day he thought the disease was really shortened. But only by shortening the life of the patient. Many patients recovered, but in spite of the quinine. He thought it would be a great rarity to find a physician in the city who gave as much as fifty or sixty grains of quinine a day to a patient with pneumonia. It was, however, still given, but in small doses, six or eight grains a day, which produced only the tonic and stimulating effects of the drug.

The Ammonia Preparations.—Twenty years ago these occupied a prominent place among the tonics and stimulants, especially in pneumonia. Following the lead of Richardson, the carbonate or muriate of ammonia was given with a view to lessening the liability to cardiac thrombi. Dr. Smith had been impressed by their depressing effect upon digestion. Aromatic spirits of ammonia, however, was well borne by the digestive system, and if there was any virtue in the ammonia preparations this was the best one.

Digitalis.—No agent had been discussed more hotly from a personal standpoint than this one. It was much used twenty years ago, held its ground many years, then lost a good deal, and again had come to be used considerably, but less than during the earlier period. The same thing might be said of strophanthus and convallaria. Convallaria flashed up, was advocated extensively, then passed by. Strophanthus had held its place better than convallaria but not so well as digitalis. There was a doubt in the minds of many even with regard to the propriety of using digitalis in pneumonia.

Strychnia.—Strychnia was practically not in use twenty years ago, yet to-day it was recognized as one of the best, if not the best, cardiac and nerve tonics in both pneumonia and typhoid fever. In the opinion of many caffeine should take an important place. In certain conditions it has been used with a great deal of success. Glonoin had been used, but there was much diversity of opinion as to its value. Dr. Smith was inclined to believe that it would hold a place in pneumonia.

Baths.—The enthusiastic advocates of baths claimed that there was much less need for cardiac tonics and stimulants since their introduction, and Dr. Smith agreed with this view. He thought ether and camphor had not held their place. If oxygen were a tonic and stimulant, it was so only secondarily. Twenty years ago it was used quite extensively; then it seemed to have fallen into disuse, but it seemed to be more growing in favor again, and had more than held its place.

The Present Treatment of Pneumonia and Typhoid Fever.—Dr. George L. Peabody thought the treatment of pneumonia to day had come to be entirely a matter of intelligent expectant and symptomatic treatment. There was no recognized routine treatment which could be applied to all, or even any considerable number of cases of croupous pneumonia. For the relief of cough, we were all compelled in certain cases to resort to some active remedy, and he had himself frequently found it necessary to use a few drops of chloroform inhaled from a wide mouthed bottle covered with cotton. Used in that way not enough chloroform was inhaled to do harm. Steam was also useful in relieving cough and loosening material in the upper air passages.

Opium.—It was frequently necessary to relieve the pain of pleurisy connected with the pneumonia. He had often been struck by the prejudice which existed against opium or any of its alkaloids in pneumonia, the old idea being that it depressed the respiratory centre. He believed, however, that we were amply justified in using say, one-sixth of a grain of morphine subcutaneously, for the relief of pain, and frequently it was the only means of relief, although occasionally hot water or ice to the surface would answer. Hot and cold water or ice acted in the same way, by depriving the affected part of some of its blood supply. For the relief of the insomnia of pneumonia, he preferred sulphonal and like agents to opium or chloral.

To Relieve Dyspnœa.—To relieve dyspnœa due to congestion of the venous system, Dr. Peabody had much faith in the temporary removal of blood from the centre of irritation. It could be accomplished by placing a ligature about an extremity, thereby shutting off several pounds of blood from the general circulation, which might be continued an hour or an hour and a half. Of course if the dyspnœa were due to extensive involvement of the lungs, the ligature might fail to relieve it. Oxygen would then be of value. But he thought it was a mistake to suppose that oxygen would be of value where there was no obstacle to the entrance of air. Stimulants would relieve dyspnœa to a certain extent, particularly where it was due to overdistention of the right ventricle and right auricle. He would rank caffeine high among stimulants under those conditions. It was important to give a good preparation; the so-called citrates were inert. None was better than the caffeine itself, which, being insoluble in water and the fluids of the mouth, could be rendered soluble by the doctor himself giving it in citric acid, thus making his own citrate of caffeine.

As to antipyretics, he was personally a believer in cold baths in croupous pneumonia, used by the Brandt method as in typhoid fever. Give the bath once in three hours, temperature of 65° F. If the patient's temperature rose above 102.5° or 103° F., friction was useful. Antypyretic drugs were not to be relied upon, especially if the temperature were high. If the patient were robust, a soothing dose of antipyrine could be given, but not enough to reduce the temperature lest it produce a toxic effect upon the heart. Simple nutritious food; milk with each meal. Digitalis was the best stimulant. We now had a praiseworthy preparation of digitalin. Formerly it was an inert powder. He still used the French dosometric treatment, aconitin, digitalis, and arsenite of strychnia, modifying the combination according to the case, but had less faith in its value than formerly.

Drugs in Typhoid Fever.—As to drugs in typhoid fever, he thought that according to modern views the fewer used the better. He believed that the cold bath, according to the Brandt method, with friction in the bath, was rapidly replacing all other methods, and in his opinion it was the best. He still has some hope for the antiseptic method, not in killing the bacteria, but in counteracting the poisons to which they gave rise.

The Chairman named different kinds of treatment and called for a raising of the hand by those who still employed them.

Remedies which have Stood the Test of Time.—Dr. Simon Baruch thought that if the value of remedies was to be judged of by the length of time they had been in use, those of a hygienic character certainly took the first place. Baths and feeding as remedies for disease dated back as far at least as Hippocrates.

Lubricant for Catheters.—Castor-oil is an excellent material for this purpose. It is non-irritating and tenacious. It should always be applied warm, and the bottle containing it should be frequently washed with alcohol. It can be used for silk and rubber catheters alike. —Dr. J. M. Kitchen.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, November 27, 1893.

WILLIAM STEVENS, M.D., AFTERWARD H. D. CHAPIN, M.D., IN THE CHAIR

The Medical Directory.—DR. DANIEL LEWIS read his fifth annual report as editor of the Medical Directory. To the last volume had been added names of practitioners in the counties of Kings and Westchester. Those members whose names had been omitted should communicate with the treasurer. The total receipts had been $1,812; expenditures, $1,686. Including uncollected bills, the balance to the credit of the society was $393.

The society accorded Dr. Lewis a vote of thanks for his painstaking task in editing the directory.

Report of the Committee on the Practice of Midwifery.—DR. EDWARD A. AYERS, chairman of the committee consisting of Drs. Ayers, Baruch, Jones, Collyer, and Drayton, appointed at the March meeting to report upon the regulation of midwifery, read the report.

DR. DANIEL LEWIS moved that the report be received and referred to the comitia minora with power.

DR. PIFFARD thought that the proposed amendments should not be presented before the Legislature until they had received the indorsement of the State Medical Society and approval of the State Board of Medical Examiners and of the Board of Regents. He offered an amendment to that effect, which was adopted.

Address of the Retiring President.—DR. WILLIAM STEVENS, retiring president, read a brief address, reviewing some of the work done by the society during the year, recommending to the consideration of the members the Society for the Relief of Widows and Orphans of Medical Men, and expressing thanks for the courtesy which had been extended him during his term of office.

Address of the President Elect.—In the absence of Dr. Powell, President-elect, the Vice-President, DR. H. D. CHAPIN, read his address. In it he referred to certain abuses in medical practice, most prominent among which was the treatment at dispensaries and hospitals of persons who were able to consult a physician at his private office. A most flagrant violation of the charity act had been committed by the Board of Health when it had vaccinated free the members of the Board of Trade and other prosperous business people. A corporation lawyer exacted the highest fee commensurate with the interests involved. Why should the physician take a different course? It is also suggested that there should be legislation providing for the summing up by experts before the court or jury of testimony of a medical character. Such a system of expert testimony would inspire confidence and respect, whereas the present one had an effect quite the opposite. It was also recommended that any proposed medical legislation should first be submitted to the consideration of the comitia minora before being acted upon by the society. There should be a standing committee on legislation. The address contained a quotation from a recent editorial in the MEDICAL RECORD regarding the New York Infant Asylum affair, and surprise was expressed that physicians could be so short-sighted as to range themselves upon opposite sides of this question. The entire profession should stand together in repelling such injustice and discourtesy shown its members.

On motion the recommendations and suggestions contained in the President's address were referred to the comitia minora with instructions to report at the next meeting.

Bureau of Nurses.—The comitia minora reported as follows: That the question of the appointment of a committee to establish a Nurses' Bureau shall be referred back to the society with the recommendation that a committee to confer with the Academy of Medicine with regard to the establishment of such a bureau shall be appointed in its place. The report was accepted.

Notes on the Modification of Cow's Milk for Infant Feeding.—DR. HENRY D. CHAPIN gave a *résumé* of the method of modifying cow's milk as suggested several years ago by Dr. Roach, of Boston, and now being carried out at the Walker Gordon Laboratory in this city, a rather full description of which was given in the MEDICAL RECORD a short time ago by Dr. Northrup. Dr. Chapin had tried modified cow's milk for infant feeding in a number of cases, with almost uniform success.

DR JOSEPH E. WINTERS had used modified cow's milk a great deal. He had never had to change it to wet nurse. He had tried it in cases of premature birth with success, also in disease, and knew no reason why it should not always succeed if any kind of food would.

A Newly Described Skin Disease.—DR. H. G. PIFFARD said that in the February number of the *British Journal of Dermatology*, 1892, Dr. Thomas Savill described a skin disease which resembled, in many respects, an eczema, but which was afterward found to be much more serious in character and due to a specific diplococcus. It occurred in man and animals. No case having been reported in this country, Dr. Piffard had requested illustrations of Dr. Savill's case, and having received them he wished to show them to the Society. The colored plates of the pathological condition were the best he had ever seen.

Some Observations upon the Action and Value of Hyoscyamin in Nervous and Mental Diseases; Personal Experiment with the Drug.—DR. WILLIAM SPRATLING read the paper. He had been connected for five years past with a State institution for the insane in which were admitted about one hundred acute cases annually, and had had considerable opportunity for observing the effects of hyoscyamin or hyoscin in mental and nervous diseases, especially during the first part of that period. He had many times given one-tenth of a grain of sulphate of hyoscyamin, sometimes one eighth of a grain, but this was before he had had much experience with it. A case which had strongly impressed upon him the possibility of serious consequences of giving large doses was that of a vigorous young Irishwoman who received one-eighth of a grain every eight hours until several doses had been administered, in order to control her maniacal state. Physical restraint was prohibited. She died on the tenth day, and the condition of the blood and circulatory system led him to believe that the poisonous action of the drug had been a potent factor in bringing about the fatal issue.

The reports upon the hypnotic effects of hyoscyamin and hyoscin had been very contradictory. Dr. Spratling believed that their hypnotic influence was only apparent, being due solely to the motor paralysis which they produced. The patients did not sleep, did not obtain mental rest, but were left in the same state of mental excitement after the bodily lassitude or paralysis had passed away.

The author then described the effect upon himself of a hypodermic injection of one-fifteenth of a grain of hyoscyamin into the arm. The first effect was a fulness of the head, objects presented a hazy outline, then he became jolly, laughed immoderately; after many fruitless efforts, succeeded in getting into bed. Pulse and respiration were increased. Pinching his right leg as hard as he could produced only the sensation of pressure by a blunt object. Ten minutes after receiving the drug motor paralysis became complete, commencing with the lower extremities and proceeding upward. Grosser movements suffered first. There was a furry feeling of the mouth; inability to speak; motor and sensory paralysis lasted about four hours, yet at no time did he sleep, at no time become unconscious, but remained for some time in a condition of jolly delirium. Later, however, the delirium became painful, then horrible; then a state of double consciousness set in, in which he suffered from delusions and wild fancies, but still was conscious of his situation. Eight hours after taking the drug all evidence of motor disturbance had disappeared; sensory disturb-

ance left him later. At no time did he sleep. The drug tended to dry up the secretions. Dr. Spratling thought its action went to confirm Dr. Dana's recent experiments which pointed to common centres for motion and sensation. He thought the drug admissible only in chronic diseases of the nervous system.

Dr. Williams had found hyoscyamin and hyoscin hypnotic in small doses, and useful when thus administered in some cases of acute mania, as well as in chronic affections.

SCARLET FEVER—ITS LOCAL LESION—PATHOLOGICAL SOCIETY—STREPTOCOCCUS PNEUMONIÆ IN CEREBRO-SPINAL MENINGITIS—ROYAL MEDICAL AND CHIRURGICAL SOCIETY—OPERATIONS WITHOUT ANÆSTHESIA—USE AND ABUSE OF ANÆSTHETICS—CHRIST'S HOSPITAL—GENERAL MEDICAL COUNCIL MEETING—THE PHARMACOPŒIA—THE COLLEGES—PURIFYING THE REGISTER—MEDICAL SOCIETIES—EXHIBITION OF LIVING PATIENTS—THE CHANGES THAT OCCUR IN THE URINE IN MYXŒDEMA DURING THE THYROID TREATMENT.

London, November 25, 1893.

Scarlet fever has been so prevalent that a paper on the local lesion read at the last meeting of the Pathological Society (21st) may claim the interest of being timely. The author, Dr. W. Dowson, having pointed out that although endemic in certain areas a very large proportion of the population escaped, all but about five per cent., and the disease was infrequent after the age of sixteen. Searching for a reason of this, he was led to think that the primary local lesion is in the tonsils and cervical lymphatics, general infection occurring through the absorption of toxines. Cases of sore throat and fever occurring during an epidemic he regarded as mild scarlet fever. When primary infection took place through a wound the throat might escape and differences occur according to the tissues involved, hence the variations in surgical and puerperal cases. Further it was suggested that acquired immunity may be merely local, the changes in the tonsil induced by one attack being of a fibrous nature and so preventing the entrance of the toxine afterward. So again the natural development of the tonsil at puberty and over thirty years still further limits the chance of infection. He compared the affection of the tonsils and cervical glands to the chancre and bubo of syphilis, and the intestinal ulcer and enlarged glands of typhoid fever.

Dr. Cayley opposed the theory, and had no doubt that the poison was contained in the skin, and the epidermis continued infective long after the throat was well. More over he had seen many cases in which there was no sore throat, but the acquired immunity was just the same as in those in which the tonsils were much damaged. Dr. Goodall corroborated Dr. Cayley, and remarked that severe nephritis and desquamation were common after the mildest cases.

Mr. Shattock pointed out that younger animals were more susceptible to microbes than older ones, instancing the white rat, which is well known to be susceptible to anthrax when young, while the adult is not. Dr. Dowson in reply, said very young infants were exempt from tonsillar lesion, as they suckled and so the throat was not likely to be wounded by sharp particles of food.

Dr. Kanthack then read a communication on the streptococcus pneumoniæ in cerebro spinal meningitis, and showed the cultures from a case at St. Bartholomew's Hospital which was not complicated with pneumonia or other lesion. Inoculation into mice killed them rapidly, and cultures from the heart's blood of these mice grow more rapidly, assuming true streptococcus form and losing their virulence toward mice. The pneumococcus shown by Dr. Kanthack approaches the streptococcus pyogenes form. But some thirty other varieties have been described!

At the meeting of the Royal Medical and Chirurgical Society, after the question of the Presidency, which I have already noticed, Mr. Keetley read a paper on operations without anæsthesia. This was not an account of the terrors of surgery in olden times but rather a dissuasive from the abuse of anæsthetics and a suggestion that these agents are too commonly employed for minor operations. The author reminded the audience that on the discovery of general anæsthesia its dangers were not at first realized, and that now both surgeons and the public seem to have forgotten what can be done without it. Mr. Keetley had operated in a case of thyroid tumor by the aid of nominal local anæsthesia, and he thought that minute quantities of cocaine acted through the imagination and that some operations, especially in the abdomen, reported as under cocaine, were really of this kind, as also were many under hypnotic influence. He proposed, therefore, that general anæsthesia should not be induced in a strangulated hernia, in the old or debilitated, in colotomy and similar cases when the proceedings can be planned beforehand, in tapping, aspirating, sounding, or even in laparotomy by a small incision for exploration, or perhaps for evacuation of fluid (or even of a simple non-adherent cyst). He considered nitrous oxide appropriate for not a few cases in which ether or chloroform is often given, as simple incisions of any length, encapsuled tumors of any size, if superficial, for refracturing mal-united bones, etc.

Mr. Power related some of his experience in the pre-anæsthetic era when such an operation as enucleation of the globe was very serious. Now in eye operations cocaine locally, five or ten per cent., is sufficient for all, except, perhaps enucleation or abscission. Dentists came most directly in contact with acute pain and he mentioned a personal experience of exhaustion and depression after abstraction of a molar. On the other hand he was once suffering from pleurisy and surprised that the passage of a trocar through his chest wall was painless. Other speakers to some extent supported Mr. Keetley as to many cases, but it was suggested that chloroform was generally necessary for children for operations about the rectum, and some held that only in a very small minority of cases could general anæsthesia be avoided. Others thought we should not resort to general when local anæsthesia could serve—that the latter might be used in strangulated hernia, especially if the patient was aged or exhausted. So, too, in tracheotomy for diphtheria, in advanced phthisis, and in goitre pressing on the trachea local anæsthesia was often sufficient. In reply, Mr. Keetley admitted the use of chloroform in children except for an operation such as that for imperforate anus in early infancy. He said, too, that the Swiss surgeons had generally discarded anæsthetics for operations on goitres.

In reference to the question thus brought forward, I may express a belief that in some quarters general anæsthesia has certainly been too frequently resorted to when local anæsthesia would have done all required. It is curious, too, how little the ether spray has been used by some. It is harmless and effectual for many cases. I have seen it much used for tracheotomy and goitre, and with complete success. It is admirably adapted for incisions, after which a very weak solution of cocaine may be used to supplement it for deeper work, such as the enucleation of encapsuled tumors.

Last month scarlet fever broke out in the Blue Coat School. The scholars were accordingly dispersed and a sanitary inspection of the premises undertaken. This disclosed a most primitive state of the arrangements, and the City Medical Officer of Health has reported, that with a full sense of his responsibility in interfering with such an ancient and important institution as Christ's Hospital (to use its official name), he cannot avoid the conclusion that nothing short of an entire reconstruction of the drainage would suffice to render the school fit for its purpose. Steps have therefore been taken to carry out his recommendation.

London, December 1, 1893.

The General Medical Council met on Tuesday, and is still sitting. Professor Gairdner, the new member for Glasgow University, was received with unusual demonstrations of pleasure. Sir R. Quain delivered his presidential address, indicating the various subjects that demanded the attention of the Council. This address would be interesting if it were not rendered useless by the fact that each subject it touches upon has to be subsequently discussed. It must be strange if a body of learned and distinguished men require a recapitulation of the business of the week before they can begin it. There are so many complaints of the limited time of the Council that perhaps a saving might be effected by the omission of the address. Perhaps the most interesting subject of discussion on your side the Atlantic will be the approach toward an International Pharmacopœia. The medical authorities of India and the colonies have been in communication with the Council as to their wants, and as a new edition of the British Pharmacopœia will be wanted in about a couple of years, it will not improbably be adopted for the Empire as far as the committee can manage. I wonder if America will some day join in this work so as to have a codex for the English-speaking world.

The Dublin College of Physicians claimed to compete with its London sister in granting a complete diploma, but as it never has examined in surgery, the Council referred it to the law courts for an interpretation of its charter.

Wednesday and Thursday were devoted by the Council to their judicial duties under the Penal clauses of the Acts. Certain persons' names were ordered to be erased from the Register. Condemnation of certain proceedings was expressed, and other cases were remitted to the law officers of the Council to prosecute.

A number of returns respecting examinations and other documents came under the consideration of the Council.

The exhibition of living specimens of disease gains rather than loses in favor, and "clinical evenings" at the societies often attract larger audiences than elaborate papers. The last meetings of the Medical Society and the Clinical Society were thus occupied, and at some of the other societies there have been a considerable number of exhibits of this kind.

At the Medical Society Dr. Beevor showed a case which he considered to be syringo-myelia. It was in a young woman, and dated from an illness six years ago, after which numbness of one arm (right) came on, and gradually extended. The numbness is now more marked on the right than the left side. Reflexes exaggerated. Though large tracts of the skin are insensible to pain, the tactile sensibility is preserved.

Mr. Lunn brought a patient who at first glance seemed a child, but was a woman of twenty-six. She was a cretin, idiotic, but had become comparatively intelligent under treatment by thyroids. The same surgeon showed a hæmatoma which succeeded an operation for popliteal aneurism. It is non pulsatile, and he supposed it to arise from the filling of the sac after the ligatures had been applied. If it does not subside with rest and pressure in two or three months, it is proposed to cut down and turn out the clots. Occlusion of the superior vena cava is a nice diagnosis, but Sir Hugh Beevor showed a case which he ventured thus to describe. The cutaneous veins of the trunk are so dilated that there is evidently some obstruction. The condition was noticed some fifteen years ago. Dr. F. Roberts remarked that he once saw a man whose only symptom was intense cyanosis, and at the post-mortem the cava was found obstructed by a fibrous band. He also mentioned a case in which an aortic aneurism burst into the vena cava, setting up such a medley of sounds that a medical man hastily summoned could not account for them—and no wonder.

Mr. H. Fenwick showed a man from whom he had removed a hydatid cyst from the bladder by supra-pubic incision. Mr. Shield mentioned a case admitted for what was supposed to be ordinary retention, but the man passed a small hydatid cyst *per urethram*. The bladder was then emptied, but a tumor remained, which was removed through the perineum. Another case was mentioned by Mr. Ballance, admitted for retention, and a cyst discovered. This was aspirated above the pubis and the patient recovered.

Mr. Ballance also showed a young man aged twenty who had been operated on in September last, at St. Thomas's Hospital, for lateral sinus pyæmia, with rapid recovery. Mr. Watson Cheyne brought again the case he showed last March, of skin grafting for lupus after excision. The result continues good. Dr. Eddowes brought a girl with lichen pilaris symmetrically developed on both legs, and Dr. Pasteur a woman of thirty-two with numerous lines on various parts of the body resembling the lineæ albicantes that follow pregnancy.

Half a dozen cases of pseudo hypertrophic paralysis are not often seen together, but an opportunity was afforded at the Clinical Society, on the 24th, of seeing and comparing that number. Four of these patients were of the same family, under the care of Dr. James Taylor, who showed two of them three years ago, and now brought them again that the progress of the disease might be seen together with the other two. The oldest of the four was twenty-five, and had been affected from the age of eighteen. Two cases exhibited by Dr. F. Hawkins were children of eight and eleven, both belonging to a family of five, the other three not being affected.

A case of osteo arthritis with fibrous nodules over several joints was shown by Dr. Newton Pitt.

Two cases of so called idiopathic sclerosis were brought by Dr. Mott. One, a woman aged thirty, who was seized four days after delivery with numbness of the leg and hand, followed by paresis. Her speech was also affected, and Dr. Mott supposed there was thrombosis of the veins in the leg area leading to the longitudinal sinus. The other case was a man aged thirty-four, with multiple toxic neuritis. He had been admitted with swelling of the right ankle, pyrexia, and pains in the limbs. Soon after blood appeared in the urine and stools, giving rise to a suspicion of typhoid. Next came a rash on the right side, which was followed by paralysis of the same side. The case was then thought to be one of cerebral thrombosis.

Dr. Ord and Mr. E. White then gave an account of some observations they had made in the changes occurring in the urine of a patient with myxœdema while treated by thyroid glands of the sheep. For more than a week before commencing, the diet was carefully analyzed and the quantity registered, and comparisons made with analyses of the urine as to total solids, ash, chlorides, nitrogen, urea, and phosphoric acid. During treatment, the same diet being employed, these investigations were continued. The results showed greatly increased excretion of nitrogen, chiefly as urea, during the use of the thyroids. Very slight increase of chlorides. There was an increase in the quantity of urine, a rise of bodily temperature, and loss of weight. The physical and mental condition underwent rapid improvement, almost amounting to a cure. These observations seem to afford some means of estimating the altered metabolism which succeeds the use of the thyroids. Further experiments will no doubt be made, and I would suggest over a longer period prior to treatment, if only as to urea; for it seems as if the excretion of this body was scarcely equal to the amount that should occur in proportion to the nitrogen in the diet, but that as soon as the thyroids were exhibited an excessive excretion was set up.

Ichthyol.—This remedy may be used hypodermatically (three centigrammes in one gramme of distilled water). Good results have been obtained by injecting it about the vesicles in zona with intercostal neuralgia. The remedy has a certain analgesic power.

A CONTRIBUTION ON THE ORIGIN OF THE NON-RESTRAINT SYSTEM IN THE TREATMENT OF THE INSANE.

To the Editor of the Medical Record.

Sir: The non restraint system was advocated in Germany long before Dr. Gardner Hill and Dr. Charlesworth inaugurated it in the Lincoln Asylum. In evidence of this assertion I beg to call attention to the following extract from a work published in Germany in 1833.

"In mental and emotional diseases . . . an appropriate psychical behavior toward the patient on the part of those about him and of the physician must be scrupulously observed by way of an auxiliary mental regimen. To furious mania we must oppose calm intrepidity and cool, firm resolution; to doleful querulous lamentation, a mute display of commiseration in looks and gestures; to senseless chattering, a silence not wholly inattentive; to disgusting and abominable conduct, and to conversation of a similar character, total inattention. We must endeavor to prevent the destruction and injury of surrounding objects without reproaching the patient for his acts, and everything must be arranged in such a way that the necessity for any corporal punishments and tortures whatever may be avoided."

In a foot-note the author adds: "It is impossible not to marvel at the hard-heartedness and indiscretion of the medical men in many establishments for patients of this kind not only in England but also in Germany, who . . . content themselves with torturing these most pitiable of all human beings with the most violent blows and other painful torments. By this unconscientious and revolting procedure they debase themselves beneath the level of turnkeys in a house of correction."

In this extract non-restraint is clearly advocated, and in awarding the meed of praise the prior rights of this author should not be ignored.

A. B. Eadie.

Buffalo, N. Y.

THE OPPRESSIVELY AUTOCRATIC DOINGS OF THE LUNACY COMMISSION.

To the Editor of the Medical Record.

Sir: About two weeks ago there appeared in the New York *Tribune* an article on the Care of the Insane. That article was laudatory of the State Commission in Lunacy, but was interspersed with what seemed to be authoritative statements made by certain members of that board; and while the main burden of the article related to questions of an economic nature, it was manifest that the plans and methods of the Commission contemplated an interference with the medical and even minor details of the management of the State Hospitals; hence, it assumes a professional interest.

While the writer is not in a situation to know the details of the plan adopted by the State Commissioners in their control of the Asylums, he has observed the current of events in our State institutions long enough not to accept at once a plea for a reduction of expenditures as paramount to other interests, or even as the real motive in all instances in which it is made. From the days of Æsop to the present time, to call attention to a probable error in another has occasionally been the means of withdrawing public attention from our own objects. The commissioners, as public officers, must not feel aggrieved if their own acts be watched and criticised as they profess to be watching and criticising those charged with the local management of the State Asylums.

It would seem that the object of the article referred to, and of certain paragraphs in the public press since seen by me, was to convey the idea that the commissioners were instituting certain reforms, and correcting certain abuses in these State institutions, not only in relation to fiscal affairs, but in what may be regarded as the moral and medical management of the unfortunate inmates. It may then be properly asked: "What reform or movement in advance has the Commission actually instituted?" That supplies should be economically purchased and carefully used is only a business proposition, but that the estimates for the expenditures for the asylums, for a certain month, have been "cut down" even to the extent of $55,000, is not necessarily a meritorious act, for injury may have resulted from the "economy," or even increased future expenditure. In these matters the officers of the several institutions are entitled to be heard as to the necessity for the articles named in their estimates, and no praise is due the commissioners until that evidence is submitted, as well as a detailed statement as to the items on which the saving was effected.

As a matter of fact, has this Commission instituted a single genuine reform in the care of the insane?

Those of us who have watched and studied the development of the asylums for the insane from prisons to hospitals, know how earnestly the matter had been considered and treated from apparently every possible standpoint, and we also know that the actual improvement in the care of the insane has come through asylum officers. Asylum reform began in the asylums, was conducted by the medical officers, and has not resulted from outside influences. Criticism of an individual superintendent, or asylum, by outside parties has constituted only eddies in the current of improvement which has been moving steadily on during the last fifty years. These criticisms served only to mark the progress, not to cause it. Conollyism was an ideal, the details of which required time and patient work before a general and useful application of its principles, and this work was given by the medical officers of asylums. It is eminently true that asylum methods have been reformed from within rather than from without.

The medical supervision of each State Hospital, containing on an average over one thousand patients, requires qualifications of a special and high order. If any of the State hospitals has a superintendent unfitted for his duties, the specific statement should be made and measures should be instituted to secure a change. This would certainly seem preferable to placing all the asylums practically under the control of non-resident officials, who deem it important to interfere in such matters as the use of tobacco, as has been done by the State commissioners. The State hospitals are not penal institutions, and it is apparent that such questions as the use or disuse of tobacco is a matter properly belonging to the local medical officers, and should not be settled by a disallowance of an estimate for that article. It is to be hoped that the public does not approve of such measures of economy, nor do we believe that the commissioners can justify their act on the plea that it is injurious to health; for the allowed list of articles includes such stimulants as tea and coffee. The use and the abuse of an article are distinct ideas. The present position of the resident medical officers of our State hospitals seems little better than that of clerks appointed to enforce the ideas of an autocratic board. Favorable opportunity for the exercise of individual talent by the eight superintendents in the State in the solution of problems in psychiatry is removed.

So far as can be judged by public acts, no true reform has been instituted br the State Commission in Lunacy. The effort to utilize the labor of the patients, as an economic factor in asylum management, is only new in the apparent purpose to render it compulsory, as in the prisons. "Sew and make your garments, or you shall not be clothed," would seem to be the edict. For a long time systematic work by a portion of the patients has been regarded as a curative and otherwise useful means of treatment, and doubtless it has been used as fully as was practicable for proper purposes. The time has hardly come—rather, is past—for using forcible measures to secure work from the inmates of our asylums which may yet be justified in our penal institutions.

Having no interest in this question aside from that

which belongs to every citizen of the State, except a pride in the noble professional and humanitarian work done in our State asylums by the medical officers, I can speak without bias from a partisan standpoint, and it is my sincere conviction that the present plan of State supervision is unwise. Though the present Commission may give a safe and even useful application of the law, enough has already been done by them to show that the plan is dangerous, in that it is susceptible of development into an autocratic control of persons who should be free to act, until it is shown that they are unfitted for their posts; when they should be removed instead of being restrained and controlled by the rules of the Board.

If the plea for honor through a useful lessening of expenditures is to be made, then by all means let us have the items by which the saving is secured, and let these items be criticised by the aid of the statements of those who made the estimates, after giving the reasons for asking the allowance.

Further, it does not seem that the moral influence of the Commission will be enhanced by such general statements as that a number of persons have been maintained at State expense by being improperly included in the "families" of asylum officers. If there has been fraud on the State it should be dealt with in a proper way, and not condoned by decreeing that it shall not continue. The interests are too important and delicate for such coarse methods.

Each citizen of the State must feel that this subject may have a personal importance, for there is always the liability to the occurrence of insanity in some friend or relative. Shall the care of that person be under hospital or prison methods?

My letter is written solely in what I deem to be the interests of truth and right, for I have neither a personal cause to defend nor an enemy to punish.

E. D. FERGUSON, M.D.

TROY, N. Y., December 9, 1893.

SHOULD WE TREAT IMPOTENCE?

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It seems to me that such sophistry as that contained in Dr. Waugh's answer to the question: "Should Impotence be Treated?" (MEDICAL RECORD, December 2d, p. 736) ought not to go unchallenged. The fear that our patients may not use their various organs to the best advantage morally is no reason why we should decline to heal their bodily infirmities. When a patient comes to me suffering with chronic gastritis, brought on by worshipping too ardently at the shrine of Bacchus, I do my best to restore his physical ailment, with a gratuitous lecture on Temperance, if I think it worth while. It is not the physician's business to felicitate his patient upon the loss of a physiological function, or *a priori* pass sentence upon his dejected, spirit-broken, and unsexed client for crimes yet to be committed. The physician should be a physician first, and a moralist afterward. I recall a case of vaginismus which came under the care of the late Professor J. Ford Prioleau, during my service in the Charleston City Hospital. The woman was a prostitute by profession, but Dr. Prioleau in speaking to the class of undergraduates before him said, that although the woman would probably resume her immoral mode of life if cured, that was no reason why he should decline to restore her, so far as he was able, to her normal condition. No one who knew Dr. Prioleau ever questioned his purity of mind or character. I think the views expressed by Dr. Waugh at variance with the objects of the medical profession, and should be repudiated.

Yours truly,

J. M. HAYS, M.D.

GREENSBORO, N. C.

Pertussis.—The severity of the paroxysms may be often relieved by using a drachm of hydrogen peroxide in a little glycerine and water four or five times daily.

New Instruments.

A CASE SHOWING HOW A LOST INTUBATION TUBE WAS POSITIVELY LOCATED BY MEANS OF AN ELECTRICAL SEARCHER.

BY J. MOUNT BLEYER, M.D.,

NEW YORK.

LARYNGOLOGIST TO THE WEST SIDE GERMAN CLINIC, ETC.

IN describing the electrical searcher devised by me for the location of intubation tubes that may have accidentally slipped down into the larynx or the air passages I desire also to give a brief report of a case in which such an accident happened, and in which I successfully located the lost tube with my electrical searcher after all other known means to do so had been ineffectually tried. It was the first time I lost control over a tube, in some five hundred and forty cases of intubation of the larynx, which I have had the good fortune to do within the period of six years. Nevertheless, such an accident may happen to me again, in fact it may happen to anybody who practices the operation of intubation.

Not long ago my colleague Dr. Derleth called me to see one of his patients, a little girl three years old, who was suffering from a severe case of stenosis of the larynx due to acute laryngitis, which had resisted the most vigorous treatment and had become very alarming.

Nothing that had been tried relieved the symptoms of gradually increasing dyspnœa, and we decided upon tubing the larynx. The tube ordinarily suitable for a child of that age was found upon introduction to be two sizes too small, perhaps on account of the distention of the larynx. Another, to all indications of the proper calibre, was introduced and immediately the dyspnœa became relieved. This tube was left in place four days, and as the child had made such a good recovery I decided to remove it. To my surprise on searching for the head of the tube with my finger I could discover no trace of it, although I readily mapped out the space of the larynx and could feel the vocal bands. There was but one inference to draw and that was that the tube had slipped down and was lodged somewhere below the vocal bands. The respiration was undisturbed and for a long time I was puzzled as to what had become of the tube, but from the tubular character of the inspiration I was led to believe that the tube was still in the vault of the larynx.

But there was nothing that the examination recalled to substantiate my suspicion until I probed with a metallic staff bent to a shape to accommodate its passage below the vocal bands.

To make doubly certain I next searched the bed-clothes and deferred further exploration until a large dose of castor-oil had been administered and its effect observed, so as to exclude the possibility of the tube having been swallowed and lodged in the intestinal canal. A free examination of the bowels revealed nothing of the tube.

Dr. F. S. Dennis was summoned, and the advisability of making an exploratory opening in the windpipe was discussed. Dr. Dennis advised against such an operation unless a positive diagnosis of the location of the tube was arrived at. At his direction the patient was removed to St. Vincent's Hospital, where the facilities for operation were better. All through the consultation I insisted upon the tubular breathing as being diagnostic of the position of the tube in the vault of the larynx under the vocal bands. While Dr. Dennis was inclined to agree with me he nevertheless refused to resort to operative measures until that point had been settled beyond peradventure, and it was then, taking thought of the metallic character of the obstruction, that the idea of the electrical searcher occurred to me, and I hurriedly proceeded to rig up the instrument which located the tube as I had insisted after the bullet probe searcher had been used, and which I shall now describe.

On the opposite page I append a rough sketch of my instrument, which will give you some ocular idea of its shape

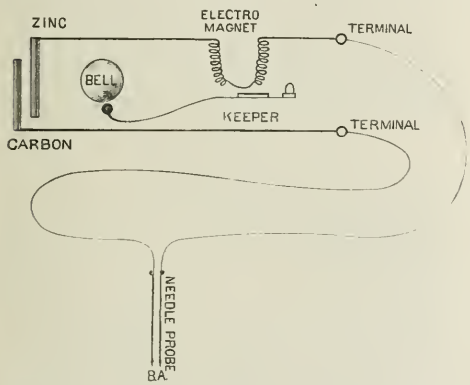
The apparatus consists of three parts, 1, the battery; 2, the alarm and bell; 3, the searcher, together with their accessories.

Perhaps it would be best to describe the parts in detail, by themselves.

The battery was an ordinary vulcanite cell, with zinc and carbon plate in a solution of sulphate of mercury, both plates being invested in separate compartments in the anterior portion of the cell, where they impinge upon platinum springs which are riveted to conductors on the outside of the cell from both positive and negative poles.

The zinc and carbon are interchangeable, it being immaterial which way the current travels through the apparatus. The poles of the battery come into contact with the conductor of the bell at the top of the partition, and it is necessary that the metallic surfaces should be clean, as any film of dirt or oxide would impede the passage of the current.

The Alarm.—This consists of brass strips or conductors mounted on an insulating bed of vulcanite which proceeds from the poles of the battery to the binding screws or terminals which stand on the partition to the right of the bell. One of these conductors on its route has the form of silk-covered wire wound many times around pieces of soft iron, which together form an electromagnet. It is on the immediate right of the bell. The



instrument electrically considered is thus far complete and may be tested by establishing communication between the two terminals or binding screws with a knife-blade or any other metallic conductor, thus completing the circuit. As the current passes the iron is magnetized. The keeper to which the hammer of the bell is attached is attracted, and a stroke is given to the bell. We may thus know, before using the apparatus, that the battery is in action and all metallic contacts clean and in reliable working order.

I now come to the description of the searcher, which is the surgical portion of the apparatus. It consists of two pointed steel needles, A and B, firmly fixed in an ivory handle from which they project about four inches. They are kept insulated from each other by a strip of vulcanite lying between them, while between the points and the handles the wires have a slender vulcanite tube passing over them which is screwed into a short length of tubing made of German silver, upon which is mounted a small shield. The tubes thus screwed together are free to slide to and fro about half an inch and may be pushed forward by slight pressure of the second finger upon the shield and thrown back by a spiral spring, which obtains purchase upon two screws inserted in the ivory handle through slots in the German-silver tube. It will be seen, after a few moments of study of the sketch which I have made, sacrificing artistic beauty to diagramatic simplicity, that the needle probe has the current laid on but broken at A and B (the point of the probe); it is now apparent that upon introducing the needle probe into the tissues, upon touching a metallic substance, such as the intubation tube, it will supply a bridge for the current to pass from A to B, thus throwing the keeper into action and ring the bell, signifying beyond doubt that the points of the needles had impigned upon a metallic body, in this case the intubation tube.

The Method of Using the Searcher.—The probe is handled precisely as one would hold a pen, in the right hand, and with the left the integument over the trachea is tightened and the needle points are thrust into the trachea between the cartilaginous rings.

It may be necessary to make several exploratory punctures before the obstruction is reached.

In the case upon which we operated, if I remember right, we received the signal from the bell upon the second puncture, which marked the exact location of the tube. Right here let me mention that I have devised also a probe searcher, consisting of a long flexible catheter with metallic points and sides, which may be used for the location of foreign metallic bodies through the mouth.

Immediately upon receiving the signal from the bell tracheotomy was performed low down, and the tube, which was found in the vault of the larynx directly under the points of the needle probe, as I suspected, was withdrawn.

While the operation, in every one of its stages so successful, had led us to hope for a happy result, nevertheless the patient died seventy-four hours afterward from pneumonia.

118 East Sixteenth Street.

The Value of Tropacocaine.—Dr. C. A. Veasey, of Philadelphia, says of this substance (*N. Y. Medical Journal*): "The palpebral fissure was somewhat enlarged, as is the case with cocaine, but at no time did I observe any ptosis. I have used it in some minor operations, but do not like it any better than the ordinary cocaine solutions; and as the price of the preparation is so high—being about forty cents a grain wholesale—it is hardly probable that it will come into general use. For removing foreign bodies from the cornea, or for making strong astringent or caustic applications to the cornea or conjunctiva, it is preferable to cocaine on account of its feeble and infrequent action upon the accommodation, thereby preventing the annoyance of a hazy vision for a time; and in cases of keratitis, when an anæsthetic must be employed, it is to be preferred, as it does not diminish to so great an extent the blood supply. For other purposes I have not found it superior to the cocaine hydrochloride in general use."

Malacine.—*Les Nouveaux Remèdes* for October contains an article relating to this new drug. Dr. A. Jacques, of Bâle, has made a study of the therapeutic and physiological action of malacine, and finds it an excel-

lent remedy in rheumatism and neuralgic affections. As an antipyretic it is superior to any other of the preparations of this series. It is especially suitable to protracted febrile conditions, where it is essential that the remedy shall not be depressing. It is derived from the salicylate of phenacetin. It appears in small crystals of a pale-yellowish color, insoluble in water, but soluble in warm alcohol. The stomach will retain the medicament when no other drug can be borne. It is particularly indicated in cases where the temperature is high and the heart much enfeebled. In rheumatism it can be given almost indiscriminately for a long period without any untoward results. In the treatment of habitual headache the remedy can be prescribed without regard to idiosyncrasies. The dose is from twenty to thirty grains, and the physiological effect continues for about six hours.

A Medical Society Report.—A British journal has published the following:

Royal Pimple Curing Society.

Dr. Makem-Pay, President, in the Chair.

Dr. Cutemout related the case of a patient who had for some years past suffered from a very painful and interesting complaint. Not having the notes of the case before him he was compelled to speak from memory; and unfortunately the symptoms had long since been forgotten. The etiology of the disease was very obscure, and he proposed to deal with this more fully on a subsequent occasion. As to treatment, he had found it necessary to employ a great number of remedies, and when last seen the patient reported himself as improving—he was unable to say under which particular treatment. He had since lost sight of the patient, and could not therefore say whether the improvement had been maintained. Dr. Swindem expressed the great interest he took in the case so clearly brought before the Society, and asked for further details, particularly as to whether the bowels were regular. Dr. MacAdamised said he had met with a similar case in his private practice, in the person of a wealthy American gentleman who, after having been treated by all the leading specialists of Europe and America, recovered in the course of three days in his private hospital at 24 Pignony Street, W. Mr. Herringfry proposed a vote of thanks to the author for his interesting paper.

The Woes of Infants.—There are few points on which the doctrine of the liberty of the subject is carried to such extremes as in regard to the treatment of infants. "Shall I not do as I will with mine own?" and what is more a woman's own than the baby she has borne? And so it happens that, under the cloak of mother's love and maternal responsibility, cruelty is done and crime committed which in no other relation of civilized life would be permitted for a moment. Every week we receive reports of inquests on infants who have been "done to death" by the indifference, the carelessness, the ignorance of mothers; and these do but represent the more flagrant cases—a mere percentage, it is to be feared, of the preventable infantile mortality of the country. The sour and fetid feeding-bottle; the carelessly cooked and improper food; the giving out to nurse to reckless people, whose only aim is to gain as much and spend as little as may be over the unfortunate hired-out infant; the dosing of the sickly, and therefore fretful, child with poisonous infants' preservatives; the final overlying during drunken slumber—all these are modes of torturing and killing infants, which are excused as due to ignorance and not to crime. These forms of child murder—done calmly, coldly, and with acquiescence, if not calculation—but rarely meet with punishment, while often earning the solid consolation of the insurance agent; and yet the poor woman who unexpectedly becomes a mother, and, aghast at the horror of her position, with brain blanched by hemorrhage, and with mind incapable of intent, throws her child, in an access of wild terror, into a ditch or down a privy, she, poor wretch, is held guilty of murder. Surely the parents who bring into the world child after child only to lose them by diarrhœa, marasmus, convulsions, rickets, and other diseases due to ignorance and neglect, are guilty in greater degree. It ought to be recognized that woman's work during the child-bearing period of her life is to look after her children, and that the proper way of doing so is to suckle them. To rear children artificially with safety requires more time and care than does mere suckling, but it is for the very sake of saving time and lessening care that nursing is neglected, and, in a large proportion of the cases, this is the root of children's ailments. We suppose it is idle to preach on this text, it has been done so often and with such small avail. Probably the cheapness of female labor is at the bottom of a great deal of the mischief. However slack the trades for men may be, there is almost always work for women if they will take the price, which they mostly do; and thus we see the absurd spectacle of women, in the intervals of bearing and burying a tribe of children, sewing, charing, washing, or going to the factory, besides keeping the house together, working for the purpose a daily sixteen hours, while the lords of creation are doing perhaps three days' work a week, or perhaps are out on strike for an eight hours' day. And yet women marry! Evidently we are suffering from a want of correlation between the evolution of man and the progress of what we are pleased to call civilization. New conditions require new men; whereas man still retains within him the instincts of the savage, which are sexual. The man of to-day ought not to marry untill he has reached a time of life when he has been able to put by for a home; and those who know how far man yet is from such perfection will recognize how many woes the babies of the future are likely still to bear.—*The Lancet.*

CHOLECYSTENTEROSTOMY BY MURPHY'S BUTTON.

CASES OF

I. CARCINOMA OF THE DUODENAL PAPILLA—OBSTRUCTIVE JAUNDICE—CHOLECYSTOTOMY—PANCREOTOMY.
II. PANCREATIC CYST FROM A CALCULUS—IMPACTION REMOVED BY MANIPULATION.

REPORTED BY ROBERT F. WEIR, M.D.,

PROFESSOR OF SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE following case, from the comparative rarity of the affection and from the unusual surgical incidents connected with it, warrants its presentation this evening to the Practitioner's Society.

A man, aged thirty-five, a laborer, and of a marked alcoholic habit, was admitted to the medical division of the New York Hospital, February 24, 1893, for the treatment of jaundice. During the eleven days he was under medical supervision and treatment he had four chills, with a temperature running up to 104° and 105° F., in the interim falling to 100° F. On March 7th he was transferred to the second surgical division of the Hospital for an exploratory operation. The history that he gave was that he had been perfectly well until seven weeks previously, when he noticed that he was becoming yellow and that he began to have chills every day or two, with sweating at night, and a decidedly and rapidly progressing weakness. He had never had an attack of jaundice before, nor had he had any paroxysm of hepatic colic.

About two and a half weeks ago, after spreeing for a week, he began to have pain over the region of the liver. This pain has been severe and constant since that time, and the jaundice has been steadily increasing. He has had no nausea or vomiting, no epistaxis or itching of the skin. His appetite has been very poor for the last week. The pulse has been regular, and the stools have been very light in color. On admission into the surgical ward his temperature was 101° F.; respiration, 20; pulse, 88. The liver was enormously distended, extending downward to within an inch and a half of the umbilicus. The edge of this organ was distinctly felt, but no abnormal irregularities were made out on it. The gall-bladder could not be distinguished. The spleen was enlarged, the abdomen was full, tense, and tympanitic in the flanks, and some tenderness existed in the hypogastrium. The patient was decidedly anæmic, though fairly nourished and in a tolerably good condition. The jaundice was very marked, and of a deep golden color. Urine acid, 1.016, slightly albuminous, and deeply stained by bile, which gave the reaction of bile pigment under testing. A few hyaline casts were also found.

It was evident that an obstruction existed in the gall-passages, probably in the common duct, but whether it was due to a concretion impacted there or to a neoplasm, could not be determined. The enlargement of the spleen, according to Naunyn, is not met with in neoplasms of these passages. This, however, is a point upon which I did not feel able, from personal experience, to place any clinical importance.

On March 8th, under ether anæsthesia, an incision parallel to, and two and a half inches below, the free border of the ribs on the right side, some five inches long, was made, opening first the peritoneal cavity at the outer edge of the rectus muscle. Through this opening the liver was found, as had been previously made out, very large, smooth, and of a very deep color. The gall-bladder was recognized to be quite distended, but deep in the abdominal cavity, and pushed from the parietes by the enlargement of the liver. The deeper part of the wound was enlarged outward through the abdominal muscles, the rectus on the inner side cut through partially, the lower edge of the wound drawn downward, and a good view of the liver and gall-bladder obtained. This latter could be traced beyond the cystic duct, but further it could not be recognized. The gall-bladder was then aspirated and some five or six ounces of light-green colored watery bile were withdrawn. The aspirator wound was then enlarged, and the finger introduced and carried to its full depth revealed nothing. An ordinary urethral sound, No. 12 in size, was then introduced and carried farther in beyond the cystic duct, but nothing was detected, nor could it or a smaller instrument with varying curves be passed to any depth along the common duct. This exploration of the gall-passages by a sound, as is well understood, is more frequently followed by disappointment than otherwise, though I have succeeded in several instances, after the removal of gall stones, in carrying the instrument into the duodenum and thus satisfied myself of the patency of the whole canal. In this instance, with the hand in the free abdominal cavity and the sound in the gall-bladder, it could not be felt within an inch or an inch and a half of the duodenum. It was there arrested, nor could the common duct beyond that point be recognized. Palpation of the duodenum itself, and the region wherein the common duct was supposed to be, or of the parts adjacent to the duct and intestine, gave no evidence of the presence of any stone or tumor.

In this examination, however, it was recognized that the pancreas was distended to about three times its normal size, being, I should say, over three inches in vertical diameter at its head, and the size of the wrist as it stretched off well beyond to the left of the median line. No nodules or undue hardness of this gland were made out, but at its head a soft fluctuating mass was recognized, from which, on the insertion of a hypodermic needle, a clear, fluid-like normal pancreatic secretion was extracted.

In the hope that the sound or bullet-probe introduced at this point might pass into the duct of the pancreas and either discover a possible obstruction calculus in this duct, or in the papilla of the ductus communis, a small incision was made into this pancreatic distention and from two to three ounces of clear, slightly opalescent fluid were evacuated.

The exploration conducted through this opening, however, revealed nothing of a calculous nature. Neither the probe nor small sound could be carried into the duodenum. The cavity of the pancreas into which the probe passed was about the size of a hen's egg. These explorations occupied considerable time, a part of which was due to the arrest of the free oozing that came from the pancreatic incision. The bleeding here, however, while obscuring the exploration, was very easily checked by a tampon introduced into the little wound. Though nothing of a calculous nature was felt by these explorations, nor by palpation through the duodenal walls, it was proposed, in order to make the exploration a thorough one, that the duodenum should next be opened. But the pa-

[1] Read at a meeting of the Practitioners' Society, November, 3, 1893.

tient's condition showed that further operative procedures could not be safely continued. A glass drainage-tube was, therefore, carried into the pancreatic cyst, or rather distended pancreatic duct, and between this and the pancreatic wound a portion of iodoform gauze was packed in so that hemorrhage was readily arrested. The incised gall-bladder, now flaccid, was sutured to the parietal peritoneum by a number of fine, black-silk sutures, and into the gall-bladder another glass drainage-tube was passed, to which was attached, as was also to the pancreatic tube, portions of rubber tubing, so that drainage from these two organs should be safely carried beyond the reach of the external wound. A strip of iodoform gauze was also carried outside the gall bladder, and the abdominal wound closed by deep and superficial sutures. The wound was then protected as much as possible by strips of gauze moistened with collodion for a considerable distance beyond the line of incision. Through the applied aseptic dressing were conducted the rubber tubes, the distal ends of which were placed in bottles partly filled with an antiseptic fluid.

The bile, of a more brownish color, flowed freely the first twenty four hours from the tube in the gall bladder, and it may be briefly stated that for seven days the discharge from the gall-bladder was extremely free, running from ten to twelve ounces daily. For three days following, *i.e.*, up to the tenth day, it began to diminish, and it finally fell to four ounces per diem. During the first day after the operation comparatively little fluid escaped from the pancreatic tube, or, at least, it was not recognized. After that time from four to six ounces a day es caped. Within the first forty-eight hours after the operation the patient suffered a great deal from hiccough, which demanded the free use of morphine to quiet it, but on the fourth day, suspecting that the pressure of the drainage-tube might occasion this difficulty, the tube was withdrawn from the pancreas, whereupon the hiccough ceased. No symptoms of peritonitis ensued, though the passage of the pancreatic fluid, of necessity, after the removal of the tube, ran through a considerable tract within the abdominal cavity. As the glass tube running into the pancreas was perforated throughout its entire length, it is fair to infer from the beginning that more or less pancreatic fluid must have been in contact with the peritoneal surface. This only supports what has been observed in experiments upon animals, not only in reference to the pancreatic fluid, but also in reference to the bile, that when in a normal condition such secretions are not infectious nor irritating to the peritoneal cavity.

I was conscious that in my operative attempts to relieve this patient I had so far increased his jeopardy by bring ing about the escape from his body of such a large amount of pancreatic secretion; but I hoped that, as he had for an unknown period of time—certainly several weeks—been already deprived by the obstruction of that secretion in its intestinal uses, its escape might not be of great moment to him, and possibly, as in openings in the duodenum where such secretions have escaped (though not totally, it must be admitted), so here the process of repair would, as in the intestine, gradually close the opening. Moreover, Senn [1] had on this point stated that complete obstruction of the pancreatic duct would be followed by glandular degeneration and arrest of the physiological function of the organ.

The patient did fairly well for a time under this great loss of two important secretions. His jaundice was rapidly disappearing, as was to be expected, when emaciation and a decided deterioration of strength began to show themselves. The stools still continued clay-colored and were found to contain large amounts of free fat. No chills had recurred, nor at any time had his temperature gone above 100° F. He took a tolerably good amount of nourishment. The color of the urine had improved and there was no reaction to the ordinary test for bile pigment. The examination, made several times of this pancreatic fluid by Professor W. Gilman Thompson, showed that the fluid possessed very remarkable digestive activity; that it emulsified fat, formed peptones from meat, and converted cooked and raw starch to sugar with great promptness. This deterioration of the patient's condition, after it began, advanced so rapidly that I felt that I was justified in making the attempt to conduct one or both of these secretions in some expeditious manner into the intestinal tract. I first, however, wished to know whether the bile-discharge contained pancreatic fluid or not. This was possible if the obstruction existed at the duodenal papilla and left free a communication between the pancreas in a reverse direction through the common duct to the gall-bladder and out from my drainage-tube. A specimen of this fluid was also examined at this date by Professor Thompson, with the report that it contained no pancreatic juice at all; that it digested cooked starch a little, and emulsified fat very little, but had no action on raw starch at all, nor did it form peptones. What feeble digestive power it had is often to be found in the bile. And he further says, if any trace of pancreatic juice were

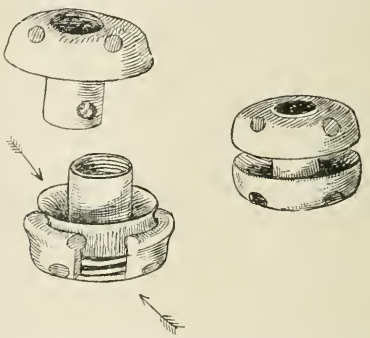

Fig. 1.—Murphy's Button. The button-like expansions are pushed into the incised intestine and gall-bladder, for example, and secured by a purse-string suture. The cylinder of the lower button passes within the upper one. Two teeth projecting inward in the lower cylinder catch in the threads inside the upper cylinder, when they are pushed together and prevent any separation of the compressed intestine and gall-bladder. The ring at the upper arrow indicates the ring that regulates this compression. The lower arrow points to a gap left to better demonstrate the regulating ring.

present, it would be more active. Had pancreatic juice been present a very simple communication could be established with the intestine and in a very rapid manner by employing the device suggested by Dr. Murphy,[1] of Chicago, and which I now show.

Not finding this secretion in the biliary discharge it was felt that the surgical procedures would demand either that the establishment of a fistula between the intestine and the pancreas should be made, if possible, or that the opening in the pancreas should be closed by firmly applied sutures and a solid tamponade. The practicability of establishing a pancreatico intestinal fistula was based only upon the fact that quite a large cyst-like dilatation of the common pancreatic duct was found at the first operation and of a size sufficient to admit one end of the Murphy button, when the other being placed in the opening of the adjacent intestine, the two could be forced together and the fistula rapidly completed.

In this judgment my colleague, Dr. Frank Hartley, concurred. On the tenth day the patient's condition was one of considerable weakness, but with a pulse of 92, and temperature 99½° F. Under ether the abdominal wound was opened, the recent adhesions separated, and the opening into the pancreas rapidly reached. The cavity which had existed at the last operation had so contracted that nothing more than a dilatation sufficient to admit a No. 14 sound, English, existed. The pancreas itself had shrunk nearly to its normal size; considerable hardening, however, existed along its head, and was suggestive of an infiltrated neoplasm. The possibility of establishing an intestinal fistula with the pancreas was therefore abandoned, and the opening into this organ stitched up

[1] Senn: Surgery of the Pancreas, 1886.

[1] Medical Record, December 10, 1892.

with deep and wide-reaching sutures. This part of the wound was then firmly packed from the line of suture to the surface with iodoform gauze.

Though it was well known to both Dr. Hartley and myself that patients with biliary fistulæ can discharge externally, without apparent detriment to health, a large amount of bile,[1] in one instance two hundred and thirty grammes for eight years, and also that the closing of the pancreatic opening, even though it healed, would not help the secretion of that organ to get into the intestine, it was considered, under the present serious conditions, it might be of benefit to pour the secretion of the liver into the intestinal tract. This was accomplished rapidly by separating the opening of the gall-bladder from the abdominal wall and inserting into it one of the portions of a Murphy's button, and placing the other portion of the

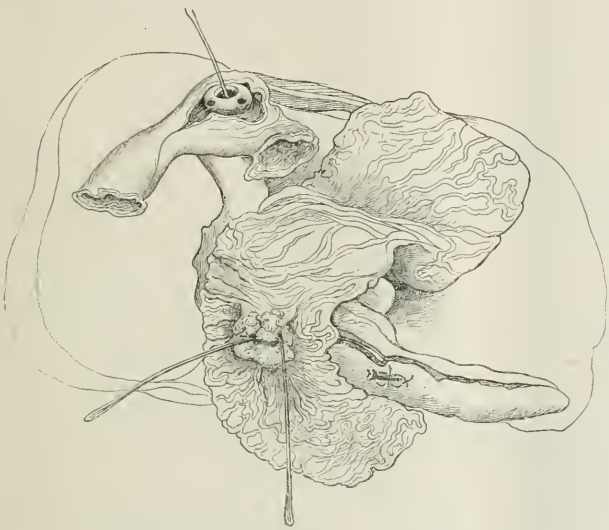

Fig. 2.—Obstructive Carcinoma of Duodenal Papilla. Probes have been carried through the (post mortem) dilated papilla (1) into the slit-opened pancreas and (2) through the common duct and gall-bladder, emerging at the cholecystenteric fistula established by means of Murphy's button.

button into a slit in the upper part of the jejunum, after which the flanges[2] of these buttons were held *in situ* in the intestine by a purse suture introduced prior to the incision and which closed the incisions tightly against the projecting cylinders; pressing the two projecting portions of the button one into the other, a proper approximation was made, and the fistula completed. The actual time in making this part of the operation did not exceed eight or ten minutes. The abdominal wound was then closed, as in the previous operation, save where the strip of gauze and pancreatic suture emerged. The patient's strength, during the first part of the operation, held out fairly well, but at the end of the surgical procedure he was much exhausted and gave but little hopes of long surviving; in fact death ensued within two hours after the completion of the operation.

The specimen obtained at the autopsy revealed a small, soft tumor, 3 ctm. in length, the longest diameter being parallel with the axis of the gut and rising slightly above the level of the intestinal mucous membrane. It presented a general cauliflower appearance (see Fig. 2), and on subsequent microscopical examination was found to be a carcinoma. The duct at this point at first was thought to be impervious, but after manipulation a plug of thickened bile and mucus escaped through the tumor, after which a probe could be passed, with some difficulty, from the cystic and pancreatic ducts into the interior of the intestine. Both the common hepatic, as well as the pancreatic, duct were very much dilated and thinned. The proximal third of the pancreatic duct was remarkably dilated, the head of the pancreas was hard and did not appear to be encroached upon by tumor tissue. The body of the pancreas, and also the tail, appeared to be normal on section. The liver was stained from the coloring matter of the bile, its ducts were dilated, and through all the organ there was an increase in connective tissue. There was one small white nodule found on the under surface of the left lobe, 1 ctm. in diameter. At the autopsy the apposition produced by the use of Murphy's button was found to be in a satisfactory condition.

In connection with the foregoing case I venture to present to the notice of the Society another in which a pancreatic cyst was inferentially due to a calculus in the duct of that organ.

II. Pancreatic Cyst from a Calculus—Impaction Removed by Manipulation—Mrs. H. L——, aged twenty-seven, was referred to me by Dr. Dingman, of Spring Valley, N. Y., February 27, 1888, with a history that up to two years ago she had been in good health when an attack of cramp like pain began in the abdomen, which lasted intermittently for a period of four months and then ceased. Eight months ago these attacks were repeated, coming on in precisely the same way as the first ones. They did not last long, only one of them continued for several hours. Four months ago she noticed the rather sudden appearance of a hard, tense swelling in the upper part of the abdomen. This continued to increase in size for three days, when, during the night, without apparent cause, it suddenly disappeared, and a considerable quantity of fluid was, within the next twenty-four hours, discharged from the bowels. No constitutional symptoms followed, except weakness and loss of strength. Sixteen days ago the tumor reappeared in the same place as the first time, and it slightly increased in size for six days, when it was tapped and a pint of dark, wine-colored fluid was withdrawn. A specimen of this fluid was submitted to an examination by Professor W. Gilman Thompson and pronounced by him after a number of tests to be pancreatic. The tumor has since remained of the same size.

During the past eight months the bowels have been constipated, but the fæces have been of a dark-brown normal color.[1] The patient has not noticed any change in the power of digesting fats. On admission her temperature was 102° F.; pulse, 100; urine free from albumin and sugar. On examination the abdomen was found to be considerably distended, with the swelling more prominent on the left side, and situated well above the umbilicus. The tumor was very globular, tolerably well defined, tense, and presenting an indistinct wave impulse. It was dull on percussion, and no change in the percussion-note was observed when the patient was moving about. An aspirating needle withdrew fluid which had the characteristics on examination by Professor Thompson as follows:

Color of a dark brown-red; on dilution with an equal bulk of water it gives the color of hæmoglobin solution; strongly alkaline; specific gravity, 1.014; somewhat fetid in odor; well-marked viscidity; bile pigment absent; no peptones present; neutral oils were emulsified by it; albumin and egg-albumin were slightly and feebly digested; raw starch unaffected, cooked starch thoroughly converted into glucose; albumin present in slight amounts. Microscopical examination showed numerous leucocytes

[1] Courvoisier, Pathologie und Chirurgie der Gallenwege, 1890, cites instances of total escape of bile through a fistula for periods of two to twelve years, yet, generally speaking, such complete flowing brings speedy death.

[2] Vide Dr. Murphy's paper, loc. cit., Figs. 2, 3, and 4.

[1] Walker, of London, maintained that pancreatic secretion was necessary to produce the usual dark-brown coloration of the fæces, since bile only tinges these of a light brown. The case above narrated goes against the idea.

and large, round cells containing protoplasm and pigment. Few small crystals appeared, apparently phosphates; no red blood-corpuscles. Diagnosis, pancreatic fluid.

The next day, February 20th, she was put under ether, and at the examination before the exploratory incision was made, it was noticed that the abdomen was unusually flaccid, and only a deep obscure mass could be recognized in place of the tumor which had been readily felt the day before, when quite a thorough examination had been made by several surgeons. Nevertheless, a small two-inch incision was made in the median line well up above the umbilicus and two fingers introduced. No fluid tumor could be felt, but in the situation of the pancreas was a mass, apparently as large as the two fists, which extended across the median line, more prominent on the left side than on the right, quite hard in consistency but no irregular nodules of undue hardness were felt in it. The cyst was supposed, from this examination, to be due to either a calculous obstruction of the pancreatic duct, which at times completely closed up the exit of the ordinary secretion, or else to a neoplasm exerting a similar influence. The abdominal wound was closed up, the patient made a prompt recovery, and returned in due time to her home.

From that time to this, five years, she has been under observation, and up to several months since, when last heard from, she has been in good health, without a recurrence of the tumor or attacks of abdominal pain. It seems as if this might therefore be considered a case of calculous obstruction of the pancreatic duct removed accidentally by manipulation.

THE MODERN AND HUMANE TREATMENT OF THE MORPHINE DISEASE.[1]

By J. B. MATTISON, M.D.,

MEDICAL DIRECTOR, BROOKLYN HOME FOR HABITUÉS.

Obersteiner, the eminent Austrian alienist, writing, in 1883, of the morphine disease, declared—"Quite an incredible number of our colleagues have fallen victims to it, and many have only just escaped." History has repeated itself along this line, during the last decade, with startling and sorrowful frequency, and the end is not yet; for it is a well recognized fact—which my own experience fully and increasingly attests—that among our own profession morphinism finds its favorite victims. Granting this, no apology is needed for bringing this trite—to many, it may be—topic before a congress of medical men, some of whom have, it is safe to say, a more or less direct, personal, perchance, painful interest in the question it involves.

For nearly one-third of a century, this disease has had a place on the list of toxic neuroses. During many of these years it was added to largely—almost wholly—by the favorite form of subcutaneous medication; a method facile, yet often fatal—but which, happily, is now, in my opinion, decidedly on the decline. While felicitating ourselves that the progress of this destroyer is less rapid than in days agone, we cannot ignore the fact that it is still with us, and that whatever holds out the promise of undoing the mischief it has done, whatever gives assurance of ending, or even lessening, the ruin it has wrought, must have a claim upon our interest, and make worthy the best effort at our command.

It is now nearing a quarter century since a case of this disease first came to my care. For most of these years my attention has been exclusively devoted to its study and cure, with a result that warrants me in asserting at no time has the treatment been so simple, satisfactory, and successful as now.

The modern and humane treatment of the morphine disease—pre-eminently an American plan—is compassed mainly by three drugs—bromide of sodium, codeine, and trional. These form a combination of unrivalled value, if properly used, in proper cases, and, with certain minor aids, make a method far in advance of any yet presented to accomplish two leading objects—minimum duration of treatment and maximum freedom from pain.

In 1876, the attention of the profession was invited by the writer, to a new application of the well known power of the bromides to subdue reflex nervous irritation, by commending the use of bromide of sodium in this disease, after a plan quite original, which consisted in giving it, in gradually increasing amount, often enough to secure the effect of a continuous dose, for six to ten days, during which time the habitual opiate was to be gradually, but entirely, withdrawn, the object being to secure, by this preliminary sedation, a maximum sedative influence from the bromide at the time of maximum nervous irritation from the opiate-ending.

This, too, was the origin of what is known as the "rapid method," and history will attest the writer's claim to whatever of merit it may have, though, by many, it has been placed mistakenly to the credit of a foreign physician. This plan, a mean between two extremes, avoiding the painful ordeal of abrupt disuse, and the tiresome delay of prolonged decrease, was correct in theory, and in practice proved a success.

The preliminary sedation feature of this method consists in giving the bromide of sodium in initial doses of 30 grains, twice daily, at 10 A.M. and 10 P.M., and increasing this dose 10 grs. each day, *i.e.*, 30, 40, 50, 60, etc., until a maximum of 100 grs. semi-daily, is reached on the eighth day. On the ninth and tenth days, this maximum 100 grain dose is given in the evening only.

This giving of the bromide applies solely to typically eligible cases. With some it is clearly contra-indicated, with others, a minor degree of preliminary sedation will suffice; and with all patients this rule governs: *Each case is a law unto itself, and the length and amount of the bromide giving, and consequent rate of opiate decrease, is determined entirely by individual peculiarity, as shown both before and during treatment.* This must not be forgotten; brains must be mixed with the bromide. This is a point of prime importance, and failure to put it in practice will account for ill success.

Of the value of the bromide thus given, to counteract and control the nervous symptoms usually incident to the morphine ending, there is no question; and it is the absence of this special feature that makes the Erlenmeyer plan, which is complete opiate quitting in two to ten days, inferior to the method we commend.

During this time of bromidal medication, no other treatment is called for, usually, save a tonic regimen, and such regulation of gastric, renal, and alvine functions as each case may seem to demand, in this respect being markedly and favorably in contrast with any method that does not include preliminary sedation, and which makes essential various anodynes, sedatives, stimulants, and hypnotics during the opiate decrease, if the patient's comfort be conserved. For full details of this opiate-quitting régime, see paper by the writer, "The Mattison Method in Morphinism."

Having secured the desired sedation and reached the end of the morphine-taking, whatever reflex symptoms present are met, mainly, by codeine. This is the second special factor in the modern treatment of morphinism. And it is no excess of assertion to declare that it has revolutionized the therapeutics of this disease. With it, the ordeal of quitting a long-used opiate is robbed of its terrors, and it comes nearer to making a "royal road" to freedom for the captive morphinist than anything now at command.

Of this therapeutical triad, codeine is the most important, for it can be used with good in all cases, whereas some will present in which the bromide should not or need not be employed, nor is trional essential.

Codeine may be given pure, or in either of three salts—phosphate, muriate, or sulphate. Pure codeine is not fitted for subdermic use. It dissolves with acid and may be given by mouth. Of the salts, the muriate and phosphate are richest in codeine—eighty and seventy-

[1] Read before the Pan-American Medical Congress, Washington, D. C., September 6, 1893.

six per cent.—and the phosphate is freely soluble. My usual solution is six grains to the drachm. The sulphate dissolves in boiling water, two grains to the drachm. The dose should be one to three grains, by mouth or skin, every two to four hours, according to case or condition, and continued in gradually decreasing dose and increasing intervals till no longer required. The dose by stomach should be double that by skin. As a rule, codeine is not called for till after the entire morphine-quitting. If needed earlier, it should be given.

Cases will present in which the bromide need not, or should not, be used. In these codeine, with, may be, some hypnotic, a few nights, will serve every purpose.

The credit of first commending codeine in morphinism belongs to an American physician—Lindenberger, of California—who, in 1885, claimed for it merit after a method of his own. Later, Schmidt, Fischer, and Rosenthal, abroad, asserted its value, and my own experience, large and enlarging, makes me regard it my most valued aid.

For larger details along this line, vide the writer's paper, "Codeine in the Treatment of the Morphine Disease;" reprint if desired.

The third factor in this modern method is trional. Of hypnotics this is the latest, and in treating narcotic habitués the greatest. There is no doubt of this. I have given it hundreds of times, and say whereof I know. It is better than sulphonal—its nearest rival, and which, till the advent of trional, led the list of hypnotics in this condition—having an effect more certain, pronounced, and prolonged. My usual dose is forty grains for males, and thirty for women, given dry on tongue at 7 P.M. in the evening, after the last morphine-giving. It is largely soluble in hot water, milk, soup, or tea, and thus taken, acts quite promptly. It is not only *the* soporific in these cases, but is markedly sedative, and so serves doubly for good. We use it exclusively during the first six or eight nights, decreasing it gradually to half the initial dose, and then, if needed, resort to chloral, paraldehyde, or cannabis. Some cases do not require it. One of the most striking ever under my care, now making a good recovery, has done notably well without it, codeine phosphate having secured several hours sleep each night. My opinion, steadily growing, of trional in the insomnia of morphine habitués, is that it is the most valuable soporific we now possess. See my paper, "Trional, the New Hypnotic; its use in Narcotic Habitués;" reprint on request.

Such are the main measures in the modern treatment of the morphine disease. Minor symptoms along various lines will, at times, present, to be met, as they can be, and effectively, as they seem to demand. Treatment must needs be varied, as case requires. The patient as well as his disease, must be treated. Details need not detain us. They are at command of any who desire, in the paper first cited: "The Mattison Method in Morphinism."

Regarding humane treatment, a brief statement of fact and this paper is ended. In 1879 Levenstein presented his "Morbid Craving for Morphia," a book valuable along some lines, but harrowing in its gruesome tale of suffering incident to his plan of treatment. Since then this method—abrupt and entire disuse—has found favor with some medical men, who, from ignorance or disregard of distress—either of which is without excuse—have been led to commend it. These men, misguided and mistaken, may mean well, but they fail to appreciate the sorrow their counsel entails, and it is safe to say, were they forced to run the gauntlet of such suffering, were they bound to the rack of such torture, there would be a rapid and radical change of opinion.

Levenstein's grim tale—cold and terse as a hardware catalogue—of the tortures through which the patient passes—the days and nights of writhing, the sleeplessness, the restlessness, the thirst, the endless vomiting and purgings; his vain pleadings for liberty, for morphia, for anything which will relieve the intolerable anguish—are fairly burning with their burden of tragedy!

In 1883, an American physician, T. L. Papin, said, "Suppose your patient is habituated to morphia, how will you cure him? Let him quit short, absolutely, and entirely. If he have the will-power, trust him; if he cheats, lock him up; put a Hercules over him as a nurse. All substitutes are simply a prolongation of the agony he must go through. The patient who quits morphia suffers from insomnia, diarrhœa, nausea, vomiting, achings, and debility to such a degree that it is a marvel how he lives. All this suffering will last five to ten days. No medicine will do any good; the stomach rejects everything, even a mouthful of cold water. At last, after several centuries of torture, little by little, and without medicine or substitutes, nature accomplishes the cure. This terrible treatment, I am sure, is not only the best, but the only safe one to cure and secure the patient against a relapse."

Well may one stand amazed and aghast at the "cruelty" of such "ignorance," and well may Bartholow declare, "Having had one experience of this kind, I shall not be induced to repeat it; if for no other, for strictly humanitarian reasons, since the mental and physical sufferings are truly horrible."

In 1888, a teacher in one of our leading medical schools—J. C. Wilson, University of Pennsylvania—in a clinical lecture, commended this treatment: "The patient is put to bed, and the physician administers the drug hypodermatically. During the first twenty-four hours the dose should be that he is in the habit of taking. The next day, the dose should be diminished one-half. The following day it should again be diminished one-half, and by the fourth day the dose may be entirely stopped. As soon as the physical effects of the morphia which has been taken, pass off, there is relaxation of the vaso motor system of the intestinal tract, with a pouring out of fluid into the intestines and stomach, with copious vomiting and free diarrhœa, often colliquative. There is intense craving for the drug. There is marked nausea and inability to take food. There is complete sleeplessness, and, sooner or later, delirium appears, and this is often attended with tremor. Finally, the delirium may become intense and active, and during this period there is danger of sudden heart failure and collapse, which in some cases have proved fatal.

"With reference to the necessity for this sort of treatment, it may be said that it is desirable to undertake it in every instance where you can prevail upon the patient and his friends to submit to it. It is not without much suffering and some danger. There are cases in which, from heart failure, the danger to life is so great, you must abandon the attempt."

Sorry, indeed, the lot of a hapless morphinist under the care of any physician so lacking in skill or feeling as such counsel implies; and, verily, a teacher like that has mistaken his calling along this line, and should limit himself to a field in which larger knowledge and broader experience give his counsel greater weight.

In 1893 another American doctor, E. P. Hurd, in a paper on "The Erlenmeyer Treatment," wrote: "The method contemplates and seriously attempts the entire withdrawal of morphine in about a week, the daily dose being first cut down one-fifth, then two fifths, then three-fifths, then four-fifths, and so on till none is given. *During the period of withdrawal* (italics mine) the place of the morphine is supplied by various stimulants, narcotics, and hypnotics. It may be necessary during the first week to give large quantities of whiskey, almost to intoxication; chloral and sulphonal in large doses, quinine and strychnine, will also be needed to meet indications. After the last dose of morphine has been given the patient will be in a condition of great depression, and powerful stimulation will be required for a few days; sometimes diarrhœa or collapse will indicate the necessity of a temporary resort to morphine or to deodorized laudanum. Then, when the patient is sufficiently weaned from morphine, the task is begun of weaning him from the drugs and from the alcohol by a tapering off plan which will require about three weeks. Naturally, it is a month of

anxiety to the physician, and of trial and suffering to the patient."

What a travesty on rational therapeutics! If such be the "Erlenmeyer treatment," the less of it the better. In justice to this eminent German physician, whom I personally know, I am bound to say I do not accept it as his method.

Modern medicine has done much for humane relief of the hapless morphinist, but that ignorance of this advance still obtains, the following extract from a letter recently sent me by the writer last cited—Hurd—will well attest. He wrote: "If you, or any other man, or an angel from heaven, were to tell me that the morphia 'habit' could be cured without great physical suffering, I would reply that this is intrinsically and scientifically 'improbable!'" What presumption! this in the face of his further statement: "I am free to confess myself only a novice and learner, and have not yet passed beyond the state of tentative experimentation for that of positive and scientific certainty." Let me assure this gentleman, and all other like sceptics, that the time of "tentative experimentation" in the therapeutics of the morphine disease, has *gone*; the day of "positive and scientific certainty" has *come*.

The Levenstein method is crude in theory and cruel in practice. It is brutal—utterly unworthy a healing art—and needs only to be described to be denounced. It incurs the risk of a fatal ending, has killed more than the world will ever know, and brought many perilously near to death. It has no claim to merit, either in abridging treatment or preventing relapse. Jennings truly says: "Dreadful as are the tortures inflicted, they do not, as a matter of fact, afford any safeguard against relapse." Most of Levenstein's patients had return of the disease, "notwithstanding the unwarrantable tortures to which they were subjected."

No valid excuse can be offered for its practice, save in rare cases, where conditions are peculiar and quite beyond control; and any physician so ignorant or inhumane as to counsel and compel it, except under such conditions, deserves to be made defendant in a suit for malpractice. The Erlenmeyer method, while less distressing and disastrous than the Levenstein, entails much suffering that can be avoided. It has no special merit as effecting rapid or radical cure, and does not, in any way, well compare with the humane method we commend.

Quite apart from the merit of this humane method on the score of humanity, it has another bearing which is far-reaching and important. There can be no question that the dread of such suffering as attends the largely held idea of escape from the thraldom of morphia, is a decided bar to many an effort in this regard. Many think escape only possible through prolonged distress, and, despite a consummation devoutly wished, prefer to bear the ills they have. A notable case in proof is recalled. Fifteen years ago, a naval surgeon, three years a hypodermic morphia-taker, first consulted me. Six years later he came to my care, and avowed the reason of his delay was the reading of Levenstein's book, and fear of such suffering as that treatment entailed. This gentleman made a surprisingly good recovery, was dismissed on the thirty-second day, and has remained—nine years—well.

When the practice of this humane method more largely obtains, we shall note a steady increase in the number of ex-poppy habitués.

Mr. Chairman, this paper is a plea for merciful measures, to release from a galling bondage—made such by force of conditions beyond control—many who are deserving of deep commiseration. These measures are surely at command, and the medical man who does not, or will not, so acquaint himself, had best consign such cases to other care. Few advances in modern therapeutics have been more marked than the one to which we refer: and the writer is both glad and grateful that it has been his privilege to proffer humane help to many bearing the grievous burden of this phase of human ill.

Prospect Place, near Prospect Park.

NOTE UPON THE OCCURRENCE OF INDICAN IN THE URINE OF INSANE PATIENTS.

By E. D. BONDURANT, M.D.,

Assistant Superintendent of the Alabama Insane Hospital at Tuskaloosa.

Indican, $C_{52}H_{62}N_2O_{34}$, classified as one of the normal coloring substances, or, more correctly, color-producing substances of the urine, has come of late years to possess a certain pathological interest, and even some, although as yet it must be acknowledged questionable, value in the diagnosis of morbid bodily states. It is supposed to exist in minute quantity in the urine of all persons after the age of infancy, but in so small proportion—five to ten milligrammes per 1,000 c.c.—as to give no reaction with the tests ordinarily employed. This quantity, however, varies widely in different individuals and at different times; is largely dependent upon the character of the food, being increased by a meat diet (Von Jacksch), and is enormously increased in certain pathological states. It has been noted in large amount in the urine of patients suffering from abdominal tumors, especially carcinoma of the liver, tuberculosis, typhoid fever, Addison's disease, cirrhosis of the liver, peritonitis, inanition, and, in especially large quantity, in many forms of intestinal disorder, complete obstruction standing at the head. In the lower animals its excretion has been found to be wonderfully increased after experimental ligature of the small intestine.

The method of its physiological production, and the rationale of its increase in the various forms of disease above enumerated, is, according to the researches of Baumann and others, about as follows: Indican is a derivative of indol, and is formed in the blood by a process of oxidation whenever indol makes its way into the circulating fluids. Indol is a constant product of the action upon albuminous matters of the bacteria of putrefaction, and is also found during late stages of pancreatic digestion. Any interference with or delay in the process of intestinal digestion, and, in particular, any obstruction to the ready passage of the intestinal contents, by favoring fermentative and putrefactive changes, increases the production of indol, and furnishes to the blood the mother-substance for the elaboration of indican. This same result may, in a lesser degree, be brought about by putrefactive changes in other parts of the body, as in a case of a decomposing pleural exudate, reported by Von Jacksch, and in purulent peritonitis. In general terms, and with exceptions and limitations, it is in those diseases accompanied by disordered intestinal digestion that abnormal increase in amount of indican excreted by the kidneys is found.

In the wards of our State Insane Hospital, in the course of a somewhat extended clinical study of the nephritic complications of insanity, involving among other things the frequently repeated examination of the urine of a large number of insane patients, some attention in passing has been given to the subject of *indicanuria*, with a view to discovering if the presence in the urine of an increased amount of indican could be made of any practical value in the diagnosis of disease among the insane.

The results have in the main been disappointing. Indican in amount greater than normal has been found in a variety of cases, representing a large number of mental and bodily disorders, but such increase is seemingly not peculiar to nor characteristic of any single morbid state nor group of symptoms. A few patients in average health have exhibited a notable increase, while some in the last stages of bodily disease returned a negative result, though a considerably larger proportion of cases showing distinct indicanuria has been found among the weak and ailing than among the strong and robust.

In reviewing the mental symptoms of the cases examined, however, a feature of some interest is discovered in the noticeably greater frequency of indicanuria among the acutely insane, the proportion being more than twice that shown by the patients suffering from chronic forms

of mental aberration. The truth of this statement is made at once apparent by the figures of the table below.[1]

Forms of Insanity.

	Total number examined.	Showing increase in indican.
Chronic mania, melancholia, and dementia	193	13
Chronic insanity with epilepsy	41	4
Paranoia and states of defective development	7	1
Acute mania, melancholia, and dementia	160	34
Acute delirium	5	2
General paresis	5	1

Less than eight per cent. of the cases of chronic insanity show an abnormal amount of indican; more than twenty per cent. of the acute cases yield a ready reaction to the tests. The most reasonable explanation of this difference is to be sought, not in any peculiar influence exerted upon the vital processes by the varying mental states of the patients, but in the widely differing states of physical health of the two classes. The chronic cases, having survived the stress of acute mental disorder, measurably recovered from such bodily ailment as may have existed, and readjusted to life upon a lower plane, are, as a class, in comparatively good health, all animal functions being properly performed. Many of them attain a good old age. The more active forms of intellectual disorder, on the contrary, are most usually attended by a derangement of the vital mechanism, often of a serious nature; tissue-waste is active, and the digestive and general restorative processes are imperfectly carried on.

Such grave disorder of the digestive and assimilative apparatus as is so frequently seen in the states of acute delirium, typho-mania, and other active forms of insanity is doubtless sufficient to induce over-activity in the fermentative changes in the contents of the small intestine, with consequent increase in formation of indol, and its derivative, indican; and it is precisely in those cases of insanity accompanied by intestinal disorder that increase in quantity of indican in the urine has been most frequently noted. As further indicating the physical disorder as the essential agent in causation of indicanuria, it is noteworthy that as the bodily disorder subsides, the patients progressing to recovery or to chronic mental disorder, the indican usually falls to normal amount. Be it observed, however, that not all cases of acute insanity with intestinal complications exhibit indicanuria as a symptom; and that, as above mentioned, a small proportion of persons in comparative health do show an unusually large percentage of urine indican.

Of other forms of disease in which clinicians have reported the existence of indicanuria, examples of several have come under notice here.

Examination in nineteen patients suffering from tuberculosis of lungs and other organs resulted in the detection of indican at each of two or more analyses in seven of the cases; in two others indican was found at a single examination, but not subsequently. Five of the seven had tubercular disease of small intestine and mesenteric glands, as shown by autopsy, with bowel disorders during life. The presence of large amounts of indican in the urine of tubercular patients has been several times referred to by writers. Hochsinger, in Vienna, in 1890, published a paper in which he claimed the presence of indican in the urine of children less than six years of age to be absolutely diagnostic of tuberculosis in some form. Kahane shortly thereafter corroborated this statement in part; but observations by more recent writers (Steffen, Voute) have not seemed so conclusive. Among adults the symptom is of little value, although the excretion of large amounts of indican is more frequent in tubercular cases than in persons in fair health.

In three cases of partial obstruction of the bowel with peritonitis, indican was found present in large quantity. Two of the cases terminated in death. In the third case, which ran a more favorable course, the indican was found at every examination made during the height of the attack, but disappeared as convalescence was established.

We have had two cases of carcinoma of the breast, each of which showed indicanuria. In the first case the mamma was amputated; the growth, recurring, was removed a second time, and glands in axilla were extirpated; growth recurred in glands of the neck and in the tissue of the lung, patient finally dying by suicide some five years from time of first appearance of the tumor. Indican was found at every examination made during this time. In the second case removal of the tumor and improvement in general physical state was followed by subsidence of the indicanuria. The tumor has not recurred, and indican is not now present in the urine.

Many of the cases of indicanuria are complicated by the presence of albumin and casts in the urine, and among them are not a few cases of severe renal lesion. In the more severe forms of nephritic trouble the proportion of cases of indicanuria is especially large. This is equally true of the non-insane patients who have been examined. Of fifty-eight such cases, six showed increase in indican, and of these the two giving the largest increase were cases of well-marked and eventually fatal Bright's disease.

In the mild transient diarrhœas prevalent during the summer months the proportion of cases of indicanuria is not especially great.

The table appended will show the forms of disease represented among the fifty five cases of indicanuria reported.

Tuberculosis	7	Morphinism	1
Carcinoma mammæ	2	Septicæmia	1
Intestinal obstruction	3	Ulcer of leg with debility	1
Diarrhœa (uncomplicated)	3	Heart lesion	2
Acute nephritis	5	No bodily ailment, but health not robust, albumin and casts in urine	10
Chronic nephritis	4	In apparent good health	7
Puerperal state	3		
Chronic bronchitis	1	Total	55
Chronic malarial poisoning	1		
Epilepsy	4		

It may be said, in brief recapitulation, that an increase in the proportion of indican present in the urine usually indicates disordered intestinal digestion, and such intestinal disturbance constitutes the essential feature in the large number of different maladies, including acute mental disease, in which indicanuria has been reported. In certain cases its discovery may throw some light upon obscure symptoms, which fact, together with the ease with which the tests may be applied, would justify a test for indican at each and every urinalysis; although in the present state of our knowledge of the subject, any very positive value cannot be assigned to its presence in the urine in abnormal quantity.

[1] Cases giving a reaction for indican at one examination, but in which subsequent analysis proved negative, are not included; so that it may be assumed that the indicanuria persisted during a longer or shorter time in each of the fifty-five cases reported. The tests employed are Weber's, Jaffe's, and Heller's, detailed accounts of which may be found in any work on urinalysis.

Hartford Medical Society.—The Medical Society of the City of Hartford, organized in 1846, is to receive a fund for the erection of a building to be devoted to its purposes and to those of the medical profession of that city. It will be in memory of the late Dr. Ebenezer Kingsbury Hunt, formerly president of the Connecticut State Medical Society, in compliance with the terms of a bequest of the late Mrs. Mary C. Hunt, of Hartford, widow of the late Dr. Hunt. The medical school at Yale University will also fall heir to the sum of $25,000 under the will of Mrs. Hunt.

The Symptoms of Coryza Accurately Stated.—A four-year old caught a severe cold while his mother was out of the city, and on her return rushed up to her, and throwing his arms around her, cried, "Oh, mamma, both of my eyes is rainin' and one of my noses won't go."

ASTASIA-ABASIA.[1]

By W. C. WEBER, A.B., M.D.,
CLEVELAND, O.

Mr. President and Members of the Society: The case which I am about to describe is one of rather rare occurrence, and possesses more than a passing interest. This patient was under daily observation by Drs. F. C. Taylor and R. Pollock, house physicians of the City Hospital, and myself.

History of the Case.—Mr. S——, aged twenty five, Russian, in the United States six months. Heredity good, no acquired or venereal dyscrasia. Laborer, and always in excellent health until present illness. He insists that his personal habits have always been correct, notwithstanding the fact that he has consumed sixteen ounces of alcohol daily for some time before he became a resident of our country, and since which time he has experienced no inconveniences in his efforts to substitute our own national beverages for those of the land of his nativity.

A few days prior to his admission to the hospital, patient experienced a slight dizzy sensation, became entangled in coils of red-hot wire, in an iron-works in which he was employed, fell to the ground and sustained several burns from the second to the fourth class on the forearm and around one lower extremity, midway between the knee and ankle. For the burns he received the usual treatment, and as far as these local injuries were concerned, made a rapid recovery.

When it was decided to permit patient to leave his bed, he was greatly surprised to find that he was unable to stand. In order to ascertain whether the cause of this was debility or a loss of the power to guide or control the movements, his body was now supported by two men, but he could no more walk than he could stand alone before.

While in the dorsal decubitus or when sitting, he possessed the ability to describe any normal motion or to exhibit a considerable degree of muscular strength, though he was not of the muscular type.

Careful examination revealed the following: A complete degree of analgesia extending from the toes to the body, about one or two inches above the pubis. At any point in the designated area a pin or any sharp-pointed instrument could be thrust without eliciting the slightest pain. The tactile and thermal senses were normal. The patellar tendon reflex was completely abolished. Digestion was good, and the circulation normal. The lungs and other internal viscera were also normal.

In the recumbent or sitting postures the various muscular movements are executed with perfect ease; but no sooner is the erect posture gained than all the co-ordinative power is lost. Certain groups of muscles are in spastic contraction, while others are in a state of relaxation, during the attempt to stand or walk.

Astasia abasia is the name given to the disease, which has been defined as a functional neurosis of a variable symptomatology in which the inability to stand or walk is constant.

Charcot and Weir Mitchell were among the first to call attention to this group of symptoms, about eight or ten years ago. But it was not until 1888, that Blocq described the disease very thoroughly, reporting a dozen cases, giving it its name and the following definition: "A morbid state in which the impossibility of standing erect and walking normally is in contrast with the integrity of sensation, of muscular strength, and of the co-ordination of the other movements of the lower extremities." Recently Dr. Knapp has gone into the subject very exhaustively, detailing fifty cases—all that are on record to date.

Anæsthesia, hyperæsthesia, visual disturbances, an exaggeration or diminution in the heat or muscle senses, usually with increased reflexes, are symptoms which are present in a variable proportion in nearly all cases. The greater number, perhaps, of observers of this disease incline to the view that it is related to hysteria and allied neuroses, while others admit the presence of an organic lesion in the spinal cord in certain cases. In all these cases the tendon reflex was diminished in only three or four, and the sense of pain in none.

The case which I report differs from those whose description has been noted in the following points: In this patient there was a complete absence of the patellar tendon reflex. There was complete analgesia. There was no history of any previous nervous disease, nor was there anything in his general appearance indicative of a hysterical neurosis. He was a hard laborer, accustomed to coarse food and an out-door life. In the cases hitherto reported the great majority were of the nervous temperament, and the remainder of sedentary habits.

The treatment consisted of alcoholics in no form, strychnia, grain $\frac{1}{30}$, every four hours, a nutritious and easily digested diet, and absolute rest. Patient made a good recovery in about three months.

The absence of evidence of any neuroses, the exemption of any previous disease, and his addiction to the use (more properly abuse) of a beverage so rich in fusel oil, are some of the reasons for regarding the pathology of this case as of an organic rather than a functional character.

Some of the diseases which naturally suggest themselves in connection with the subject in hand, and from which it must be differentiated, are multiple neuritis, tabes dorsalis, disseminated sclerosis, myelitis, paraplegia, etc.

It is not intended to discuss here the various diseases which bear a resemblance to our case, but simply to point out such differences as shall enable us to see the non-identity of these diseases.

The manifestations of the neuritis produced by alcohol are varied and peculiar. For sake of simplicity they can all be described under two varieties, though the clinical phases cannot always be differentiated. In the one, there are motor disturbances and atrophies, and in the other the disorders are sensory. In the former, the gait becomes ataxic, and closely resembles that of a tabetic, with the distinction that in the latter there is no loss of muscular strength, while in the former there is a comparatively early diminution in strength in consequence of muscular atrophy, which by preference affects the extensors in the beginning. In this variety there may or may not be present transient, violent drawing pains, principally in the lower extremities.

The patellar reflex is in many instances lost early, which may lead to an erroneous diagnosis of tabes dorsalis; especially may this happen if the alcoholic effects have extended to some of the ocular nerves. The absence of the Argyll-Robertson pupil, Romberg's sign, and the bladder symptoms in tabes, renders a differential diagnosis comparatively easy in the majority of cases.

The second form of alcoholic neuritis may exhibit no motor disturbances. Patient may complain only of pain along the course of the nerve, which may be either dull or lancinating in character, resembling the pain of locomotor ataxia. There may be anæsthesia, hyperæsthesia, formication, or numbness, all of which as a rule are confined to the lower extremities.

In acute myelitis there is pyrexia, well-marked trophic changes, a zone of anæsthesia surrounded by one of hyperæsthesia in the early stage. The muscles rapidly waste and the pelvic viscera are often involved

It is only necessary to mention Thompson's disease, spastic paraplegia, and paralysis agitans, etc., to make it patent that we haven't these to deal with, though each of them may have some symptoms in common with the case here reported.

The most interesting feature about the condition which bears the title of this paper is its pathology, concerning which so little is known. Assuming that we have to do with an organic disease, where is the lesion situated?

[1] Read at Cuyahoga County, Ohio, Medical Society, October, 1893.

Doubtless it will be agreed that its location is somewhere in the spinal cord, and probably in the lower dorsal or lumbar segment. If destruction of the posterior nerve-roots results in anæsthesia of the senses of pain, touch, and temperature, it is obvious then that the lesion is not there. The sense of touch being unaffected, it is safe to exclude the posterior columns from the diseased process also. It might seem that the evidence, therefore, pointed to the motor tracts as the part involved, including perhaps the multipolar cells in the anterior horns, thus furnishing an explanation of the absence of the deep reflexes. Of this we are, however, not so sure. The exact location of the various centres of pain, heat, etc., has not yet been definitely determined, but is thought to lie near or within the motor area—probably occupying that portion of the parietal lobe which is not directly concerned in its motor function.

The tactile and thermal impressions, but not the sense of pain, can be conveyed through a cord whose gray matter is impaired or even destroyed, provided the other structures are intact.

It has also been demonstrated in autopsies that in those cases in which existed an inability to appreciate differences in temperature and touch, and in which the sensation of pain was unimpaired, there were either lesions of the posterior columns or other interference with the conductivity of sensory impulses, but there was found in no such instance any destruction of the gray substance.

It is impossible, in the present state of knowledge pertaining to this subject, to determine in all instances, with any degree of accuracy, the exact pathology of muscular inco-ordination. There is not a great unanimity of opinion among writers as to the *modus operandi* of muscular inco-ordination, even in diseases whose pathology in other respects is well understood.

Lyden says ataxia is to be accounted for in a disturbance of sensibility. Some contend that it is a disturbance of the reflex activity in the cord; while Friedrich and others think it a disturbance of co-ordinating fibres. That the topography of lesions of the spinal cord is not yet the exact science we could wish it to be, is apparent, though the acquisition in this line has been considerable in recent years.

The question might be raised if the burns in this man were not the cause of the abasia and astasia instead of the amylic alcohol. This is not probable; for it would be difficult to understand in what manner the temperature and tactile sensibilities could escape unaffected if the abolition of the sense of pain is produced by peripheral paralysis due to the local traumatism.

It will be remembered that a lesion of the cord at any point below the fifth lumbar segment may produce anæsthesia only on the posterior aspect of the lower extremities; and when the lesion extends as high as the third lumbar segment, in addition to the above, the sides of the limbs also become involved; when the lesion is between the third and first lumbar segments, the anæsthesia extends to all parts of the extremities, and reaches an elevation corresponding to the area of distribution of the ilio inguinal nerve.

Now, by referring to the symptoms in this case, it will be observed that the analgesia invaded the highest point supplied by this nerve. As this nerve takes its origin from the first lumbar nerve, it becomes highly probable that the superior limit of the lesion was at a point on a level with the latter.

While it was more the purpose of this paper to report a case than to locate or assign definite pathological lesion to one or more of the various structures of the cord, it seems to me that the following conclusions are in keeping with the findings of our case:

1. The lesion was not unilateral.

2. The posterior columns (Goll and Burdach) were not included in the diseased process.

3. The probability is that the morbid process extended to the central gray matter of the cord, for this only can explain, it seems, the absence of the pain sense in the absence of any other sensory impairment.

4. That there might have been a disturbance of the large cells of the anterior horns which connect the motor fibres from the brain with those of the anterior roots of the spinal nerves, which did not, however, result in marked trophic changes.

5. That the motor tracts probably escaped; for if the destructive process included the direct or crossed pyramidal tracts, it is easily to be seen that the motor impulses would be inhibited.

Position of the body would have little or nothing to do in executing any movement; and therefore, inasmuch as any normal motion, as well as force, was within the power of this patient when in the recumbent posture, lesion of this portion of the cord can be also excluded. This, then, leaves the gray matter in the region before indicated as the only probable seat of the pathological changes.

405 Prospect Street.

THE TREATMENT OF PHTHISIS.[1]

By E. P. HERSHEY, C.E., M.D.,
DENVER, COL.

No time could better present an opportunity for the iconoclast to assert his power than at the close of a century. By numerous interesting articles that have lately appeared in medical literature it seems that the good work of destroying the false images worshipped by many of our profession has commenced early. It is to be hoped that those who take part in this will not be considered cynics, but rather that they shall be aided in their efforts to destroy all that has been useless.

In no disease have we so artfully exposed our ignorance as in that enemy to human comfort—consumption. We have learned its pathology, but each step in its discovery has led to many new treatments. That there are many cases of phthisis that have cured spontaneously has been proven without a doubt. That we have not yet cured a case by direct medication to the diseased organ is also beyond a doubt. There are periods in the history of every consumptive in which, with absolutely no treatment, temporary improvement occurs. Indeed, at certain times it seems as though the patient is on the border-land of recovery, and the same has occurred in spite of all medication. The physician eager to convince the medical world of his skill publishes such cases, and in his enthusiasm forgets many in which the same treatment has failed. Years go by after these various methods have been tested, and as faithfully laid aside, when here and there we meet with many with whom they still find favor.

It would be safe to venture the statement that no matter how absurd the method taken for the cure of consumption it will find its advocates. When these poor suffering mortals anxiously watch for some genius medicus to rescue them from their hopeless condition, ever eager to grasp at the first offer of help, should we wonder at it if, when some mysterious apparatus is presented to them, their whole being becomes animated with hope, and that a new life should take possession of them? When instead of the depressed condition of despair renewed vigor enters their whole system they naturally show immediate signs of improvement. The same effect can be obtained by means of another apparatus diametrically opposite to it. The inhalation of rarefied air has its advocates as well as the condensed air. Pure oxygen goes hand in hand with diluted oxygen, and even the impure atmosphere of the gasworks, as far as the claims of their curative powers go.

Note the periods during the last decade in which certain treatments became fashionable in the cure of consumption. First, compressed air inhalations. Then,

[1] Read before the Denver and Arapahoe Medical Society, October 24, 1893.

with the idea of cooking the mischievous little bacilli, the patient was forced to inhale air at a suitable temperature for that purpose. We all remember the reports of the success obtained by these methods of warfare. Scarcely had their fame died out before the medical world was startled by the reversing of this method by reaching the lungs *via* the rectum — the injections of sulphuretted hydrogen. Physicians were clamoring for the necessary apparatus with which to assail their patients. Shortly after, when that body of sage men congregated to form the World's Medical Congress, many were armed with statistics to prove the efficacy of the treatment, when the assemblage was thrown into consternation by one bright light who suggested that he had discovered an easy method of administering the dose—advising patients to partake plentifully of Boston baked beans. Thus died the supposed great boon to the suffering world.

Everything was quiet for a while, except here and there in the distant backwoods a few flashes would be seen among those who had just learned of the discovery, and with all the faith in the world were trying it, when suddenly there was a leakage in the walls that bound up in secrecy the experiments of one of the most noted investigators in the medical profession—Koch. Soon that breach became a widening gap, and the world became flooded with the greatest discovery of the nineteenth century—a sure cure for consumption. Scarcely had the eminent professor time to ascertain whether the compound killed or cured, before thousands of our brethren had found it infallible, and to day, who among us handling this article of warfare, will claim the greatest number among the slain? But we are too much in haste in calling for statistics as we still have a few that are trying it.

These sure cures must come faster. Hence back in the Buckeye State there suddenly appears a hero. At last the enemy is at our feet. We are daily confronted with numerous testimonials as to the success of a certain treatment. Every city has an emissary of this great king in the person of a duly authorized practitioner. The name of the discoverer is on the tongue of every consumptive. Has it been a success? Yes! in a way. We understand that some poor unfortunate, unable to legitimately gain a livelihood in his town or village has become the recipient of thirty-three and one-third per cent. of the receipts, or five dollars a month for each victim.

Except for cases similar to this last we believe that most of the methods in years gone by have originated in the minds of earnest philanthropic members of our profession; it is not therefore the object of this paper to condemn the originators of the many treatments that have been presented to us in the past, as it is to show how apt we are, in our desire to lessen our humiliation in the eyes of our patients, to accept anything that comes along.

Apart from these mechanical contrivances, what have we in the line of medicaments that have been promised as beneficial in this disease? Alas! their name is legion. For night sweats, atropine, agaricine, camphoric acid, and quinine. For every patient who will give the credit of curing their night-sweats to the physician, who may have used any one of these drugs, there can be brought forward a dozen who will laud the never-failing remedy of the bucket of water under the bed in which the patient sleeps, and a score or more who claim that the night-sweats left them without any treatment.

And the fevers. How they come and go with or without medication, unless it be those cases in the latest stage of the disease, where the fever seems permanent, until after a time we see our patient daily sinking beyond all reach of experimental therapeutics.

What healthy man could withstand the medication to which we submit our consumptives? Our hygienic laws teach us to avoid impure atmosphere. Scientists are striving to invent an apparatus by which the immense volumes of smoke can be consumed that they may not pollute the air of our cities where thousands are congregated in small spaces, and the cry is "give them fresh air," and yet, with an intelligent look upon his face, the physician advises his patient to inhale the very oil of smoke—creosote. Let us extend to our fellow practitioners an invitation to partake of the following health restorers (?). We shall select only a vigorous, hearty man, one who has a healthy stomach, good circulation, and whose lungs are in a normal condition. Let him take what had been the treatment of a patient who recently came under my care, his physician having left town for a few weeks.

Diagnosis.—Dulness throughout the upper lobe of the left lung, slight dulness in the apex of the right. Dry and moist râles at the apex of the right. Bronchophony throughout the upper portion of the left; moist râles at the base of same. Signs of small cavity in left lung. Evening temperature, 101.5° F.; morning, subnormal. Night sweats.

Let our healthy physician commence now on what this patient was taking. Every opportunity he may have left him shut out the pure air by means of a fine wire screen that holds within its concave surface a sponge saturated with creosote. Mark you, the more he shuts out the pure air the better. Then, in order that he may have missed the chances of getting enough of the organic compound into his system, *via* the air-passages, have him take at least three or four times a day some of the same creosote into the stomach, mixed up with pure whiskey, steadily increase the dose to tolerance! (Tolerance of the stomach we presume.) Now let him take five grains of quinine every five hours, and just about 4 P.M. let him take ten grains of antipyrine, acetanilide, or phenacetine. Then just before he is to sink into nature's pure, calm, restorative sleep, let him take a nightcap of opium or belladonna, and if that kind hearted victim of scientific research does not go into consumption at an early date, it will be because either there is nothing in the laws of hygiene or else his system has so revolted against the inhuman treatment that he is compelled from sheer exhaustion to discontinue his test.

We have gone far enough with our experiment, though we may be anxious to try, for our advancement, a few hypodermatic injections of certain dilutions of the quintessence of putrefaction known as "tuberculin," thus further impoverishing his blood; or, being anxious to ascertain just how long the patient's circulation can stand it, we might suggest what is now highly praised, a mixture of guiacol and iodoform in sterilized olive-oil.

It is a serious matter, and seemingly an important one, for anyone to doubt reports of cures as reliable as they have come to us concerning the benefits derived from certain forms of treatment. But how is it, with so many benefited or cured by the various methods, that we are not using them now? We meet only with an occasional remnant of an old fad, forced upon a patient by one who either has not yet witnessed the ruins, or else who holds on to it as the most plausible method to present to the innocent.

It seems almost incredible that in the face of our knowledge of the pathological changes that occur in the lung-tissue in tuberculosis, that so many intelligent physicians should attempt to conquer the disease by so many methods opposed to common-sense. A fleeting thought of a great man becomes a theory, and in the minds of thousands this theory is forced into a fact. But the poor suffering patient, how about him? Instead of pure air he gets stifled with various forms of polluted atmosphere. In place of his stomach receiving good nutritious food, drugs of all descriptions are forced into it. Instead of allowing the already weakened circulation to aid in restoration, it is contaminated with foreign substances, which throw an extra burden upon the organs of elimination.

A disease essentially the result of ill development from malnutrition, a process of slow decay due to an absence of vitality, cannot be whipped into renewed activity. The death of any portion of the body cannot be restored

to life by internal medication. Decay suggests the surgeon's knife. But the surgeon must admit his inability to apply his art to so delicate and active a structure as the lung. Of all the medication that has been suggested within recent years for tuberculosis, none has as yet proven itself worthy of further trial, and there remains yet a treatment that will surpass that laid down by Alonzo Clark, who, after sixty years' experience, advised, in a lecture delivered in 1882, the following:

"Consumption may be cured in its early stages. Horseback exercise, twenty-five miles daily. One to one and a half quart of milk with a half pint of cream daily. Rare beef. Friction to the surface of the body night and morning. Peaches. In case of poor appetite, a teaspoonful of tincture gentian comp. in a good sherry wine three times a day, and in case of severe cough, spray the throat with glycerine and water, a grain of opium to the ounce." Surely no method could be more simple than this.

Have not the recent so-called advancements made in the treatment of consumption greatly increased the rate of mortality? It would be an injustice to assert that physicians wantonly retain their patients until such time as climate will prove of no benefit to them. Sustained by what should be reliable statistics, they feel warranted in subjecting their patients to the advocated treatment only to find out that time has been lost, and so the patient is held back so long that climate proves of no avail.

We have all had more or less experience with consumption, and we find unreservedly that all the cases we provide with death certificates give you a line of treatment they underwent for months before coming to Colorado; on the other hand, how many patients we have had, now in the full vigor of health, who were either well advised to go, or of their own free will came, to this country in the first stage of the affection. Even some of the more advanced cases improve and get well if the good effects of pure rarefied air are not counterbalanced by too much drugging.

The same desire to medicate so prevalent in the lower altitudes infests us. The patient escapes his physician at home only to be waylaid by one here, or he may soon be led with the belief that though his physician at home was wise enough to know the uselessness of medicine, he should have his stomach filled with various drugs, thus depriving him of what might have been a benefit—the unencumbered effects of an exhilarating climate.

The accompanying table will show the comparative results of delay and promptness in change of climate, a few cases still living, but showing signs of rapid failure being classed as fatal; also entering those who show such signs of improvement that, from our experience in such cases, are either sure to recover or else live many years without inconvenience from their affection, as cured. The cases originating in Colorado give histories of feeble vitality; in one, the mother dying of consumption soon after the birth of the child, another losing both parents from the same disease, the mode of life in both cases being such as to provoke lung trouble. The word treatment is used strictly in the sense of direct attention to the lungs by any of the recent methods.

Cases.	Originating in Colorado.	Treated 2 to 5 years before coming to Colorado.	Treated 1 to 2 years before coming to Colorado.	Treated 3 months to 1 year before coming to Colorado.	No treatment before coming to Colorado.
Number, 328 ...	8	92	90	41	97
Fatal....	5	62	32	8	5
On the road to recovery.....	3	26	36	19	25
Recovery	..	4	22	14	67
Per cent. of fatalities.	62½	66⅔	35⅝	19½	5⅛

Except in very rare instances phthisis florida, or the so-called "Galloping Consumption," is not more than benefited by the climate of Colorado. All other forms of phthisis become at once the possessors of a new lease on life, except those presenting a condition of general breaking down. As curious as it may seem, and yet the statement can be vouched for by every practitioner in Colorado, patients who, at the expiration of thirty days, have not been benefited by the change of climate, with extremely rare exceptions, would do as well, or better, at their homes; those whose symptoms have subsided even in the least degree at the expiration of the thirty days, with exceptions as rare, either make a complete recovery, or else are so improved as to make life comfortable. The former cases belong almost exclusively to those who have lingered at home under the vain hope of receiving aid by medical treatment. To the other class belong those who have been fortunate enough to fall into the hands of the wise physician, one who possesses that keen intelligence which enables him to recognize his own inability to cope with the disease.

Again, except attention to the digestive organs or to the improvement of other organs of the body which may be affected, those patients coming to Colorado for consumption fare far better when advised only to exercise, diet, and general hygienic laws than those who are drugged. Entrusted as we are with the care of these subjects, a charge more sacred by far than the chance patients we may get, it seems almost inhuman to submit them to all that has failed at their homes. They have been sent to us not to drug, but either to advise them as to the best means of obtaining the benefits of our climate, or to guard them against certain indiscretions they may be apt to commit. It would not take a prophet to foretell the outcome of a case who spends much of his time indoors sifting air through wire meshes saturated with antiseptics, waiting in some close quarter to receive his hypodermatic injection of tuberculin or guiacol, who is fearful lest he might come in contact with fresh air or that the bright sun should mar his complexion, taking into his stomach numerous drugs that very nature would reject were it not for the enfeebled condition of that organ. Nor is much wisdom required to know how he will fare who lets all drugs alone, exercises in the fresh, invigorating air, substitutes for drugs rich milk and well cooked food, who, instead of taking the hypodermatic injection, is sure that just as the food is converted into blood pure air strikes the lungs, that what is left of them may play their part in oxygenating that fluid, that it may course more smoothly and perfectly through its channels, and in its turn perform its proper function in the restoration of diseased parts.

No cure has as yet been accomplished by attempts to destroy tubercle bacilli, and there is every reason to believe that much harm may be done by taking away the excellent advantages afforded by nature to eradicate the disease. It is therefore to be hoped that all physicians, as fortunately many do, will admit their inability to master the disease, and with this in view will advise their patients as to the importance of a speedy change of climate, and the necessity of complying with the general laws of hygiene rather than putting dependence upon the curative effects of drugs.

Pyloric Stenosis.—1. Pyloroplasty, as devised by Heineke-Mikulicz, is the safest and most efficient operation for cicatricial stenosis of the pylorus. 2. Pylorectomy in the treatment of carcinoma of the pylorus is a justifiable procedure when the disease is limited to the organ primarily affected and the patient's general condition furnishes no contra-indication. 3. Gastro-enterostomy by the aid of large, moist, perforated plates of decalcified bone should be resorted to in the treatment of malignant stenosis of the pylorus as soon as a positive diagnosis can be made, and a radical operation is contra-indicated by local or general conditions of the patient. —Senn.

Progress of Medical Science.

Diabetes in a Baby.—Drs. Duflocq and Dauchez report a case of death from diabetic coma in an infant of only eighteen months of age. When Dr. Dauchez first saw the child, on January 6, 1893, he found it had been peevish and uncomfortable for only about a fortnight (*The Practitioner*). It was very thin, weak, and of somewhat venous tint, and its discomforts were attributed by its parents to its teething, but to the doctor's ear the history of constipation sounded more serious. He gave it gentle purgatives and stimulants, and did not attribute any special importance to the mother's statement that it was drinking more than four pints of milk a day. Next day it was much weaker and more cyanotic, and the temperature had sunk to 96° F. More energetic measures were taken; it was wrapped in cotton-wool and given punch, ammonium carbonate, and an enema of coffee. Dr. Duflocq was called in, and found the baby comatose, with lost corneal reflex, quick breathing, and dry tongue. It did not feel the injections of ether, and in a few hours was dead, *i.e.*, in less than thirty-six hours from the time when medical advice was first called in. The possibility of diabetic coma was recognized, and a little further search showed white powdery patches on the napkins and bed-linen, and an abundant amount of glucose by further chemical analysis. Dr. Conolly has recorded (*Medical Times and Gazette*, July, 1874) a very similar case in a child of twenty-one months, with marked constipation ending in sudden coma; and instances have been given by Busch (*Ugeskrift for Læger*, March 25, 1875), Hauner, and Rosenbach (*Berl. klin. Woch.*, 1874), at a still earlier age. In the two last cases, however, death resulted from exhaustion rather than from coma. Hagenbach relates another case where death came on from pulmonary gangrene in a child of six months. There is one case to quote of recovery, in a little baby of Dr. Kitselle's, who was made out by his father within a fortnight of his birth to have diabetes, but who got over it by the time he was eight months old under careful treatment (*Revue de Médecine*, June, 1893).

Treatment of Some Irritable Conditions of the Stomach.—According to Hemic, the cause of cardialgia is spasmodic contraction of the gastric openings, especially the cardiac. Above this there is often a dilatation of œsophagus, in which air and food are enclosed, giving rise to spasm. In dilatation of the stomach and very loose abdominal walls, it may go on without spasm to painful sensations in the cardiac end by traction of the full stomach on the œsophagus, and to collection of air from closure of the cardia after the organ is thus distended. Likewise, as a result of swallowing air, and after the ingestion of certain foods, cardialgia may be produced by undue distention of the stomach. By this immoderate distention cramp at the pylorus may also arise, although with pyloric spasm the distention is usually an effect of the cramp, not the cause of it, the spasm being set up by other conditions, such as irritating contents, especially when increased irritability co-exists of the pyloric portion. For spasmodic cardialgia many remedies have been tried. Subnitrate of bismuth enjoys a great reputation. Morphine acts quickly and strikingly, but temporarily, and leads to lax gastric walls. Gastric pain is produced by irritation of ulcers and sensitive spots in the stomach as well as by spasm. Food or over acidity of the gastric juice excites these places, and pain is the result. If these are supplied with a protective covering, much is done to relieve suffering and encourage healing at the same time. Russmend has recommended subnitrate of bismuth for this purpose. It can be taken in large doses with safety; and as it rapidly falls from watery suspension, it forms a covering for the irritable organ. The method adopted is to wash out the stomach, and pour in ten to twenty grains of bismuth in lukewarm water, and keep the patient at rest for half an hour until it settles; food may then be taken. At first the washing out may be daily; then on alternate days. Toxic symptoms do not arise. The results are excellent, as the troubles even in old and hopeless cases are relieved, and the feeling of improvement continues for several days. That bismuth actually forms a protective covering may be inferred from membranes of that substance seen when the next washing out takes place. It is probable that it is firmly deposited on ulcerated parts, and by its protective action relieves pain and lessens the motor unrest of the stomach and spasms. Over-acidity is diminished, and starchy food is better borne after.—*The Practitioner.*

The Aniline Products in Carcinoma.—In *The Annals of Surgery* Dr. Willy Meyer says: The use of the aniline dyes in the treatment of inoperable carcinoma (malignant growth) generally is "a palliative treatment," no cure. In *very* rare cases this treatment may cure. Carcinoma and sarcoma of hard type (especially the latter) are better influenced than soft ones; those of the soft tissues easier than of the bones; those with a scanty blood supply more successfully than rapidly growing neoplasms with abundant circulation. The disseminated cancer is no object for the aniline treatment. The treatment with parenchymatous injections requires a perfect knowledge and application of the principles of aseptic and antiseptic surgery. If a doctor does not understand them, or can or will not take time to follow them strictly, I should call out to him: "Hands off; do not try it; you must do harm, and will be disappointed; your tumor will soon suppurate and slough, and your patient die of acute or chronic sepsis." Without antisepsis the treatment is bound to harm rather than to do good. It also requires a good deal of patience and perseverance on the part of the surgeon as well as on that of the patient. It will, in the very best case, require a continuous attendance for many weeks or months. On account of the necessary antiseptic precautions, the treatment is time-robbing.

Significance of the Excessive Secretion of Uric Acid.—Dr. Herter believes that the deposition of amorphous urates in a sample of urine is pretty reliable evidence that uric acid is in excess, and the probability of this is increased if the density of the urine is less than 1.025. Unfortunately, we cannot conclude that urine which does not deposit urates does not contain too much uric acid. The early separation of uric acid as such from the urine, however, gives no real reason to think that it is present in actual excess. Every acid urine protected from putrefaction will deposit most of its uric acid in time. As a normal standard, is taken urine in which the proportion of uric acid to urea is about 1.50. When it rises to 1.40 uric acid is to be regarded as being excreted in excess. At 1.35, the excess is to be considered large; 1.30 is a very great excess, and higher than 1.20 is never found. The author regards an excess of uric acid as commonly due to disorders of digestion. Acute disorder of gastric or intestinal digestion temporarily increases it. A very large meal, the use of alcohol, or a large amount of sugar, act in the same way. He regards uric acid as formed by the breaking down of neuclein largely in the liver and spleen. Its excess does not give us information about a particular morbid state or diathesis, but rather indicates the existence of a defect in general nutrition that is, perhaps, commonly induced by the existence in the blood of toxic substances formed during the process of digestion. This being the case, such terms as "uric acid diathesis," and "lithemia," as commonly used, are incorrect and misleading. It does not seem likely that uric acid has much to do with chronic nephritis, since it appears to be rapidly and readily excreted by the kidneys. An increase of uric acid in the urine does not mean that the patient is suffering from the effects of an excess of it in the blood. For patients showing such a tendency, the wisest plan is to continue a mixed diet, in which all classes of food are represented, allowing as much starchy food as is consistent with the avoidance of uric acid excess. The

amount of uric acid excreted gives an objective basis for deciding the value of the line of treatment pursued. If a certain course reduces it to normal, it may be regarded as satisfactory. If, after several days, it fails to do this, it should be changed. It is extremely doubtful whether drugs given to eliminate uric acid really do so. Herter's own experience with piperazine led him to think that the trivial increase in uric acid reached after its use was to be attributed to slight disorders of digestion. He believes we have been attaching a too serious significance to uric acid in its relation to disease, and that the view that it is in any sense a factor in disease, except in a purely mechanical way, is destined to die out wholly.—*New York Medical Journal.*

Operation for Umbilical Hernia on the New-born Child.—M. Berger successfully operated on a female child thirty hours after birth, and exhibited it afterward at a meeting of the Obstetrical and Gynecological Society of Paris. The infant was born strong, breathing well. The umbilical hernia was of the size of a small hen's egg, and covered by the membranes of the cord. There was a distinct neck or pedicle as thick as a man's forefinger, and made up of integument alone, which was united to the membranes by a deep groove. The lower part of the hernia was reducible, and the sac was there transparent. Coils of small intestine showed through it; they could all be pushed back into the abdomen. The upper part was irreducible, and in close relation with the vessels of the cord. After birth the hernia and abdomen were well washed and dressed with iodoform. On the next day the hernial sac was opened, and the small intestine reduced. The irreducible portion consisted of the cæcum, the appendix, and about one-third of the large intestine, all intimately adherent to the membranes of the cord. A layer of these membranes had to be detached and reduced, together with the bowel. This manœuvre could not be done until a free incision had been made along the median line, as in abdominal section. The sac was excised. The peritoneum, the aponeurosis, and the skin were separately sutured. The operation lasted an hour and a quarter. The sutures were removed on the tenth day; recovery was complete at the end of a fortnight. Guéniot, in the discussion on Berger's case, referred to Lindfors' monograph "On Umbilical Hernia," which appeared last January in Volkmann's *Vorträge*. He said that, as in adults, very minute particulars in each case of this operation in infants would be needed. Nothing differed so much as two umbilical herniæ. Other abdominal viscera besides the intestine may lie in the sac, inseparably adherent, and the abdominal cavity may, by congenital defect, be much too small to hold all the herniated structures.—*The Canadian Practitioner.*

Syphilitic Changes in the Blood.—With a view of determining the causes of the paleness of the skin and mucous membrane observed in patients affected by syphilis, especially before the outbreak of the exanthem, and frequently after the lapse of years, Professor Neuman and Dr. A. Konried have systematically examined the blood in 200 cases of syphilis, and in 160 of them this was done repeatedly. The results of the examination were shortly as follows: The quantity of hæmoglobin diminishes even in the first stage fifteen to thirty per cent. The diminution remains constant at the commencement of treatment; with the number of inunctions, or under the use of other anti-syphilitic remedies, the hæmoglobin returns to its normal amount. Older untreated cases of secondary syphilis constantly show a diminution of the hæmoglobin. This diminution varies from forty-five to seventy-five per cent. The action of anti-syphilitic remedies is here plainly observable in the return of the hæmoglobin to a normal quantity. The low amount of hæmoglobin is characteristic of tertian syphilis. Treatment here brought about an improvement in the hæmoglobin, but not to the normal. As regards the red blood-corpuscles, the primary disease did not reduce their number in proportion to the hæmoglobin. With the development of constitutional syphilis they diminished to a third of the normal number; under treatment they returned to the normal. Too large doses of Hg. diminishes them again. Untreated secondary forms invariably showed a diminished number of red blood corpuscles, but treatment restored them to the normal amount. In tertiary forms the average proportion was four millions. There is therefore a diminution, but antiluetic treatment restores them completely, while in the same cases it does not altogether restore the hæmoglobin. The number of white blood corpuscles increases parallel to the diminution in the number of the red, and inversely diminishes with the increase of them. These investigations were to be continued in part *pari passu* with the determination of the specific gravity of the blood, as thereby many of the observations would be widened or completed. According to the views of the authors, for the future the qualities of the blood must be taken into account in regard to the symptomatic of syphilis, as the severity of the disease and the action of remedies will be thereby better judged of and better under control.—*Medical Press.*

Orchidopexy.—Dr. Jalaquier has performed this operation for testicular ectopy fifteen times in thirteen patients. Ten cases were unilateral, inguinal. Two bilateral cases were complicated with hydrocele or hernia. In all these cases there was communication with the peritoneal cavity. The most important point about these cases is the occlusion of the vaginal sheath, not the fixation of the testicle. His results were perfect in twelve patients. The cord always remained somewhat shortened, but the hernia had not been reproduced. The case that failed was in an epileptic child. Dr. Felizet believed testicular ectopy was a complex lesion, and that clinically the defective position of the organ was of secondary importance. There are two great classes of ectopy, the mobile and the fixed. Each has its own therapeutic indications. When the testicle is movable it is ordinarily normal, and the external orifice of the inguinal ring is enlarged. When it is fixed the ectopic gland is valueless. It is painful at times, atrophied, and nearly always associated with a hernia, which does not favor the descent of the organ. In these cases the ectopy and the hernia require treatment, and operative interference is always indicated.—*The Canadian Practitioner.*

Ganglionic Fever.—Dr. Moussons reports two cases of this disease, which was described by Pfeiffer in 1889, and Stark in 1890. The disease is said to occur in children between two and ten years. After a few days of malaise there is a sharp fever, accompanied by restlessness, headache, and vomiting. There is pain on movement of the neck, and difficulty in deglutition. On examination of the sides and back of the neck a great number of engorged glands are discovered; they are tender, moderately enlarged, and are distinct one from the other. Sometimes the enlargement is unilateral, but almost always it is bilateral; sometimes the submaxillary region is also involved. After a few days all the symptoms are less intense, a little fever may persist with hacking cough, some pain in the abdomen in the region of the umbilicus; finally there is obstinate constipation. One recognizes at once the enlargement of the lateral and posterior cervical glands, while those of the axilla and groin are normal. The liver and spleen may be slightly enlarged. There is often great emaciation and loss of strength. The author has noted in his cases some prolongation of the breath-sounds. In his case there was a distressing cough, which, with change in the breath-sounds, was supposed to be due to enlargement of the peritracheal glands. The cause of the disease is unknown. Stark believed it to be directly due to constipation, which favored the absorption of toxic material from the intestinal canal.—*University Medical Magazine.*

Clinical Department.

A CASE OF MYXŒDEMA WITH UNUSUAL FEATURES AND RAPID RECOVERY.

By R. B. KIMBALL, M.D.,
NEW YORK.

THE following case, that came under my observation during the past summer, seems to me to present two features of unusual interest.

1. The intercurrence of an acute and very extensive disturbance of the skin, apparently a vaso-motor neurosis, which appeared suddenly, persisted about four weeks, and disappeared in a few hours after the beginning of the thyroid treatment.

2. The extreme rapidity with which the myxœdemic symptoms disappeared under treatment, and the seeming completeness of the cure.

The patient was a woman fifty-five years of age, quite stout. Had borne four children, and always enjoyed good health until after the change of life. Since she attained her fiftieth year has been ailing continually, much of the time in bed. During this period of five years the hair has completely disappeared from her body. Her skin has become remarkably thickened and its sensibility impaired. She has never perspired at all. Her mental condition has undergone gradual deterioration. She has suffered constantly from dyspepsia and neuralgia, is hypochondriacal and suspicious. In fact, her life has been a burden to herself and her family.

I saw her for the first time July 18th. She had then an extensive discoloration of the skin that had appeared suddenly two weeks before and gradually increased in area and severity. Her limbs, chiefly in the extensor surfaces, were covered with large red blotches which were painful and sensitive. The entire extremities were much swollen. These spots came suddenly with burning and tingling sensations, were at first of a livid red, and gradually became purple and blue as they faded away, to be replaced by others. There was no rise of temperature, no general disturbance. The condition was not unlike Raynaud's disease, though it fell short of it in intensity. There was no gangrene. This condition grew steadily worse until the beginning of the thyroid treatment, July 18th. At that time her condition was as follows: She had no hair at all. Her scalp was dry and scaly. Her skin had a yellowish, waxy look, with red spots on each cheek. It was everywhere enormously thickened. This infiltration was especially noticeable about the eyes. These seemed half closed all the time, and this effect was heightened by the redundant overhanging eyelids and the curious elevation of the eyebrows. Her ears were massive, and protruded far out from her head. Her lips were very thick, and her tongue seemed doubled in size, and was protruded slowly and with difficulty. Her hands were so swollen that she could not approximate the fingers, and she used them awkwardly. Her speech was slow and drawling, and she often stopped in the midst of a sentence and forgot what she was talking about. She complained constantly of cold. The sensibility of the skin was greatly diminished—this was a most striking symptom. Flies would alight upon her face and crawl about entirely unheeded, and she had twice been severely burned with mustard without feeling the pain. Her digestion was very poor, entire loss of appetite, and all solid food distressed her so that she subsisted almost entirely on milk. All her acts were performed slowly and listlessly, and her whole appearance was suggestive of apathy and stupidity. She spent most of her time in bed swathed in flannels, seldom ventured out of doors, and never walked. Her mental condition was weak. She was slow of comprehension, querulous, obstinate, and suspicious of every one about her. Her temperature was subnormal, and averaged about 97⅘° F.; pulse about 100. Her urine, which was examined twice, was negative, except a very low specific gravity, 1002 to 1004. Daily quantity was not measured, though it did not seem immoderate.

Treatment was begun August 2d. The thyroids were administered in the form of capsules containing five grains each. She took three the first day, one after each meal. During the evening she had a violent chill, and at 9.30 P.M. her temperature was 103° F., with headache and vomiting. Temperature subsided gradually during the following day.

August 4th.—But one capsule was given.

August 5th.—She took one morning and evening.

August 6th.—She again took one after each meal.

No further febrile reaction occurred, but throughout the entire duration of the active treatment she suffered from nausea, indigestion, and extreme nervous irritability. On this account it was several times necessary to omit or diminish the capsules for a day.

It is curious to note that the vaso motor phenomena vanished immediately after the febrile reaction of August 2d. No new spots appeared, and those already existing faded rapidly away.

At the end of one week (August 9th) the effect of the treatment was already apparent. Patient looks thinner in the face and perspires slightly about the neck.

At the end of second week (August 16th) facial expression much changed. Natural lines about the face and hands beginning to reappear. There is a perceptible growth of new brown hair in the eyebrows. Perspires freely about the head and neck. Rapid absorption about the eyes makes them appear much larger. Pulse, 105; temperature, 98° F.

End of third week (August 23d). Patient has emaciated wonderfully. Looks haggard. Perspiration profuse. Face and hands look wrinkled, and expression entirely changed. Complains of nausea and diarrhœa; seems very weak and nervous. Thyroid capsules reduced to two a day. Prescribed strophanthus, 5 drops, strychnia sulph., gr. $\frac{1}{60}$, and milk punches three times a day.

September 4th.—Patient still weak and nervous. Has apparently lost fifty pounds. Skin seems soft and moist. Thickening noticeable only in ears and tongue, and slightly about eyes. Speech and ideas much more fluent. Nausea and diarrhœa not so marked, but still present. Reduced capsules to two every other day.

September 13th.—Patient returned to her home in New York City. Has greatly improved in strength and vigor since last reduction. Has been out to drive twice; walks down-stairs every day. The change in her appearance is startling, now that she is dressed. Her clothes hang loosely about her. Fine growth of new hair beginning to appear all over the scalp. Pulse about 90; digestion and appetite beginning to mend. Discontinued strophanthus and strychnia, and prescribed Fraser's chamomilla comp., ℥j, t.i.d. before meals. Still taking two thyroid capsules every other day.

September 22d.—I saw her in town. Patient was sitting at a second story window as I drove up, and came quickly down stairs to meet me. She looks very well and is vivacious and chatty. Has good appetite, sleeps well, can eat solid food. Hair has grown luxuriantly, and is one-fourth of an inch long. Pulse, 85; temperature, 98° F. Specific gravity of urine, 1020. Number of capsules reduced to two per week.

November 13th.—Saw patient after lapse of seven weeks. She seems perfectly well, is strong and ruddy, talks volubly, with no suggestion of her former drawl. Her family say that she is cheerful and amiable. Attends to her household duties. Walks about a mile every pleasant day. Has been down-town shopping (from Eighty-ninth Street) several times, and has taken a railway journey of thirty miles alone. Her hair is over an inch in length and is very thick. Eats everything, and is hungry except after taking the capsules. Pulse, 80. I could discover no trace of her myxœdema. In fact, she looks and acts like any healthy and contented woman of fifty-five. Advised her to take but one capsule a week.

December 7th.—Patient still perfectly well. Has taken no thyroids for two weeks.

24 EAST FORTY-FIRST STREET.

SUPPRESSION OF URINE FOR TWELVE DAYS, WITH RECOVERY.

By JOHN W. ROSS, M.D.,

U. S. NAVAL HOSPITAL, PENSACOLA, FLA.

Hilary W——, white, aged ten, schoolboy, resident of Milton, Fla., came to me from Dr. Judge, of Milton, Tuesday, December 23, 1890. Had not urinated since the preceding Thursday, December 18th, suppression having come on during an attack of fever, probably malarial. Dr. Judge had used the catheter frequently during that time, but had found no urine in the bladder.

I also found the bladder empty, and it remained so until December 30th, when a pint of urine of low specific gravity, but otherwise normal, was voided by the patient.

In the interval there existed marked anæmia and the usual symptoms, though in a mild degree, of uræmic intoxication. There was extreme nervousness, and convulsions seemed frequently imminent, but no explosion occurred.

The treatment was perfect quiet in bed between blankets, constant rubefaction over the loins, diaphoresis, mild catharsis with calomel and salines, and milk diet. The reappearance of the renal secretion was shortly preceded by the occurrence of slight ptyalism.

Recovery was gradual, but uninterrupted, and in two months the patient was at school in his usual health. His mother stated that he had all his life had occasional brief periods of trouble with his kidneys, during which the urine would be scanty.

He continued in fair health for nearly three years, but died the latter part of September, 1893, of acute nephritis, apparently the sequel of malarial fever. During a visit to Milton I saw him once in his last illness, but found him moribund.

A PLEA FOR THE SLOW AND GRADUAL EXHIBITION OF ANÆSTHETICS UNTIL THE "FIRST STAGE," OR STAGE OF EXCITEMENT, HAS BEEN PASSED.

By JOHN B. RICHARDSON, M.D.,

LOUISVILLE, KY.

In your esteemed New York Medical Record of October 28, 1893, pp. 573 and 574, there appeared an article by Dr. A. M. Adsit, of Hastings, Mich., which well deserves to be written in enduring letters of gold upon the minds and memories of all physicians and surgeons—and this mode of administration should be emphasized by all teachers in our colleges—concerning the only proper and humane manner of administering anæsthetics.

For any one to speak of that "whereof he knows" he must have had personal experience, not in anæsthetizing others only, but having had another place him under the influence of an anæsthetic.

From my reading, experience (of thirty years), and interchange of opinion touching this subject, I am positive that a very large majority of my professional brethren deem it essential—more especially in the administration of ether as an anæsthetic—for the immediate and remote safety of his subject, that he must produce anæsthesia as rapidly as possible. This is almost tantamount to asphyxiation.

Dr. Adsit very truly says: "To avoid these bad effects (the initial disturbance of inspiration, preventing the proper aëration of the blood, and, as a result, we have the flushed face, the distended veins, the coughing, the jerky, catching respiration, and I add, that horrible dyspnœa, and its concomitant sensation, that you are powerless to exhale the irritating ether vapors already inhaled, and the feeling that your heart will burst from over distention, the increased flow of mucus, and the wild struggle for liberty), two rules must be observed: 1st, begin the administration with air lightly charged with ether; 2d, always permit all the air necessary to sustain life comfortably." Physicians seem to forget that neither chloroform, ether, nor any other anæsthetic can be substituted for air. "There is no good reason why a patient does not require as much air while taking an anæsthetic as at any other time. If you think that they secure the needed supply of air, place a cone over your own face and permit some one to hold it down tightly for five minutes."

Now this is not overdrawn, for I would much prefer the cone being pressed down tightly upon my face for five minutes, and take my chances for the small amount of atmospherical air, than to have that modicum surcharged with the vapor of ether or chloroform.

All of us probably have at times been able to anæsthetize children while asleep, but to enable us to do so, we had to dilute the anæsthetic with air freely at first, and administer it slowly, gradually increasing its strength, that no disturbance of the patient should occur.

If in thus seconding the mode of slow and gradual exhibition of anæsthetics—which my personal experience enables me to do—I shall influence some of my brethren to substitute this method for the rapid and sudden manner generally employed, and shall thereby save some poor mortals this greater suffering and shock than at times the operation performed proves to be, I shall not have pleaded in vain.

A CASE OF PAINLESS LABOR.

By THOMAS J. LARKIN, M.D.,

NEW YORK.

On November 24th I attended a case of labor, the conditions of which I have deemed sufficiently notable to report.

The patient, Mrs. M——, aged twenty-nine years, was a large woman weighing over two hundred pounds. She was the mother of three children, and gave the history of her former labors thus: First child was born in twenty minutes from the time of first pain; second labor lasted three hours, and the third two and a half hours. None of the previous labors had been protracted, but all had been accompanied by the usual sensation of pain.

The children, aged five years, three years, and thirteen months, respectively, are all living. Upon my arrival at the house, at 10 P.M., she complained of feeling nervous and announced that "the waters had broken at 9.30," but she had no pains. During the previous day she had had a pain in the back which lasted but a short time and disappeared after the application of camphorated oil. Upon examination I found the os dilated to the size of a silver dollar and the head in the median line. After waiting thirty minutes, during which time there had been no pain experienced by the patient and no sign of uterine contraction, a second examination discovered the cervix obliterated and the head in the vagina. Fifteen minutes later, at 10.45, the child, a boy weighing ten pounds, was born, the placenta following in ten minutes.

At no time during the labor had there been any sensation of pain, nor could the most careful palpation detect any evidence of uterine contraction. The thickness of the adipose tissue upon the abdomen prevented the most thorough uterine palpation; the after-history of the case was uneventful except for a complete relaxation of the uterus, which caused the fundus to ascend higher than the umbilicus. This was unaccompanied by flooding, however, and was overcome by strychnine sulphate, grain $\frac{1}{60}$, three times a day. The complete absence of pain and apparent absence of uterine contraction render the case noteworthy.

There was no loss of sensation in any other part of the body.

Inunction in syphilis is attended with an evaporation from the rubbed-in mercury, which is later on absorbed through the skin and by the lungs in considerable quantity. If an energetic action is desired, a portion of the ointment should remain smeared upon the surface.—Welander.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, December 23, 1893.

"CENTRAL SUPERVISION" OF THE STATE HOSPITALS.

THE policy which the Lunacy Commission is pursuing will, if followed to its logical conclusion, result in the subordination of the State Hospitals to political control, and thus accomplish their inevitable ruin. From the first the Commission has proceeded along lines laid down many years ago by a coterie of politicians whose purpose and aim have been to bring all the departments of the public service of the State under their centralized management. This policy was boldly announced by the Commission, soon after it had begun active work, in the following terms: "The Commission does not hesitate to affirm, that in its deliberate judgment no great and enduring improvement in the management can reasonably be looked for until they (the State Hospitals) are put under more effective and thorough central supervision by the State than now obtains." The argument by which this proposition is sustained is based on the change in the management of the prisons and canals by which a single officer was invested with powers that the Commission declares are "so absolute that not even the Legislature can interfere . . . with their (his) appointment of subordinates." In anticipation of the enormous power which it would wield, and the immense patronage at its disposal should its policy of centralization succeed, the Commission declares that the interests concentrated in these hospitals "in the number of persons employed . . . rivals the canals and the schools, . . . surpasses by far the State prisons."

This is a prize which the politicians had long eagerly sought to grasp before the creation of the Commission, but the local Boards of Trustees, the superintendents, and the State Board of Charities, have stood as impregnable barriers to the accomplishment of their purposes. Even the original law organizing the Lunacy Commission was carefully drawn to protect the hospitals from the exercise of any executive control in their management by that body. In this respect the law closely followed the English Lunacy Commission Act, which, for nearly half a century has given to England the best administration of her institutions for the insane of any civilized country. Repeated efforts have been made to induce the English Commission to obtain from Parliament a centralization of executive powers in the management of the asylums, but it has steadily refused. The Earl of Shaftesbury, who originated the Act, and who was Chairman of the Commission for upward of a score and a half of years, always maintained that the usefulness of the Commission depended entirely upon its lack of power, and to the fact that its duties consisted in constant visitation of asylums and exhaustive inquiries into the management, with friendly advice and aid.

Though the projectors of the law creating the Lunacy Commission of this State were governed by the conservative opinions which have made lunacy administration so successful in England, the Commission created by the law was from the first inspired with the idea that reforms in the management of the hospitals could not be effected through the local Boards by friendly advice and assistance, but must be accomplished by its own assumption of executive powers. Instead of immediately making an exhaustive examination of all the institutions in order to discover defects of management, and attempt to remedy them by advice and friendly co operation, the first notable act of the Commission was to secure an amendment of the entire law. There are three noticeable features in the amended law, viz.: 1. The salaries of the Commissioners, already liberal, were considerably raised. 2. The regular and systematic visitation of hospitals, made statutory as in the English Act, were made discretionary, the reason of this change, as given by the Commission, being that the individual Commissioners had not the physical ability to make the required visits. 3. A much more simple and direct method of enforcing the orders of the Commission upon the hospital management. By these amendments the objects sought to be attained by the original law were largely nullified or perverted, and the first step in the direction of "central supervision" was taken. The physical inability of the Commission to make inspections became evident when left to their discretion, while the peremptory orders issued from the central office proved that their energies were diverted to another sphere of activity.

The passage of the State Care Act added to the power of the Commission, and the policy of "central supervision" was finally consummated by the Act of the last Legislature providing the necessary appropriations for the care of the transferred pauper insane. That law gave the Lunacy Commission full power to revise the monthly estimates of the asylums, and thereby not only to enter directly into the details of their management, but absolutely to control their operations. Practically, the local Boards are ignored, and the superintendents are brought into the most abject subordination to the central authority at the Capital. The last stage in the policy of "central supervision" of the State Hospitals, in accordance with the precedent of the prisons and canals, so highly commended by the Commission, will be the reduction of its numbers from three to one, and that one must be a partisan politician. This is the logical conclusion of the policy which the Commission has declared to the people of the State that it approves, has inaugurated, and is now zealously following. Admitting that the present Commission is composed of men who will wisely exercise their power and jealously preserve the State Hospitals from the contamination of political influences, the history of centralized power at Albany shows conclusively that sooner or later it brings disaster to the interest which comes under its control. It remains for the Legislature to determine how far the policy of "central supervision" of the

State Hospitals, under the plausible guise of economy, shall proceed to intrench itself in our State system of supervision of public charities. While we heartily approve of State supervision of the institutions for the Insane, as provided by the law of 1889, which also brought into existence the Lunacy Commission, we earnestly recommend that such duties be conferred upon a conservative body which can be relied on to build up and strengthen the institutions of the State, rather than to make them the medium through which it seeks to gain power and patronage.

THE HEALTH DEPARTMENT AND PULMONARY TUBERCULOSIS.

The recent decision of the New York City Health Board to adopt measures for the restriction and prevention of pulmonary tuberculosis deserves the commendation and earnest support of the medical profession. Although the communicable character of this disease has now been recognized for more than ten years, not until recently has its general acceptance by the profession justified sanitary authorities in taking active measures for its prevention.

While tuberculosis is an infectious disease, yet it differs so radically in nature from most other infectious diseases that a large proportion of the medical profession, although accepting the experimental proof of its infectiousness, have felt that more harm than good would be produced by the official and public declaration of its nature by sanitary authorities. The time has come, however, when this objection can no longer be considered as valid, and the action of the Health Department, in officially declaring it to be a communicable disease and in adopting measures for its prevention and restriction, must be considered as a step thoroughly justified and in harmony with the best public policy. The importance of this action cannot be over-estimated, for not only do we trust there is good reason to believe it will result in the course of a few years in a decided diminution in the number of cases of pulmonary tuberculosis in New York City, but the action of the New York Health Board is likely to be followed by sanitary authorities in other towns and cities throughout this country.

The work as determined upon is understood to be largely educational in character and preliminary to the adoption later of a more comprehensive scheme for dealing with this disease. The exact scope may be determined from the preamble and resolutions offered by Commissioner Edson and adopted by the Board, which are to be found on another page of this issue.

These were based on a report recently made to the Board on the subject of pulmonary tuberculosis and the importance of its prevention by Dr. Hermann M. Biggs, the pathologist of the department.

Whatever may have been the feeling of the medical profession in the past regarding the Health Department and its work, justice requires that after a review of the work for the last year, which includes the successful management of an outbreak of cholera in the fall of 1892, the stamping out of an epidemic of typhus fever in the winter of 1892–93, the developing of a scheme for the systematic bacteriological diagnosis of diphtheria, the successful limitation of an outbreak of small-pox in the fall of 1893 and last, but not least, the measures recently adopted for the prevention of tuberculosis, the profession should accord due credit to it for having taken a most advanced stand regarding the diagnosis, management, and general sanitary surveillance of contagious disease.

DO THE SICK EVER SNEEZE?

For somewhat over twelve months the readers of medical literature have been confronted in small caps with the conundrum: "Do the Sick Ever Sneeze?" We do not know why this inquiry has become so popular; no prize has been attached to its proper answer; in fact, comments and replies are not even solicited. But the simple query has been travelling around from Sheffield and London to Texas, Oregon, and Philadelphia, and it has not been answered yet. There are some problems which the human mind shrinks from grappling, sometimes because they are too deep, and too consuming, or again, because we dread the consequences of an awful certainty. No medical man has yet dared to come out squarely and say in so many words that the sick do or do not sneeze; and the world is curious to know whether this is due to fear or incompetency; or is it that doctors simply do not know?

Perhaps despite the fact that this question—which was first thrown upon the world by Mr. Jonathan Hutchinson, the greatest living authority on a number of things—we say despite the fact that this question has been so continually pressed home to students of medical science, it may not yet have made the impression it ought. There is a deal of flippancy in the world and some may have said on reading the inquiry: supposing the sick do sneeze, or do not, what the dickens is the odds? Well, we shall still have cakes and ale irrespective of sternutation, but science exists for the purpose of adding to the eternal verities; hence, the question of sneezing must be dealt with seriously and answered in accordance with the illumination furnished by thorough and matured knowledge. It cannot be lightly thrust away by appealing to points of economics.

We are aware that collective investigation is a little out of fashion, but here is an opportunity for fruitful work, and we should like to have our readers lay aside mental indolence and address themselves boldly to Mr. Hutchinson's problem in hyperkinetics: "Do the Sick Ever Sneeze?" The eminent author himself has never seen a sick man sneeze; on the other hand we venture to say that we have never seen a man sneeze who thought he was perfectly well. Between these wide ranges of experience there lie rich fields, fructifying study.

THE TEXAS DYSENTERY CURE.

Down in Texas there is some excitement and hopeful anticipation over the supposed discovery of a new and sure cure for dysentery. Dr. R. T. Knox, of Gonzales, tells about it in the *Texas Medical Journal*. He had himself suffered from this malady for three years and had tried many things in vain. He had become reduced from one hundred and ninety-six pounds to one hundred and forty-two. Irrigation, hydrastin, lactopeptin, bismuth, opium, salol, petroleum, silver, milk, fish, roast potato, and infant foods, were all useless. Horse-radish root chewed and the juices swallowed did the most good. Finally a

farmer advised him to try the infusion of a shrub known as Bisbiranda armagosa or chappero bush, which had much repute among the Mexicans. He tried it and began to get well, in two weeks he was convalescent and he was eventually cured. The journal reports two other cases cured and expects to add to the list soon.

We trust that the chappero will turn out to be all that is expected. The records of clinical medicine, however, are full of cases of apparently hopeless dysentery cured by very different agents. One should read the autobiography of Dr. Marion Sims to appreciate this fact.

THE TEMPERAMENTS.

It is interesting to find that so thoroughly scientific a man as Professor William Preyer has adopted the four-fold classification of temperaments made nearly two thousand years ago, namely, the choleric, sanguine, melancholy, and lymphatic. The existence of one or the other of these temperaments may be discerned, he says in his work on "The Infant Mind," very early in the great majority of children—in the second quarter of the first year, beyond a doubt.

Nearly every one who has written about temperaments has gotten up a classification of his own, Galen had nine, Haycock gave six, Graham Brown, seven, and others have got down as low as two. Modern writers use the word nervous for choleric and bilious for melancholic temperament. With these verbal modifications the old classification seems to answer all practical purposes, and individuals can build up combinations as needed.

Hutchinson defines temperament as the sum of the physical peculiarities of a man exclusive of his tendency to disease. This is not very satisfactory, though, perhaps, temperament is a thing a little too vague to be satisfactorily defined. In modern terms it may be said to be the peculiar way in which the individual reacts to the stimuli of his environment. There is no doubt that one class of persons reacts quickly and easily, expending energy profusely and often needlessly in their life work; others react hopefully and work buoyantly yet with less waste. We can thus distinguish the nervous, the sanguine, the melancholic, etc. A capacity to recognize and appreciate the importance of temperament used to be considered part of a sound medical training. It has been too much neglected in our pursuit of minutiæ with microscopes and test-tubes. Our teachers of practical medicine might well revive its study.

DOES EXALGINE POSSESS LOCAL ANÆSTHETIC PROPERTIES?

Exalgine is a derivative from acetanilid, made by the substitution, for one hydrogen atom of the latter, of the methyl group CH_3. Both have the same general power to lessen painful sensation, and to lower bodily temperature. In a recent number of the *Bulletin Médical du Nord*, Combemale gives the result of a series of experiments made to ascertain whether or not exalgine possesses any local anæsthetic power.

The experiments were made upon six dogs and one guinea-pig. The solution used consisted of exalgine, one gramme; alcohol, five grammes; and distilled water, twenty grammes. It was placed in the conjunctival sac, in the nares, and injected into the subcutaneous cellular tissue in the proportion of two milligrammes for every twenty centigrammes of bodily weight. The sensibility of the skin and mucous membranes with which the remedy had been brought in contact was tested immediately and during the half-hour succeeding the injections.

In general terms the results were as follows: In all cases, no matter what the avenue of introduction, the quantity of saliva was greatly increased. There was no constancy in the effect on the conjunctiva above the uniform congestion. In some instances the corneal sensibility was somewhat lessened. The dimensions and mobility of the pupil did not appear to be at all influenced. The effect seemed to appear far more quickly from instillation into the nares than into the conjunctival sac.

Combemale concludes that the remedy has a definite anæsthetic action, but that it is very small in degree and very transitory. It may be sufficient for exploratory manœuvres and for momentary operations.

News of the Week.

The Return of the Grip.—The prevailing despondency and stringency in medical circles might be somewhat relieved by a vigorous prevalence of the grip. Yet physicians do not anticipate its coming with any less alarm than other classes. For the grip seems to take a particular fancy to doctors, and to lay them up to a disastrous extent.

The Murderer of Mayor Harrison, Prendergast, is considered insane by most of the alienist experts of Chicago who have examined him.

Sir Andrew Clark's Will.—The will of Sir Andrew Clark, who died a few weeks ago, disposes of a property worth $1,021,000. A legacy of $2,500 is to be used in founding a medical scholarship at the London Hospital. The rest is to be distributed in the family. Sir Andrew started life as a poor boy, and died a millionaire. His income for many years was very large, yet it is difficult to believe that any physician can earn a million of dollars by professional work alone.

The Profession and Managing Boards.—Referring to the criticisms that have been made of the New York Infant Asylum Managers recently, the *Post-Graduate* says: The profession ought to have an aggressive and defensive union against hospital managers that behave in this way; but how to remedy the condition of things until the profession respects itself and refuses to take places that other men have resigned on account of bad treatment, we cannot say. It is a vast question, this of the relation of medical boards to boards of managers. In some hospitals it is solved by having the doctors on the board with equal powers with their fellows. This, we think, is the happiest solution. Men cease to quarrel with each other, if they are gentlemen, when they sit down face to face with equal rights, but separate them and let accounts of what the others think and do, come as rumors, or exist only in suspicions, and difficulty is inevitable.

The Academy and Politics.—Pretty soon it will be said that the Academy is going into politics, when it recommends that vaccination shall be enforced by law, or that school-houses be ventilated. This great fear of poli-

tics invading scientific bodies sometimes comes from men who are engaged in personal and "peanut" politics of the first order. There is no danger that the Academy of Medicine will ever engage in anything like partisan politics, but attention to the higher hygienic sanitary and medical matters pertaining to the commonwealth it must give, or sink to the position of being an asylum for decayed essayists on "The Virtues of Vegetable Extracts," and "The Significance of Supernumerary Toes."—*Post-Graduate.*

The Bill to Regulate Medical Practice in the State of Georgia has failed to become a law. It was defeated chiefly through the agency of eclectics. Georgia has been a particularly fertile field for cheap medical schools and cheap doctors. The State has now at least five medical schools, and in its history are the records of seven others which have lived a variable period.

The First State Hospital for Epileptics.—Thanksgiving-day was observed with peculiar appropriateness in the little town of Gallipolis, in the southern part of Ohio, for the day marked the opening of the State Hospital for Epileptics, the first of its kind in this country.

The Next Meeting of the American Medical Association will be held at San Francisco, on the first Tuesday in June, 1894, instead of on the first Tuesday in May, in order to permit of a discussion of the Code by the various State Societies that meet just before the meeting of the National Association.

Tufts College Medical School.—This new venture, in Boston, is designed for both male and female students. The first year's class contains over seventy pupils. The school has temporary quarters at No. 188 Boylston Street.

St. Luke's Hospital.—Dr. Van Horne Norrie has been appointed an attending physician, to succeed Dr. George L. Peabody.

The End of an Uncalled-for Action at Law.—Last Saturday Commissioner Fairchild, sitting in Buffalo, dismissed an action that had been brought by Mr. Anthony Comstock, against a firm engaged in the manufacture of surgical tables, for having sent through the mails circulars illustrating their wares by means of pictures showing nude persons in various attitudes on their tables. We are informed that these delineations are reproductions of those published in the reading-matter of different reputable medical journals, and that the circulars are sent to members of the medical profession only. That being the case, it does not seem to us that Mr. Comstock was justified in his attempt to suppress them.

The Revolt of the Brazilian Medical Staff.—The entire medical staff of the Brazilian navy, which has been loyal up to the present time, has joined the forces of the insurgents and placed itself under the orders of Admiral Gama.

Bequest for a New Hospital.—The late Mrs. Johnson, of San Francisco, has bequeathed the sum of $6,500,000 to found a free hospital in that city. The money is in the charge of Archbishop Riogan.

Vacancies on the House Staff at the Woman's Hospital.—A competitive examination of candidates for positions on the House Staff of the above Institution will be held at the Hospital, Forty-ninth Street and Fourth Avenue, on Thursday, January 11th, at 3.30 P.M. Gentlemen wishing to present themselves will address Bache Emmett, M.D., 18 East Thirtieth Street, New York.

Dartmouth Medical College, New Hampshire.—The following appointments have been made: George A. Leland, M.D., of Boston, Professor of Laryngology, in place of F. H. Hooper, M.D., deceased; Tilghman M. Ballist, M.D., of Philadelphia, Professor of Therapeutics, in place of H. M. Field, M.D., resigned; Gilman D. Frost, M.D., of Hanover, Professor of Anatomy, in place of L. B. How, M.D., deceased.

Dr. G. Baumgarten writes: "A short paragraph has just come to my notice in your issue of October 14, 1893, page 512, concerning a 'Dr. Jacob Hartmann, of St. Louis Medical College.' There is no such person connected with the St. Louis Medical College."

"**Grip of the Abdominal Type,**" says Dr. H. F. Eichacker, of this city, "prevails quite extensively among the children of the poorer classes. The main symptoms are abnormal high temperatures—103 to 105° F., with anorexia and decided meteorismus, no pulmonary disturbances. The onset is always sudden. The disease usually lasts from five to eight days, and ends in a mild bronchitis."

The Late Dr. William F. Hutchinson.—At a meeting of the Executive Council of the American Electro-Therapeutical Association, the following resolutions on the death of Dr. William F. Hutchinson, of Providence, R. I., were unanimously adopted:

Whereas, It becomes our painful duty to announce the death of Dr. William F. Hutchinson, one of the Foundation Fellows of the American Electro-Therapeutic Association as well as the First Vice-President of the same, and

Whereas, in his death we lose a warm and faithful friend, a valued associate, and an accomplished member of the profession, therefore be it

Resolved: That this Association desires to place on record its appreciation of his genial spirit, his active co-operation in the work of the Association, and of his deep interest in the scientific questions of his chosen profession.

Resolved: That we express our sincere regret and heartfelt sorrow at his death.

Resolved: That we tender to his sorrowing family an expression of our profound sympathy in their great loss.

Resolved: That a copy of these resolutions be sent to the bereaved family, to the medical journals, and that they be spread upon the minutes of the Association.

AUGUSTIN H. GOELET, M.D.,
W. J. MORTON, M.D.,
G. BETTON MASSEY, M.D.,
ROBERT NEWMAN, M.D.,
CHARLES R. DICKSON, M.D.,
Executive Council.

Four Full Courses in the Rush Medical College.—The trustees and faculty of Rush Medical College have given notice to the Secretary of the American Medical College Association that at the next meeting they will introduce a resolution requiring all students who begin their studies in the fall of 1895, to attend four full courses

of lectures in the Medical College, of not less than six months each, providing that graduates of all literary and scientific colleges of good standing shall be allowed to graduate in three years, and providing that graduates of dental colleges requiring three full years of study may be allowed to graduate in two years, and that graduates of dental and pharmaceutical colleges requiring only two years of study, may be allowed to graduate in three years in the medical college.

Dr. L. Younghusband has been appointed a member of the Board of Health of Detroit.

Liability of a Physician for Selling Intoxicating Liquors in Iowa.—The Iowa statute which prohibits the sale of intoxicating liquors, makes an exception in favor of licensed physicians, permitting them to dispense, in good faith, such liquors as medicine to patients actually sick and under their treatment at the time of such dispensing. The defendant in the case of State *v.* Field, decided by the Supreme Court of Iowa, October 5, 1893, was a physician and kept a drug-store. The evidence showed that people would go to his store and ask for "red medicine," which meant whiskey, or "white medicine," which meant alcohol, and obtain it. The theory of the defence was that whatever was obtained was prescribed by the dispenser as medicine. The trial court instructed the jury that if it found that the liquor was sold and dispensed, as by a physician to patients actually sick and under his treatment, to acquit. This the Supreme Court said was a correct statement of the law as applicable to such a case, and that it would not be correct to add to the charge the clause, "or whom the doctor believed to be actually sick."—*Journal of American Medical Association.*

New York's Laws for the Insane.—The laws of New York and Massachusetts have placed those States in the foremost rank of intelligent and liberal care for the insane. The enactments regulating the commitment to asylums, and the care while there, of the insane, and especially the State Care act of New York, have been in the main wise and beneficent. The weak point in the New York law is that a plan for centralizing in a State Commission power as to details of management of the hospitals, which was overwhelmingly defeated in the Massachusetts Legislature, has become part of the New York statute, and that the Lunacy Commission, which ought to be a purely supervising and advisory board, has executive functions which are not only needlessly vexatious to the hospital managers and medical officers, and prejudicial to the interests of their patients, but also may be destructive of good morals. The managers and medical officers of the hospitals for the insane have taken courage from the political upheaval in their State, and are attempting a reform, in which we wish them every success.—*Boston Medical and Surgical Journal.*

Royal College of Physicians.—Dr. Russell Reynolds has succeeded Sir Andrew Clark as President of the Royal College of Physicians.

A Congress of Quacks.—A motley assembly, claiming to be a "National Congress for the Free Practice of Medicine," met in Paris on November 20th. All sorts and conditions of irregular practitioners—*masseurs*, magnetizers, faith-healers, bone-setters, *et hoc genus omne*—were invited to take part in the proceedings, the only essential condition of membership apparently being the fact of being engaged in the practice of the healing art without a legal qualification. In such a gathering the possessor of a regular diploma would have been as much out of place as the *testiculi sibi conscius mus* in the temple of the Bona Dea. Unfortunately, no report of the proceedings has reached us, but it is not difficult to imagine the nature and general drift of the discussions. A special feature of the "Congress" was that patients who had been cured by members of the unqualified fraternity were invited to come forward and recount their experiences, for all the world like the brands snatched from the burning at a revival meeting. When the Greek philosopher Bion had his attention called to the votive offerings of persons who believed themselves to have been saved from shipwreck by the power of the gods, he answered, "But where is the list of those who were drowned?" The moral of which remark lies, as Jack Bunsby would say, "in the application of it."—*British Medical Journal.*

The Presbyterian Hospital Refused to Send an Ambulance.—The refusal of an attendant in the office of the Presbyterian Hospital to allow one of the hospital ambulances to convey the Rev. Charles N. Douglas, the assistant rector of the Church of the Redeemer, Park Avenue and Eighty-second Street, to St. Luke's Hospital, December 15th, may result in Mr. Douglas's death. He was at the church Friday evening. In the middle of the choir rehearsal, at 9.30 o'clock, he was suddenly seized with a coughing fit, and, sinking into a chair, had a hemorrhage. Mr. Douglas was carried into the vestry, and the Rev. W. Everett Johnson, the rector, and Dr. J. B. White, of 1013 Madison Avenue, soon arrived. Dr. White pronounced the case pleuro-pneumonia, and he urged that the patient be taken to a hospital with all possible haste. Mr. Johnson telephoned to St. Luke's Hospital, but as that institution did not have an ambulance at its immediate disposal, Mr. Johnson telephoned to the Presbyterian Hospital. The attendant who answered the telephone curtly replied to the request for an ambulance to convey a patient to St. Luke's Hospital with a "Certainly not." He said that they would send an ambulance if the patient was to be brought to the Presbyterian Hospital. Mr. Johnson would not consent to this, but Mr. Douglas's condition was getting worse, and finally it was decided to send him to the Presbyterian Hospital. About one o'clock in the morning the ambulance arrived, and Mr. Douglas is now in a serious condition in the hospital. A *Tribune* reporter saw the attendant last night who answered Mr. Johnston's telephone calls. He said: "Certainly I refused to allow one of our ambulances to be used to carry a patient to St. Luke's Hospital. What do the people think we are? A public institution? Not a bit of it; this is a private hospital." He did not consider the possible propriety of criticism upon the refusal of the Presbyterian Hospital to give the use of one of its unemployed ambulances to the Episcopal St. Luke's Hospital, especially considering that a clergyman of a sister church was in great danger of dying. [The proper remedy for such an outrageous ambulance service is to place the entire ambulance system under the charge of the police, who should be empowered to compel all ambulances of so-called "private" hospitals to do such work as the police may direct.]

Reviews and Notices of Books.

A Contribution to the Pathology of the Vermiform Appendix. By T. N. Kelynack, M.D., Pathologist to the Manchester Royal Infirmary, etc. 8vo, pp. 222. London: H. K. Lewis. 1893.

This volume presents the main results of an extended investigation into a number of points connected with the pathology of the cæcal appendage. These comprise accounts of the anatomical character of the organ, its anomalies of position, and the pathological conditions as bearing upon symptoms, diagnosis, and treatment. The author has collected a large number of statistical data to prove many important points bearing upon the distinction between operative and non-operative cases, and in this way has given a decidedly practical turn to the purpose of the book which will be duly appreciated by the surgeon. His conclusions, based on pathological conditions, are not at variance with the present accepted views of operators. While laying proper stress upon the fact that many cases can recover without operation, all doubts are dispelled in those cases in which there are evidences of acute perforation, gangrene of appendix, or circumscribed abscess, and in which surgical interference is necessary to avert death. The bibliographical index is the most complete of its kind that has yet been published.

An Account of Bellevue Hospital, with a Catalogue of the Medical and Surgical Staff, from 1736 to 1894. Edited by Robert J. Carlisle, M.D. Published by the Society of the Alumni of Bellevue Hospital. 8vo, pp. 376. New York. 1893.

With the design originally of making a complete catalogue of the consulting, visiting, and resident staffs of Bellevue Hospital, we have in the present handsome volume an elaboration of the same in the appearance of a well-written and intensely interesting history of the hospital itself, with admirable portraits of several deceased members of the consulting staff. The portraits of Mott, Wood, Clark, Barker, Van Buren, Parker, Flint, Taylor, Hamilton, McCready, Crane, Sands, and Dalton speak again to the hundreds of alumni who may wish to revive the pleasant associations within the wards of the grand old hospital. The history thus presented to the ex-interne is one of the reminders of the times gone by which he will fain cherish in connection with those earlier precepts and examples which have made his subsequent successes possible. Bellevue has always been justly proud of her record, her graduates number more subsequently distinguished men than any other similar institution in the land. The editor, with a painstaking endeavor to make the book worthy of its name, has succeeded in infusing into its make-up an amount of purely literary merit which calls for hearty congratulations. The account of the founding of the hospital, dating back since 1736, is full of historical facts systematically arranged and interestingly told. The same may be said of the accounts of the different members of the staff, which in themselves constitute a study of successful work in this and other parts of the country worthy of careful contemplation.

The work is the best of its kind we have seen, will be invaluable to the alumni of Bellevue Hospital, and a notable addition to the medical history of New York.

Bryce's Pocket Practice. A Complete and Condensed Work on the Practice of Medicine for Physicians and Students. By Clarence A. Bryce, M.D., author of "Bryce's Visiting List," "Physician's Companion," etc. Richmond, Va.: The Southern Clinic. 1892.

This coat-pocket volume, prepared by the editor of the Southern Clinic, is intended to meet the wants of the "rank and file" of the profession. The author believes it absurd to claim that the majority of diseases are induced by the action of micro-organisms. Erysipelas is classified as one of the eruptive diseases, and its contagiousness is doubted. Painting iodine or nitrate of silver upon the skin to check the advance is considered worthy of trial, while scarification, pressure with adhesive strips, and the more modern local dressings are not mentioned. Under Asiatic cholera, the author appears to make an exception to his general disbelief in micro-organisms, for we find it stated that "this is a disease due to some specific germ, and seems to be carried rapidly over vast areas in the atmosphere." This and other statements are so at variance with accepted teachings, that we could not recommend the book to students or, for that matter, to practitioners, unless to be read in connection and comparison with larger works.

Transactions of American Orthopedic Association. Sixth Session, held in New York. Vol. V., 8vo, pp. 282. Philadelphia, 1893.

This volume contains interesting papers on hip disease, caries of cervical vertebræ, but notably on the treatment of club-foot, supplemented, in the discussion of the latter subject, with some admirably practical remarks from the veteran orthopedist, Dr. L. A. Sayre, of this city.

Diseases of the Skin. A Manual for Students and Practitioners. By Charles C. Ransom, M.D., Assistant Dermatologist, Vanderbilt Clinic, New York. Philadelphia: Lea Brothers & Co.

Here we have another of those attractive looking green-covered little volumes of the Students' Quiz series, edited by Dr. Gallaudet. Like its fellows, it is made up of a succession of questions and answers. Not always the kind of question you would expect a quiz master to propound, but still one giving an opportunity for instructive information under the guise of an answer. These answers, too, are sometimes quite lengthy, and embrace the whole subject of etiology, symptomatology, and treatment of the disease under discussion.

The illustrations are chosen for the most part from familiar text-book and periodical plates, and preponderate rather with exaggerated and rare examples of disease or malformation. If it were possible, it would be much better to offer the student good pictures of the every-day eruptive appearances. The student who possesses this quiz book, or any book on the subject, must remember that to learn dermatology either the eruptions themselves or accurate reproductions must be seen and studied. It cannot be learned by quizzing.

The author has accomplished a not most-pleasing task in a creditable manner, and the subject matter will be found up to date, and conforming to the teaching of leading writers.

Brain Surgery. By M. Allen Starr, M.D., Ph.D., Professor of Diseases of the Mind and Nervous System, College of Physicians and Surgeons, New York, etc. 8vo, pp. 295. New York: William Wood & Co. 1893.

This book is a timely one from an authoritative source, and will be eagerly perused by everyone interested in the study of brain lesions and their proper diagnosis and localization for operative purposes. The talented and painstaking author has collected an amount of material which in itself would be of the greatest value independent of the careful deductions which he has offered as the result of an exhaustive study of his subject. The illustrations are admirably executed and are in great variety, showing the well-recognized areas of cerebral localizations, methods of measurement, and localization of the same, with all the necessary details of operative technique. The author, although enthusiastic in the treatment of the subject and naturally optimistic in reference to many points of diagnosis and treatment which are still *sub judice*, is very candid in his recommendations and fair in his conclusions. After a careful study of the chapter on epilepsy in its relation to trephining, we are prepared for the explanation of the numerous cases of failure after operation in the complex character of lesions, which

oftentimes makes the removal of the entire area of diseased conditions impossible, notably the resulting and progressive inflammatory changes after the original injury. It would also be gratifying to learn of fewer failures when the removal of localized tumors was attempted, but the successes have, however, been sufficiently numerous to afford every encouragement for future experience and research. At present we are forced to admit that the diagnosis cannot always be surely made, and that the most careful study of clinical history, constitutional tendencies, and localizing phenomena is necessary in every case, even after a supposed syphilitic element is eliminated by a three months' trial of mercury and the iodides. The author very properly lays great stress on the two essential preliminaries to any operation upon the brain, viz., the diagnosis of the nature of the disease which is present, and of its precise situation. Between these two possibilities there is an amount of accurate knowledge, sound reasoning, and familiarity with the recognized pathological probabilities, which call for sound medical, as well as surgical, knowledge. Altogether, the work is of a character which we might expect from the well earned reputation of the author in his chosen branch, and as such is a most valuable contribution to the study of a new departure in surgery which has achieved triumphs in the past and promises great things for the future. The chapter on trephining is, from its purely practical side, a leading feature of the work, and cannot in the space allotted it be improved in completeness of necessary detail.

Transactions of the Southern Surgical and Gynecological Association. Vol. V. Fifth session, Louisville, Ky. Published by Association. 8vo, pp. 434. 1893.

This progressive Association has presented its usual interesting yearly volume pertaining to the two branches to which it devotes its energies. There is a distinct effort to make the papers of value to the general practitioner. The majority, as might be expected, bear upon gynecology and abdominal surgery, although there is one paper on brain surgery and another on hare-lip, showing bold strokes in an upward direction. To such as are interested in gynecology, the work will be specially valuable.

The Pharmacopœia for 1890.

This work, which has just been placed upon the market, becomes official on January 1, 1894. It contains the usual variety of information, historical, chemical, and pharmaceutical, which we are accustomed to find in such a volume. To the practising physician the principal interest centres around the changes which have been made since the publication of the last decennial revision in 1883. Eighty-eight new titles have been added and ninety dismissed. Among the more notable additions may be named: acetanilid, citrate of caffein, hydrochlorate of cocaine, convallaria, eucalyptol, glycerites of carbolic acid and boro glycerine, hydrogen dioxide, hydrobromate of hyoscyamine, menthol, methyl salicylate (artificial or synthetic oil of wintergreen), naphthaline and naphthol, pancreatin, paraldehyde, salol, sulphate of sparteine, the strontium salts (iodide, bromide, and lactate), strophanthus, terebene, terpin hydrate, and viburnum opulus. We think many will feel surprised that cascara sagrada has been supposedly omitted, but they will find this useful remedy under the heading of Rhamnus Purshiana.

Among the articles dismissed are, first of all, the entire class of abstracts which have proven a failure, principally because the great number of pilules and triturates upon the market have rendered them useless. Several little-used preparations of various drugs and salts are no longer included. Ignatia charta, cantharidis, and juniperus were, but are not. Also our venerable friend, azedarach, has joined the great majority.

The list of changes of official Latin and English titles, especially the latter, is somewhat lengthy. Acetate of lead becomes lead acetate, etc. The spelling of certain words is also changed, *e.g.*, creasote to creosote, opium denarcotisatum becomes opium deodoratum.

The Committee on Revision have introduced the metric system throughout the volume. The old spelling of salts (bromide instead of bromid, etc.) is adhered to. Emulsum replaces mistura in the case of several liquid preparations (ammoniæ, almond, asafœtida, and chloroform).

The fluid preparations of opium remain as before of ten per cent. strength, with the exception of paregoric (4 grammes per 1,000 c.c.). By the new method of assaying, the stronger preparations are required to yield 1.3 per cent. to 1.5 per cent. of crystallized morphine.

All compounds are very properly excluded from the Pharmacopœia which are protected by proprietary rights, or which can be manufactured only by a patented process.

The value of an intimate knowledge of the Pharmacopœia goes without saying, but if the truth must be told, we believe that physicians generally are very neglectful on this point. The many mistakes made in prescribing incompatibles would mostly be avoided if the Pharmacopœia was frequently consulted. Though it is in one sense a technical book, yet anyone of average intelligence about matters medical can understand it. No intelligent physician in general practice can afford to be without a copy. The new edition, in point of manufacture, is quite inferior to the sixth revision, published by Messrs. William Wood & Co.

The Treatment of Constitutional Syphilis. By Oswald Ziemsser, M.D., Wiesbaden. Pp. 70. London: H. K. Lewis. 1893.

The author, living at a well known German health-resort, has had an extensive practice in treating all forms of syphilis. He believes that general curative treatment should be commenced as soon as possible after infection. He believes that the notion of local preventive treatment is based on fallacious premises. The bulk of the work is given up to a careful description of the various methods of administering mercury and iodides.

Cholera. Its Causes, Symptoms, Pathology, and Treatment. By Roberts Bartholow, M.D. Pp. 132. Philadelphia: Lea Brothers & Co. 1893.

In this addition to the literature of cholera the author traverses the usual ground, and incorporates his personal experience in two epidemics of the disease. He discusses all the modern plans of treatment, and believes that our therapeutical measures are attended with a constantly increasing improvement in the proportion of cures. On the whole, we believe that Dr. Bartholow's book is the most satisfactory of all the host of short works on cholera which have appeared in the last two years.

The Law of Cremation. By Aubrey Richardson. Pp. 187. London: Reeves and Turner. 1893.

The author of this work, a son of Sir Benjamin Ward Richardson, has collected from the legal literature of various countries much valuable information on the question as to whether a person can determine for himself as to the mode of disposal of his remains after death, or whether such disposal is entirely in the hands of his executors. He outlines the laws relating to cremation in ancient and modern times, and gives the rules and regulations of various cremation societies in all parts of the world. Himself a lawyer, his pages bear the imprint of extensive research and cautious observation. We believe that Mr. Richardson's book is a valuable contribution to the literature of a matter of absorbing interest.

On Snake Poison: its Action and its Antidote. By A. Mueller, M.D. 8vo, pp. 85. Sydney L. Bruck. 1893.

This work sets forth the advantages of the treatment by hypodermatic injections of strychnine, which the writer claims to have discovered a few years ago. His pages include a historical review, careful inquiry into the effects of the virus on different bodily tissues, and then

elaborates the special antidote treatment indicated. A chapter of clinical cases is added, together with an analysis of the causes of failure in certain fatal cases. The tone of the writer is at times polemical, but he makes a good presentation of the subject.

Cholera for Lay Readers. By Walter Vought, Ph.B., M.D., Physician in charge of the Fire Island Quarantine Station, Port of New York, etc. Pp. 105. Philadelphia: F. A. Davis. 1893.

Nothing new to the physician can be expected in a manual of this kind, which traverses only the conventional ground indicated by its title. We regard as its most important chapter the one which proves that, and shows how cholera may be prevented. Full directions for disinfection, etc., are given.

The Era Key to the United States Pharmacopœia for 1890. Detroit: D. O. Haynes & Co. 1893.

This is a small pocket manual containing an alphabetical list of the preparations of the new Pharmacopœia, with doses; convenient for reference.

Hernia: its Palliative and Radical Treatment in Adults, Children, and Infants. By Thomas H. Manley, M.D., New York, visiting Surgeon to Harlem Hospital, etc. 8vo, pp. 227. Philadelphia: The Medical Press Co. 1893.

The revival in recent years of the study of hernia has led to a perfect deluge of literature on the subject, with the result that we have had many indifferent and a few good contributions to our previous knowledge. The author finds in his dissatisfaction with existing treatises his justification for the preparation of still another. The work goes over the whole field with considerable minuteness, and is illustrated with numerous woodcuts, many of which are original, having been drawn from the writer's preparations.

The absence of a table of contents renders it somewhat difficult to give an outline of the author's views, and the index is so incomplete as to be practically worthless.

Physician's Chart-Book. New York: Bailey and Fairchild. 1893.

This is a pocket edition with the usual chart-rulings for pulse, temperature, etc. It has no practical differences from dozens of its class.

Minor Surgery and Bandaging, including the Treatment of Fractures and Dislocations, Tracheotomy, Intubation, Ligation of Arteries, and Amputations. By Henry R. Wharton, M.D., Demonstrator of Surgery, University of Pennsylvania, etc. Second edition. 8vo, pp. 529. Philadelphia: Lea Brothers & Co. 1893.

This concise work covers such a large portion of the field of general practical surgery that its main title is somewhat of a misnomer. We are not disposed, however, to criticise it on this account. Rather is the author to be congratulated that he has carried the art of condensation to such a degree of perfection. The section on bandaging is exceptionally well written, and the illustrations are so clear as to be almost as good as the living model. Of course little that is intrinsically new can be looked for in such a work.

Heath's Practical Anatomy. Edited by William Anderson, F.R.C.S., etc. Eighth edition, with 329 Engravings on Wood. 8vo, pp. 744. Philadelphia: P. Blakiston, Son & Co. 1893.

This work was written primarily for English students, and has in the present edition been subjected to an extensive revision in order to bring it to a level with current teaching with the present requirements of the London Examination Boards. It can never supersede the works of Gray and Quain, in this country at least, though it has good features peculiar to itself. For a review of the subject just previous to examination or for consultation by the operating surgeon, it is of especial value, as all irrelevant matter is excluded and one comes at once down to solid meat. Along the lines of regional anatomy it is worthy of special commendation.

Lectures and Essays on Fevers and Diphtheria, 1849 to 1879. By Sir William Jenner, Bart., G.C.B. 8vo, pp. 581. New York: Macmillan & Co. 1893.

These essays have all been published in various journals during the three decades mentioned. Owing to the vast strides which have been made in the study of these diseases, the volume has perhaps more of a historical than a practical value. Nevertheless, we must always remember that our knowledge of the present is largely a sifting of the work of our predecessors, and the high standing of the distinguished author alone would justify the preservation of his writings in the present form. It seems like going back to old times to read a paper on the "Identity or Non-identity of Typhus and Typhoid Fevers," yet this was one of the burning questions of the pathology of forty years ago.

It is good for the student of the present day to read the essays of the preceding generation. We pore so constantly now over the revelations of the test tube and microscope that we are in danger of forgetting that there is a physiological as well as a physical factor in diagnosis. In the matter of accurate description and grouping of symptoms, it is an open question as to how much we have improved upon the systematic methods of our fathers, and he who would pose as an authoritative writer of the present day must frequently go back to such writings as those which Sir William Jenner has collected in the present volume.

The author's breadth of view and clear diction alike make his writings a delight, and we are sure that they will ever hold their present position as an English medical classic.

Electricity in Diseases of Women and Obstetrics. By Franklin H. Martin, M.D. With Illustrations. Chicago: The W. T. Keener Company. 1893.

The author of the second edition of this treatise compliments himself on the hearty reception accorded to his work by the profession. Indeed even a captious critic will find little to merit anything but approval in this elementary work, which is evidently intended more as a guide for students than a reference book for practitioners. As for the so-called electro gynecologists, every one of them has his own peculiar ideas, which he ventilates sooner or later in book form.

Stricture of the Urethra. By G. Frank Lydston, M.D. Chicago: The W. T. Keener Company. 1893.

As compared with similar works on this subject, Dr. Lydston's book has the merit of leaving no doubt in the reader's mind what particular method of treatment is considered advisable by the author. The illustrations are mainly reproductions of well known originals. Lydston's views are those of a modern antiseptic surgeon, and do not differ materially from those now entertained by leading genito-urinary specialists.

Sciatica. A Record of Clinical Observations on the Causes, Nature, and Treatment of Sixty eight Cases. By A. Symons Eccles, M.B. Aberd., Member Royal College of Surgeons, England, etc. Pp. viii.–88. London: Macmillan & Co. 1893.

The generally accepted views touching the origin, symptoms, and treatment of sciatica, are lucidly presented in this brief record of personal observation. The author does not aim to furnish an elaborate monograph on the subject. . . . As a clinical contribution to sciatica the little book will be read with interest.

Society Reports.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, November 3, 1893.

CHARLES L. DANA, M.D., PRESIDENT, IN THE CHAIR.

DR. V. P. GIBNEY presented three patients in illustration of his paper, "A Study in Congenital Deformity."

Discussion took place later.

A Simple Method of Closing Operation Wounds by Sliding Skin Flaps.—DR. GEORGE F. SHRADY described the method. (See page 717.)

DR. ROBERT ABBE thought the operation described by Dr. Shrady filled exactly a want in certain cases. As a rule, however, he had found Thiersch's skin-grafting give satisfaction. The chief need was to avoid tension and irritation in the wound.

DR. J. D. BRYANT said he had usually resorted to Thiersch's skin-grafting, but he recalled one case in which it was necessary to make a Y-shaped incision below the breast and slide the flap upward to close the large operation wound. The method, which was an old one, served the purpose very well in that case.

DR. SHRADY said, in connection with Dr. Abbe's remarks, that the method which he had described prevented the formation of cicatricial tissue, and avoided the necessity for transference of flaps. He had tried Thiersch's method frequently in covering up granulation wounds after amputation of the breast, and so on, but had found the resulting skin rather thin, leaving, in many instances, a very depressed scar with deficient tissue substance. At any rate, he thought it was preferable to have a thick integument over the wound from which the cancerous mass had been removed. The method described was applicable, of course, only to extreme cases, where a large portion of integument had been sacrificed.

The incision to which Dr. Bryant had referred was an excellent one, and he had himself used it occasionally with satisfactory result.

Obstructive Carcinoma of the Duodenal Papilla: Primary Cholecystotomy, Pancreotomy; Secondary Cholecystenterostomy by Murphy's Button.—DR. R. F. WEIR presented specimens and related the case, which is published at length on page 801 of this issue.

In connection with this case Dr. Weir referred to another, of tumor of the pancreas, in a woman twenty-nine years of age, who entered the hospital with the history that once before the tumor had come and disappeared. After etherization Dr. Weir found the belly was much more flaccid than it had been the night before, and on making an exploratory incision the tumor had entirely disappeared. It had been the size of two fists, and without special hardness. It had not returned since, and the patient had remained well. The only inference to be drawn was that there had been pancreatic calculus which became dislodged. It should be said that before she came to the city a country physician had punctured the tumor, withdrawn fluid, and found pancreatic reaction. It might also be remarked that an English observer, named Walker, had said the dark-brown color of the stools was due to the admixture of pancreatic secretion. In this woman's case the stools had all the time been of dark brown color.

DR. W. GILMAN THOMPSON said he had been struck with the great digestive activity of the pancreatic juice in Dr. Weir's first case. The man's nutrition had remained surprisingly good the few days after the operation, considering the loss of so large a quantity of pancreatic secretion.

THE PRESIDENT inquired whether there had been diabetes, and Dr. Weir replied that the urine contained some casts, but no sugar.

DR. PEABODY said the question had arisen in his mind, since having this case transferred from the medical to the surgical ward, where it was operated upon by Dr. Weir, if it would not be better, where obstruction of both glands was present, to examine the duodenum at once through an incision.

DR. WEIR said that question had also come to his mind, but the temptation was, on finding the obstruction and swelling, to cut into it; and had the patient's condition admitted a prolongation of the first operation, he would have resorted to it. He thought that in a similar case, and in a good many cases of calculous obstruction of the common duct, where we either failed to recognize the obstructing cause or were unable because of adhesions to dislodge it, it would be better to open the duodenum and attack the obstacle from that direction. No great damage would follow, unless the drainage-tube or tampon also occluded the duodenum, as the opening in the intestine would soon close.

DR. ABBE doubted whether attacking the papilla which obstructed the opening of the pancreatic duct from within the duodenum would be of much permanent value, not even if the opening were split up a little way, and therefore it would be better, he thought, to resort to the use of Murphy's button at once. Moreover, the handling of the parts which would be necessitated by opening the duodenum would cause considerable shock, as he had had occasion to know from experience with two cases. Having decided on establishing anastomosis, the question would arise, in case of biliary obstruction, what portion of the gut should be selected. Dr. Abbe thought there was no objection to making the connection with the colon instead of the small intestine, as experience had shown that no injury to the health resulted from having the bile empty into the duodenum, and it was easier to make the connection with the larger gut. If the small intestine were used, a kink would form which he thought would be more likely to result in fæces entering the gall bladder than in the other case. Herd had reported a case of anastomosis between the gall-bladder and ileum, which was followed by regurgitation into the gall-bladder and death.

DR. WEIR thought, from theoretical considerations, that there would be more danger of regurgitation of gases and infecting germs from the colon than from the upper intestine.

DR. ANDREW H. SMITH inquired whether the amount of the pancreatic secretion had been estimated.

DR. WEIR said that in his case some of the fluid escaped alongside the tube, so that the daily quantity could not be estimated with any approach to accuracy. It was estimated that from six to eight ounces escaped daily. Murchison placed it at forty ounces.

DR. THOMPSON said the pancreatic fluid, when collected through a tube, became much increased after a day or two, but less active. That present in Dr. Weir's case was much more vigorous than any which he had ever collected in cases of pancreatic cyst.

DR. WILLIAM M. POLK had had a case which confirmed Dr. Thompson's statement that the pancreatic fluid became greater in quantity but less active some time after the fistula had been established. The case to which he referred was one of pancreatic cyst, the size of an adult's cranium, which he tapped about three years ago, and the man's condition became so comfortable and his nutrition so satisfactory, that he refused to have the tumor removed subsequently. He was still living, the fistulous opening still persisted and discharged pancreatic fluid.

Dr. Polk thought the suggestion made by Dr. Peabody, to open at once into the duodenum in cases of biliary obstruction, an important one. It enabled one to explore the pancreatic duct as well as the biliary, and, according to his experience with one case, was a perfectly harmless procedure. The case occurred about three years ago, and in many regards was like the one related by Dr. Weir. He opened the gall-bladder and found about the same condition; met with the same failure on attempting to sound the ducts; then made a free incision into the duodenum, examined carefully the orifice of the common duct, and finding the stone farther from the intestine than he had supposed, so far that he could not remove it from that direction, he sewed up the duodenal wound, broke up

the stone, and succeeded in working it back and out at the gall-bladder, after the manner suggested by Mr. Tait. The gall-bladder was left open, no attempt being made to establish anastomosis with the intestine. He had expected to operate again, but the woman did so well, the jaundice disappeared, the discharge of bile through the opening soon ceased, the opening closed of its own accord, so that nothing further was done.

Dr. W. T. Bull would not regard the suggestion of exploring the duodenum, suggested by Dr. Weir, as quite so trivial a matter as it seemed Dr. Polk did. He thought opening the duodenum was rather a serious complication of any abdominal operation, basing his opinion upon personal experience and upon the physiology of the parts. Once, in trying to extract a gall stone which he thought was in the cystic duct, it proved that there was such close adhesion to the gut that he tore into the duodenum, and although the tear was not more than three quarters of an inch in length and was carefully closed, yet union failed, and there was so copious a discharge from the fistulous opening that the patient came near starving. He thought it was an accepted surgical rule that the duodenum should not be opened if it could be avoided, lest there should be failure of nutrition. He did not suppose that in a case like the one reported by Dr. Weir, the surgeon could hope to extirpate the malignant disease. The case had been of interest to him in the facility with which, it was said, Murphy's button could be used. It did not seem to him that the establishing of an artificial opening between the gall-bladder and intestine was likely to prove of any use, except where there was unquestioned evidence that the calculus which could not be removed was the sole cause of obstruction. If there were carcinoma of the cystic or bile duct, he would prefer to leave the patient to nature rather than assume the risk of making anastomosis. Little benefit could be expected to follow the operation, even should it not endanger life.

Dr. Weir thought Dr. Bull must have misunderstood him. When he referred to opening the duodenum, it was not in recognized carcinomatous trouble, but for exploratory purposes, especially where it was probable that gall-stones existed which could be best attacked from within the intestine. He knew of four or five cases in which the duodenum had been opened, without a single death. It would appear, therefore, that the objection which had been offered was rather theoretical.

Dr. Bull remarked that statistics had shown that, in fully one half the cases of jaundice from obstruction by gall stones, there was complicating malignant disease, and he therefore thought that in doubtful cases surgical operations should be of a conservative character.

Tongue Clamp.—Dr. Weir presented for inspection a novel tongue forceps for use in the accidents of anæsthesia. It was devised by Dr. Berger, of Paris. It is intended to replace the more clumsy and less rapid method of making traction on the tongue by means of a loop of silk passed through its tip by means of a curved needle.

A Study in Congenital Deformity, Clinically Illustrated.—Dr. Virgil P. Gibney then presented an abstract of his paper upon this subject.

Dr. Polk would be much interested to know what might be the etiology in the class of cases presented by Dr. Gibney.

Dr. Gibney said he had no knowledge of the cause. He had been able to question the mother in the case of the second child, and she knew of nothing unusual during the course of her pregnancy to account for the deformity. In cases of club-foot the explanation which had been offered was that the foot remained in the position which it assumed in early fœtal life. In the cases just presented he thought there must be some defect in the nervous system. Replying to an interrogatory by the President, whether there were other similar cases on record, he said he knew of none.

The President thought Dr. Gibney's cases fell under the department of teratology, and not of neurology; that they were not due to any defect of the nervous system. As had been said, the patients were bright mentally, whereas in congenital neurotic or nervous troubles the condition was nearly always progressive; the subjects become worse.

Epithelioma of the Breast.—Dr. William T. Bull presented specimens from a case with history.

Carcinoma of the Vermiform Appendix.—Dr. Weir presented a microscopical slide, showing carcinoma of the vermiform appendix, the organ having been removed during the quiescent stage after the twelfth attack of recurrent appendicitis. No tumor had been felt, nor to the naked eye was there anything pointing to malignant disease. The complication is an unusual one, for, so far, he had not been able to find record of a similar case.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 25, 1893.

H. P. Loomis, M.D., President, in the Chair.

Duodenal Ulcer with Abscess.—Dr. George P. Biggs presented a specimen of duodenal ulcer with abcess, found at autopsy on a female, twenty-seven years of age, who died of acute general peritonitis and intra-peritoneal abscess, the result of septic endometritis. Three weeks before admission to the New York Hospital she had a miscarriage during which she lost considerable blood. This was followed by profuse vaginal discharge, irregular chills, fever, and severe abdominal pain with tenderness and distention, lasting for one week. The discharge then ceased almost entirely, but she developed, in addition to the previous symptoms, sweating, cough, dyspnœa, vomiting, and diarrhœa.

On admission to the hospital examination showed a distended tympanitic abdomen, not very tender, owing to the almost moribund condition of the patient. The cervix was lacerated, but the internal os was closed. The uterus seemed fixed. Subcrepitant râles were heard all over the chest. She lived but four days, during which time her temperature varied from 100 to 101.8° F., and the pulse from 120 to 150.

At autopsy both large and small intestines were found enormously distended, and adherent to each other and the abdominal wall by recent adhesions. In the left inguinal region, and extending to the median line in the hypogastric region, there was found a cavity about the size of an orange, filled with thin, fecal pus. The walls of this space were formed by the left horn of the uterus, left broad ligament, small and large intestines, and peritoneum of anterior abdominal wall, which were united together by fairly firm adhesions. This space communicated by two openings, each about one by one-half centimetre, with the sigmoid flexure, by one similar opening with the small intestine, and also by a large opening with an abscess cavity in the cul de sac of Douglas. The uterus was slightly enlarged and the endometrium at the placental site covered with a diphtheritic membrane. The Fallopian tubes were moderately enlarged, but contained only a very small amount of pus.

In the posterior wall of the duodenum, just beyond the pylorus, was a circular ulcer, 1 ctm. in diameter, with smooth, rounded, firm border, communicating with an irregular, tortuous sinus, 5 ctm. in length and 1 ctm. in diameter, running along the upper border of the pancreas 6 ctm., and terminating in an abscess cavity about 5 ctm. in diameter, the walls of which were formed by the diaphragm above and behind, the upper border of the pancreas below, the posterior wall of the stomach an-

teriorly, and the inner surface of the spleen externally. There was no communication between this abscess and the general peritoneal cavity, though the adhesions of coils of intestine about it were numerous and suggested possible extension of inflammation through the wall. Other lesions of importance were broncho-pneumonia, pulmonary œdema, and chronic diffuse nephritis.

Dr. Biggs said he considered the peritonitis and intraperitoneal abscess to be secondary to septic endometritis and salpingitis. Primary ulceration of the intestine could be excluded, as all the perforations, with the exception of the one in the duodenum, were very clearly from without inward. Entire absence of lesions of the mucous membrane, except at points of perforation, all three of which were into a single cavity, would also be against ulceration beginning in the mucous membrane. The softened semi-necrotic condition of the intestine surrounding the abscess explains the ease with which perforation was produced into the intestine, fecal matter finding entrance into the abscess cavity by the same channels.

The abscess connected with the duodenal ulcer had produced only a slight local peritonitis, and apparently had no etiological relation to the general peritonitis or the fecal abscess. Perforations of the duodenum are usually of the anterior wall, and produce death quickly from shock or from acute general peritonitis. The firm, smooth, rounded border of the ulcer in the specimen presented would indicate comparatively long duration. It is of the so-called "simple" variety, the etiological factors concerned in their production being probably the same as those active in the production of similar gastric ulcers.

Carcinoma of the Stomach and Perforation of the Duodenum.—Dr. Biggs also presented a specimen showing carcinoma of the stomach and duodenum, with perforation of the duodenum at a point not invaded by the new growth. It was found at autopsy on an Italian woman, about fifty years of age, who died a few hours after admission to Chambers Street Hospital. The body was extremely emaciated and the abdomen distended, tense, and tympanitic. A large amount of gas escaped on opening the peritoneal cavity. There was only a slight general peritonitis, and comparatively little fluid in the peritoneal cavity.

The pyloric end of the stomach for a distance of 6 ctm. from the pyloric ring was firm and rigid, the wall being 1½ ctm. in thickness, and evidently indurated throughout with tumor tissue. The internal surface was smooth, distinctly fibrous in consistence, and devoid of ulcerations. There was no obstruction at the pylorus, though it was equally invaded by the tumor tissue. The stomach was not dilated. With the exception of an area in the anterior wall, 2½ ctm. in diameter, located just beyond the pylorus, the first 6 ctm. of the duodenum presented the same appearance as the pylorus, save that the wall was only ¾ ctm. in thickness and the mucous membrane not so completely destroyed. The portion of the anterior wall not involved was almost membranous in thickness, apparently purely fibrous in structure, and in its central portion there was found an oval perforation measuring 5 × 3 mm. No adhesions had been formed to neighboring tissues. Malignancy of the growth was clearly shown by extensive invasion of the tissues behind the pylorus and duodenum, the lesser and the greater omentum, the latter being drawn up into a hard cord, parallel to and attached to the greater curvature of the stomach. Two small whitish points in the left lobe of the liver, just beneath its capsule, had the appearance of metastases.

Microscopical examination of the pylorus showed that the mucous membrane and submucous layer had been completely replaced by a thick layer of fibrous tissue containing a comparatively small number of alveoli filled with epithelial cells of small size. Distinct alveoli were more numerous in the deeper parts. Portions of the fibrous tissue were quite dense, while other portions were rich in ovoid and spindle cells. The entire thickness of the muscular wall was infiltrated with similar tumor tissue, which, however, contained less fibrous tissue. Typical alveoli, filled with epithelial cells, were comparatively few, but sufficiently so for a positive diagnosis of carcinoma. The blood supply of the tumor tissue was very scanty. The gross as well as the microscopical appearances of the inner surface of this tumor suggested an attempt on the part of nature to completely heal over the large ulcerated surface which must have existed in an earlier stage of the growth. The history of the case must have extended over a long period, but unfortunately nothing could be learned regarding it.

The two minute points in the liver had the structure of medullary carcinomata, in which the cells were rather small and the alveoli delicate.

The cause of the extreme thinness and fibrous character of the uninvolved portion of the duodenum appears to have been lack of sufficient blood supply, the circulation through the surrounding tissues being interfered with by the deposit of dense, fibrous carcinomatous tissue. The superior pyloric branch of the hepatic artery mainly supplies this area, and probably was compressed or occluded by the growth.

Lesion of the Bladder Produced by the Distoma Hæmatobium Bilharzii.—Dr. J. S. Thacher presented a portion of a human bladder, exsected a few days previously at St. Luke's Hospital, by Dr. B. F. Curtis, and sent to the laboratory for a diagnosis of the nature of the tumor which it contained. When seen after immersion in alcohol, the mucous surface appeared intensely congested, and presented low, nodular elevations. There was one particularly prominent, measuring one-half inch in diameter, and having a rough surface like that of a papilloma. Stained sections were examined with the microscope, and after the first few examinations a preliminary report was sent, stating that no neoplasm had been found—nothing but inflammatory changes. On examining sections from the above-mentioned nodule, however, unusual appearances were noticed. Papillary outgrowths were seen, covered by a thickened epithelial layer, which also subdivided them by frequent in-dippings. At these spots there were abundant leucocytes, extremely distended capillaries, and many clusters of oval bodies resembling the eggs of the distoma hæmatobium Bilharzii. These ova are from 80 to 120 μ in length, from 30 to 40 μ in width, oval, and with a sharp, short projection at the smaller end. The outline is thin, but distinct; the contents of some finely, of others coarsely, granular; in some filling the shell, in others leaving a space just inside the shell, particularly at the ends. In some the granules are evenly distributed; in others there is a distinct circle of them at the centre of the ovum. They lie sometimes just beneath the epithelium, and again 2 mm. from it.

Adjacent portions of the bladder-wall show inflammatory infiltration, not entirely uniform in distribution, marked congestion, and many tubercle-like nodules. These last are about ½ or ⅔ mm. in diameter, are surrounded by a zone of crowded leucocytes, and made up of variously shaped connective-tissue cells, with scant fibrous material, giant-cells, and a few leucocytes. The giant-cells are rather irregular in shape, with many nuclei variously disposed. There are rarely any necrotic centres to the nodules or the giant-cells. There are usually present in the nodules several irregular lines of striking refractive power, often surrounding open spaces, and supposed to be shrivelled shells of the ova. Occasionally a shell is found of the regular oval shape.

The inflammation extends hardly at all into the muscular coat. The superficial epithelium, where retained, is thickened, but is for the most part lost.

On comparing these appearances with the descriptions given by Bilharz,[1] Griesinger,[2] Zancarol,[3] Harley,[4]

Brock,[1] and others,[2] there can be little doubt that the ova are those of the distoma hæmatobium Bilharzii, or Bilharzia hæmatobia. This diagnosis having been made it was confirmed by learning that the patient had been a British soldier, and was eight years ago stationed in Cairo, and that hæmaturia had been a prominent symptom in his case for the past three years. Notwithstanding the remarkable prevalence of this parasite in various parts of Africa and the neighboring islands, it has been but rarely observed in Europe, and the speaker said he knew of no case reported in this country, though he had been informed that the eggs had been recently found in Chicago.

It is noteworthy that the bladder symptoms in this patient did not appear until five years after he left Egypt. Dr. Norman Moore reports two cases[3] observed in England, in each of which the trouble first manifested itself sixteen years after the patient left the country where he had undoubtedly been infected.

In regard to the tubercle like nodules in this specimen, it is interesting to compare the observations of Miura[4] and Laulanié,[5] who describe similar results from the presence of trematoid and nematoid eggs.

A Large Renal Calculus.—Dr. H. P. Loomis presented a calculus three inches in length by two inches in thickness, which had been removed recently by Dr. L. A. Stimson from a young man, nineteen years of age, whose symptoms of calculus dated back about three years. He gave a history of attacks of pain on exertion, of frequent micturition, and of passing dark and bloody urine. On account of his age and family history it was supposed at one time that his symptoms might possibly be due to tuberculosis, but no bacilli could be found in his urine. Repeated examinations of the urine at different times showed the presence of albumin, pus, blood, and granular and hyaline casts. At the operation the left kidney was found normal in size, and structure, yet this large stone was lying loose in the pelvis of the kidney. It was removed, and the kidney sewed up and replaced. In about ten days the patient was up and around. The outer crystalline portion of the calculus had been examined and found to consist of oxalate of lime.

The chief points of interest in the case are: 1, The size and general appearance of the calculus; 2, the age of the patient; 3, the fact that oxalate of lime calculi are much less frequent than those composed of uric acid; 4, the quick recovery of the patient; and 5, the fact that the kidney itself was not diseased.

Dr. Morris, of London, in a recent paper, reports the results of his examination of all the calculi in the Hunterian Museum—the largest collection of the kind in the world. He states that the calculi occurring in childhood consist almost always of urate of ammonia, those found in early adult life are composed almost uniformly of uric acid, while in later life oxalate of lime calculi are the most common.

The Society then went into executive session.

Prorotomy.—When it is necessary to enlarge the meatus in stricture operations it is best to keep the cut surfaces separated by a small pledget of gauze until complete cicatrization takes place. The patient can change them at each urination, and thus avoid the disagreeable hemorrhage and pain which accompanies the subsequent passage of sounds, as it is almost impossible to thoroughly cocainize this part by injecting the solution.

Sounds or other instruments should not be put into the jar of vaseline, and it is preferable to keep the lubricant in compressible tubes, which insures against subsequent infection.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, November 20, 1893.

Samuel B. W. McLeod, M.D., President, in the Chair.

Operation for Varicocele.—Dr. Samuel E. Milliken presented three men on whom he had operated for varicocele, removing the enlarged veins, except a few to nourish the testicle; in one the operation having been performed a week ago, in another one year ago, in the third, three years ago. There had been no tendency to recurrence. He had not found any necessity for excising the lower end of the scrotum, as had been advocated by some. All the symptoms had been relieved. The patient was detained from work only a week or ten days, but it required six to eight weeks for inflammatory trouble to subside after the operation.

Hammock for Applying Plaster-of-Paris Jacket.—Dr. Milliken also exhibited a portable apparatus for applying plaster-of-Paris jacket in the horizontal position in the Pott's disease of childhood. It was a kind of hammock, consisting of canvas stretched over two rollers, the latter supported by legs like those of a folding-table, a handle with ratchet-wheel turning one roller, and thus tightening the canvas to any required degree. The objection to the suspension apparatus had been in his hands the fright which it caused the little patients, and sometimes almost fatal syncope.

Prefers Suspension.—Dr. Reginald H. Sayre thought the apparatus well arranged as a hammock for applying plaster-of Paris jacket, but in his experience it was only in exceptional instances that the horizontal posture should be chosen: as in cases of long confinement to bed with abscess, or paraplegia with weakened heart-action. Wherever possible, it was desirable to apply the jacket while the patient was suspended, so as best to relieve the vertebræ of pressure, especially to take the superincumbent weight off the diseased portion. Regarding the outcry which children made during suspension, he had not often met with it. On the contrary, they were usually well pleased with it because of the relief from pain which it gave. The fact had been pointed out by his father some years ago, in his reply to Mr. Davy, when this gentleman first advocated the hammock. The great point in the treatment of Pott's disease of the spine was not fixation, but extension, and this could be best obtained by applying the jacket while the child was suspended. The jurymast was of further aid in some cases.

Dr. Judson thought that the apparatus shown was a great improvement over Mr. Davy's hammock. He stated that he had had almost no experience with plaster-of-Paris applied in either the recumbent or suspended position. He preferred antero-pressure applied by the use of a brace made of soft steel, which permitted changes and ready adjustments. He would apply pressure from behind forward at the level of the projection, limiting the degree of pressure only by the tolerance of the skin, and from before backward at the pelvis and the shoulders. He advocated the removal of the superincumbent weight from the diseased parts, and thought that was best accomplished by antero-posterior pressure or support, which transfers the injurious weight from the diseased vertebral bodies to the articulating processes, which are sound and well able to bear the extra pressure.

Dr. von Donhoff had been impressed with the danger of applying plaster jackets during suspension in a case of fracture of the spine, his patient passing almost into fatal syncope. He thought all the extension which was desirable could be obtained by antero-posterior pressure, applying the jacket while the patient lay on the hammock, back up. The plaster jacket should serve only as a mould from which to make one of manilla paper, in order that the patient might not be burdened with a great weight. He had never seen a jurymast do any good, unless the disease were high up. Apparatus, as

applied in many cases of Pott's disease, reminded him of a man trying to lift himself out of a mud-hole by pulling on his shirt collar.

Dr. Hoag had occasionally found trouble with adults during suspension, but not with children; at least, not longer than the first minute or two. He thought it was quite generally admitted that there was no cure for Pott's disease, except extension. Therefore, the jacket should be applied during suspension, and paper afterward take the place of plaster.

Dr. Milliken thought the plaster-of Paris jacket was a very cumbersome affair at best, and there were several other kinds of apparatus which were superior to it. All that we could expect in the line of extension was sufficient antero-posterior extension to prevent any further deformity. The plaster-of-Paris jacket was simply an immobilizing apparatus. In hospital practice it took so long to overcome fright and struggling during suspension, that this method had to be given up for the hammock.

The Treatment of Uterine Fibroids.—Dr. Augustus H. Goelet read the paper. According to his view, operative interference in interstitial and subperitoneal fibroids was limited to a narrow field. Nearly all cases were amenable to other treatment, especially electrical. He would try electricity in all cases, including those of small fibroids giving no symptoms, for galvanism often diminished the size of the tumor, and tended to prevent the development of symptoms in the future. Regarding the method of applying the current, some opposed puncture of the tumor, but Dr. Goelet regarded this as a safe and the most effectual method. He preferred vaginal puncture into the tumor, observing, of course, strict antisepsis. It had been objected that this treatment placed the patient in an unfavorable condition for operative interference, should this prove necessary. Dr. Goelet said just the contrary was the truth; that by checking hemorrhage, etc., the current put the patient in better condition to withstand an operation. If hemorrhage were excessive, curettement might precede electrical treatment. If hemorrhage followed electricity, it was due to the fact that the pole had not reached the entire cavity. The copper electrode was best for controlling hemorrhage. Where there was failure by this method, ligation of the uterine arteries might succeed. Removal of the tumor and uterus was called for in some cases. Extirpation of the ovaries had been abandoned by most operators, and in the opinion of the author should be practised only where these organs were themselves diseased. He had no faith in ergot or hydrastis. He did not discuss methods of hysterectomy.

Dr. George T. Harrison congratulated the author on his successful treatment of uterine fibroids without operation. Uterine puncture by one electrode might be safe in the hands of one so skilful as Dr. Goelet, but he thought it would be dangerous practice among the general profession. He was surprised to learn that treatment by removal of the uterine appendages had been abandoned. He knew that Dr. Lusk still had confidence in it.

Dr. Nathan G. Bozeman thought that subperitoneal fibroids, especially if they had a pedicle and were large, ought always to be operated upon. By pressure, they produced renal, vesical, and other symptoms.

Dr. J. Mount Bleyer said his practice had been devoted chiefly to the air-passages, but he might express the opinion that most failures in the treatment of uterine fibroids by electricity were due to studying the subject backward instead of forward. The tumor was not punctured deeply enough, or at a sufficient number of places.

Dr. Boardman Reed, of Atlantic City, said he had seen enough of Dr. Goelet's work to believe in his success with the electrical treatment. He had himself been able to control hemorrhage in a case of bleeding sarcoma by the use of galvanism.

Resolutions were adopted relating to the death of Dr. W. T. White.

Surgical Suggestions.

Superficial Excoriations produced by braces or adhesive plaster are readily healed by the free application of the sub-iodide of bismuth. It is a fine red powder with unusual absorbent and antiseptic powers.

Acute Hydrocele in Children, if tapped with a small trocar and cannula, can almost invariably be cured, if the sac is irritated, after the evacuation, with the blunt end of the cannula.

Potassium Permanganate solution (1 to 1000) is an excellent local antiseptic for the urinary tract. One of the advantages it has over other agents is that so long as pus or other excrementitious matter is present the fluid will be changed in color from the de-oxidation. For acute gonorrhœa it is particularly applicable, and in the preparation of cases for operation.

How to Find the Upper Extremities of the Divided Tendons in Cases of Division of the Flexor Tendons of the Fingers.—Félizet, of Paris, France, says: "I have observed a tolerably large number of cases of division of the flexor tendons of the fingers in which I had recourse with success to a very simple procedure in order to facilitate the search for the upper extremities of the divided tendons. My observations do not apply to wounds of the tendons of the thumb but only to those involving the flexor tendons of the four fingers, whether in the hand or at the wrist. The method of procedure I employ to trace the upper end of the divided tendon is based on the anatomical disposition of the fine fibrous bands which bind the tendons together. For example, to find the upper extremity of the flexor tendon of the middle finger, the other fingers, or at any rate the ring-finger, should be fully extended, and as a result the cut end of the tendon looked for is made to emerge, being dragged upon by the fibrous bands which bind it to the other tendons. The same principle can be applied in suturing a divided tendon. The neighboring fingers, the tendons of which are still entire, being fully extended, the cut extremities of the injured tendon approach each other, and the suture is rendered more secure by the upper end being stitched to one of the adjoining tendons before the divided extremities are united."

Multiple Operations at One Sitting.—For the past two years I have frequently done several operations at one sitting. I have repeatedly repaired the cervix and perineum and curetted the cavity of the uterus before opening the abdomen for the removal of pus tubes, and afterward stitched the fundus of the uterus to the anterior abdominal wall with silkworm-gut, and have thus far seen no cause to regret doing so.—Cushing.

I Hold that to put up all injuries of the elbow at right angles is a dangerous routine practice, as is shown by the number of cases of deformity that have been recorded, and by the very grave prognosis given by all our standard text-books.—Frere.

Wry-neck.—That shortening of the structures which produce wry-neck may occur during fœtal life has been demonstrated. Congenital wry-neck is never to be charged to the fault of the accoucheur or the midwife.—Peterson.

A Mild Degree of albuminuria (or nephritis), especially if recent, is not a contra-indication to the use of chloroform. Even in the presence of advanced and extensive renal changes an anæsthetic may be employed, provided the patient or the family be advised of the additional risk.—Long.

Senile Gangrene.—So long as the gangrene be confined to one or two toes one may wait and abstain from other than general antiseptic treatment, with high position of the limb, allowing the part to be spontaneously thrown off. If the process extends, however, to the dorsum or

sole of the foot, one should amputate above the condyles of the femur. Amputation below the knee is almost always followed by gangrene of the flaps and brings the patient in danger.—Powers.

Be Prepared to go ahead the moment patient is unconscious; don't waste either the anæsthetic or the patient's forces while you are threading needles.

Find the source of hemorrhage in gunshot wounds of the abdomen before you begin sewing up the wounds in the intestines.—Dalton.

Gall-stones call for operation when they cause frequent, repeated, or long-continued trouble. Operation is required for empyema of gall bladder, and for hydrops too, if it causes much annoyance. If cystic duct is closed, the gall-bladder inflamed, or its contents much altered, a temporary biliary fistula should be made.—Czerny.

Gastrostomy.—In the treatment of impermeable cicatricial stenosis of the œsophagus, gastrostomy not only furnishes a new inlet for the introduction of food into the stomach, and thus prevents death from starvation, but it often proves a curative measure in such cases, as the gastric fistula can be utilized for another purpose—successful retrograde dilatation of the stricture—Senn.

Golden Rules.—Never tap a suspected renal tumor through the abdominal parietes, *i.e.*, through the peritoneum. Never think lightly of any ulcer of the tongue or lips of a patient beyond middle life. Never permit a healthy wet-nurse to suckle a syphilitic child, or child of syphilitic parents. Never neglect to warn your patient about his eyes in treating a "first" attack of gonorrhœa. Never forget many gleets are due to slight contractions of the canal and may be cured by a steel bougie.

Creosote Subcutaneously.—In a large number of cases antisepsis in tuberculous phthisis can be secured by slow injection of pure creosote in olive-oil, sterilized by exposure to a temperature of 110° F. Thirty grains of liquid can be introduced beneath the skin in an hour.—Gimbert.

Empyema.—In the greater number of cases the resection of a part of a rib—usually about an inch of the middle third of the sixth or seventh—is incomparably the better plan; it should not occupy more than ten minutes, the peeling off of the periosteum occupying the greater part of that time, it gives ample space for emptying and washing out the cavity, and a new lamina of bone is soon secreted by the uninjured periosteum to repair the loss. But there is one precaution; keep the finger in the opening lest the pus escape too rapidly and the patient die from syncope.—Cadogan-Masterman.

Fractures.—The immediate application of a plaster-of-Paris dressing to a recent fracture is wrong, because the healing of a fracture with deformity can be prevented only by a perfect diagnosis in which the form of the fragments and their position, as well as the possibility of interposition of muscular tissue between them, must be considered in order to institute proper treatment.—Helferich.

Balsam of Peru ranks next to iodoform in the treatment of tubercular affections of bones and joints, and if the latter remedy for any reason cannot be employed, or has failed in effecting the desired result, it should be given a fair trial if operative treatment is not urgently indicated.—Senn.

Œsophagotomy.—The incision should be made large enough to permit of comfortable manipulation without much traction. Blunt dissection is to be avoided, as the tissues are less viable and succumb to septic influences more easily when torn than when cut. The line of the incision is just in front of, and parallel with, the anterior border of the sterno mastoid muscle, beginning a little below the cricoid cartilage and extending to the sternal insertion of the muscle.—Gerster.

Correspondence.

LOGIC VS. SENTIMENT IN THERAPEUTICS.

To the Editor of the Medical Record.

Sir: The Record of November 18, 1893, contains an article on "The Treatment of Enteric Fever" which may prejudice and mislead practitioners.

Being responsible for the increasing use of the Brand bath in typhoid fever, by reason of having made the first pleas for it in the English language (New York State Medical Society, Medical Record, February, 1889) and by subsequent active propaganda for this life-saving measure, I may be pardoned for defending it whenever it is unjustly assailed. There is so much of real value in the article, for instance, the excellent directions for diet and hygiene, and the adverse view on quinine, that the reader may be misled into accepting some of its less reasonable views.

When the author would persuade as, however, that "favorable action is obtained from calomel in doses of seven and a half to ten grains every forty eight hours until four doses have been taken," the cautious practitioner must ask for the rationale of this "favorable action." The author answers that it is difficult to give this, but that the calomel "perhaps removes fecal matter, bacteria, ptomaïnes, and leucomaïnes; that it doubtless relieves to some extent congestion and inflammation of the intestinal mucous membranes; that it very likely, either in its own form or modified chemically, acts as an antiseptic, that it perhaps acts on the liver, and possibly as a nerve sedative." The sceptical practitioner will possibly, probably, or perhaps not be satisfied with this vague statement of "the principles and method of treatment for the dissemination" of which the article was written. He will, after carefully sifting the evidence adduced by the author, come to the conclusion that while it may be safe enough and probably useful to administer one full dose of calomel to clear out the alimentary canal in the beginning of typhoid fever, it would not be prudent to continue its use four times forty-eight hours, viz., well into the second or third week of the disease.

Less harmful, perhaps, but utterly devoid of a rationale, is the author's "specific treatment by one drop of carbolic acid and three drops of tincture iodine in a wineglassful of cold water every two hours," whose action he attempts to explain by the statement that "carbolic acid and iodine are valuable antiseptics, etc."

Whether two ounces of a solution of carbolic acid (about 1 to 1,000), and of tincture of iodine (about 1 to 300) are capable of disinfecting the intestinal canal, any tyro in medicine is able to decide.

It is not surprising that Dr. J. C. Wilson, who with Dr. Bartholow is quoted as the chief advocate of the treatment, has abandoned it in favor of the Brand method.

The author's horror of the bath treatment is really affecting, and is the chief reason for this communication. He says: "At present, bathing, according to the method of Brand, is enjoying an enviable popularity as a method of reducing temperature and preventing complication. This may answer very well in hospitals, where it makes no particular difference whether any individual patient dies or gets well, etc."

The depth and extent of the author's human sympathy for the sick is well illustrated by this statement. "Very likely" few hospital physicians show the author's indifference to the lives and comfort of the hapless creatures who seek relief at their hands.

This sentimentalist goes on to say in a fine (?) vein of irony, "Much testimony to the efficacy has been presented, but rarely has any one taken the pains to describe in print the piteous and ineffectual appeals to be spared the distress of further Brand baths, of patients who, in spite of a continuance of the baths, died. Such cases never occupy a very conspicuous place in scientific reports

on modern antipyretic treatment. The pathetic side of the story never appears in statistics."

Such an "argument" offered in lieu of statistics or clinical data, scarce requires refutation. But as this innuendo may serve to intimidate some practitioners in whose breasts "the milk of human kindness" abounds I propose to analyze its merits.

Before entering into cold facts and figures it may be interesting to reproduce the following humorous rhyme written by a physician who has been subjected to the Brand method.

TUBBING AS I HAVE FOUND IT.

When you have a little fever
Doctor B.'s a firm believer
  In the virtues of the "tub."
But, as often said before
(A score of years or more),
  "Aye, there's the *rub*."

Two stalwart nurses lift you
And very gently shift you
  From bed to water;
Which is so bitter cold
That you feel inclined to scold
  In a way you hadn't oughter.

The tub they nearly fill
So you sink in deep until
  Your head is in;
While you wonder in your heart
At the science and the Art
  Of Medicine (!).

But the casual observer
Sees you trust your life preserver
  Doctor B.,
Who with genial cheery manner,
Keeps a waving Hope's bright banner,
  This is all.

Soon your teeth begin to chatter
And you ribs begin to clatter
  Against the tin,
While you shiver and you quake
And you quiver and you shake
  Amidst the din.

You wriggle à la vermis
As they scrub your epidermis
  Cherry red.
When at last they fish you out
And you are laid without a doubt
  In your bed,

You are so very much at ease
That you forget about the freeze
  In the bath.
You feel like Pilgrim when his pack
Rolled clear off his back
  Adown the path.

ENVOY.

A-rub a-dub tub,
  How they rub
  How they scrub.
List to my roundelay,
  A little less tub
And a good deal more grub
  Is the song
I sing to-day

This patient is evidently satisfied with his experience. He is an attending physician to several hospitals, and is one of the most ardent advocates of the Brand method to-day.

As there is so much unreasoning doubt cast upon German statistics, I shall select for illustration of the "pathetic side of the story" the statements of two American authors. Dr. J. C. Wilson, Professor of Therapeutics in Jefferson Medical College, states[1] that "the average number of baths in each case was forty-two. As a rule the patients did not object to the baths. When they did so the objections ceased after a few baths had been administered." Dr. W. Gilman Thompson[1] describes his personal experience, having been treated by baths for an attack of typhoid: "It is not agreeable, at any time, to be taken out of a warm bed and suddenly immersed in cold water, but the after effect was so soothing and the favorable influence upon all the symptoms was so pronounced that the temporary discomfort was easily endured." "The pathetic side of the story" has evidently not been experienced by these careful observers.

Nevertheless, it is true that in about one fourth of cases in private practice great complaint is made during the last five minutes of the bath. Granting that all these make "piteous appeals," we would have, according to Dr. Wilson's table, $42 \times 5 = 210$ minutes, about three hours of "piteous appeals" for each case. For the sixty four cases treated by Wilson without a death by cold baths in the German Hospital, we must have $64 \times 3 = 192$ hours of "piteous appeals." According to Dr. Wilson's table, the mortality in the other Philadelphia hospitals averaged fifteen per cent. Hence the Brand method saved about ten funerals. How many days of anguish, misery, and sorrow were thus saved to the friends and relatives of these ten who were snatched from the grave with the sacrifice of one hundred and ninety-two hours of "piteous appeals," the pathetically inclined author may be able to calculate. These plain unvarnished facts are cited to soothe the sensitive natures, who, like himself, may be deterred from adopting this life-saving procedure on sentimental grounds.

The truly "pathetic side of my story," however, is to be found in the fact that in this day of broad knowledge and enlightment such an argument as "piteous appeals" should be brought forward in lieu of statistics or rationale. The conservatism of medical men is but too ready to accept prejudice in lieu of argument. Hence this effort to meet it.

While it may be true that the Brand bath will "never be generally adopted in rural districts, I do not concede that it will be so in private practice in cities." Here the intelligence of the community will force even reluctant and sentimental physicians to save the lives of their dear ones. Already the lay journals have taken up this subject and they will continue to probe it. In our large cities the best teachers are converts who a few years ago were sceptics. When men like Delafield, Draper, and Peabody teach it in one school and W. H. Thompson, Loomis, and Gilman Thompson in another, and when it is daily practised with brilliant results in the New York, Roosevelt, Presbyterian, St. Luke, Manhattan, and Austin Flint's and Peabody's service in Bellevue Hospital, the bright young men being educated at these schools and hospitals will not allow sentiment or irrational therapy to guide them. There is need of more positivism in medicine. Between two positive methods like the Brand method and chemical antypyretics, it did not require much time to decide. Intelligent physicians are abandoning the latter, and many who have the courage of their convictions are adopting the former even in private practice. Dr. H. B. Ball has recently had but one death in forty cases at the St. Luke's and New York Hospitals. It is my custom in private practice to place the choice between the bath and expectant method into the hands of the relatives, who usually leave it to my choice. Dr. Ball informs me that he has encountered no serious objection in private practice, although his ultimatum is the bath or a change of attendants. I have treated the wife of a physician who had witnessed similar treatment of another patient in his household; I have thus treated a case in a fashionable summer hotel without trouble. I have treated three members of the same family by baths in three successive years, and I have seen the same tub used by four different families, each obtaining it from the other at my suggestion. "Piteous appeals" did not deter even these

[1] In a paper read before the Forty-fourth Meeting of the American Medical Association, and published in the Journal of Balneology, August, 1893.

lay people from again permitting the use of the bath, sentiment and pathos must yield to logic and common sense in medicine. SIMON BARUCH, M.D.

51 WEST SEVENTIETH STREET.

THE CALOMEL TREATMENT FOR DIPHTHERIA. DEFENDING AN OLD FRIEND.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: My attention is directed to a paragraph in your issue of December 2, 1893, page 736, saying, "Dr. Hani writes from Elkhart, Ind., to say that Dr. W. H. Daly, of Pittsburg, Pa., does not advocate anything new when he, in his article in the RECORD of October 28, 1893, advises calomel in diphtheria." I beg to say again that I have never claimed anything new for this treatment, and if the doctor has done me the honor to read, even casually, any or all of the several articles I have published on this subject, he will find, not by reading between the lines, but by the lines and the words themselves, that I say in the outset and repeat the statement that the treatment is not new. The gospels of the Christian doctrine are not entirely new to some. Vaccination is not altogether new to the majority. Venesection is not new to others. The laws of gravitation are not new, yet they are all considered pretty good doctrines of their kind, and calomel treatment, though not new, and never claimed by me to be new, is yet none the less worthy of the most attentive consideration and trial; and if Dr. Hani, of Elkhart, Ind., has used the same with success for many years, that simply means that, even if the doctor has been wrong in believing I have claimed the treatment to be new, he is all right on the calomel treatment itself, and I am therefore pleased with the doctor's superadded testimony in its favor. But it seems as though it would be just as well for even Dr. Hani, of Elkhart, Ind., before he sits down to write a philippic, to see that he has a chair behind him.

I believe I am justly considered by my friends to be a good-natured man, and I am yet, notwithstanding that this is the third or fourth time I have felt called upon to publicly point, for my full justification for anything I have said about the calomel treatment, to the articles themselves. I append in foot-notes herewith the references which will fully control my statements on the subject, and I repeat I claim nothing new for it; but, nevertheless, the treatment will not disappoint the practitioner as often as other methods if begun early and kept up late, and in accordance with my instructions to the profession.

The medical profession are now gone mad after new remedies, and unless a remedy is new the author is sure to be told so. It is enough to give the average medical man nervous prostration to study the new remedies which appear in the various medical journals. Too many of them apparently based upon the trumped-up cases in practice by mercantile practitioners of medicine, who appear to be in the employ of wholesale drug-houses which are the owners of proprietary drugs. I honor medical advancement, but I shall not desert an old and tried remedy because it is an old-timer and simple in character, unless the newer one can be demonstrated to be better.

The late Sir Morell Mackenzie said once in my hearing, at the International Medical Congress, at Copenhagen, Denmark, of a new measure with questionable ear-marks on it, advocated by a German confrère: "I shall recommend my friends to try it, but I shall not feel safe in trying it myself, as my present methods are satisfactory and results fairly good." Faithfully,

W. H. DALY, M.D.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 16, 1893.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	10	8
Scarlet fever	71	6
Cerebro-spinal meningitis	3	2
Measles	267	7
Diphtheria	185	61
Small-pox	5	3
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Tuberculosis a Contagious Disease.—The following was presented at the last meeting of the Health Board:

"HEALTH DEPARTMENT, NO. 301 MOTT STREET,
"NEW YORK, December 13, 1893.

"HON. CHARLES G. WILSON, *President.*

"SIR: The report of Dr. Hermann M. Biggs, the bacteriologist of this department, relative to tuberculosis is, in the opinion of the Chairman of the Sanitary Committee, timely and well advised. The subject is well summed up in the three facts relative to the disease set forth on page 5, to wit:

"First, tuberculosis is a contagious disease and is distinctly preventable. Second, it is acquired by direct transmission of the tubercle bacilli from the sick to the well, usually by means of the dried and pulverized sputum floating as dust in the air. Third, it can be largely prevented by simple and easily applied measures of cleanliness and disinfection.

"The following recommendations, based upon the foregoing premises, are approved and offered to the Board for its consideration:

"First, that a circular be prepared for distribution among the people, setting forth the danger of contagion from tuberculosis, and the fact that the discharges from the lungs of tubercular patients are not only dangerous to others but also to the patient afflicted, and also setting forth the danger of expectorating in places where the sputum is liable to be dried, and carried by the air in the form of dust.

"Second, that physicians and other persons to whom the knowledge of the existence of a case of tuberculosis may come, be requested to report to this Department all such cases within seven days of the time when such sick person comes under observation.

"Third, the medical sanitary inspectors should, as a part of their duty, investigate doubtful cases of the disease reported, and take specimens of the sputa for diagnostic purposes, the same as is done in cases of diphtheria. These specimens should be transmitted to the Division of Bacteriology for examination, and the Division of Bacteriology should be properly equipped for such examination, for the purpose of obtaining definite knowledge upon which the proper sanitary surveillance of those suffering from tuberculosis can be based. Upon the verification of the diagnosis, the inspector should visit the physician reporting each case and request him to fully instruct his patient, and the persons with whom he is in contact, concerning the nature of the disease and the danger of its transmission. If the case be reported by laymen, or if the physician prefers that the inspector should assume the aforesaid duty, then the inspector should personally perform this service.

"Fourth, the following preamble and resolution should be adopted and sent to each of the general hospitals, and to the Commissioners of Charities and Correction:

"*Whereas*, tuberculosis is a contagious disease and is distinctly preventable, and

"*Whereas*, it is acquired by the direct transmission of the tubercle bacilli from the sick to the well, usually by means of the dried and pulverized sputum floating as dust in the air, and

Whereas, it can be largely prevented by simple and easily applied measures of cleanliness and disinfection, and, to an extent, by segregation of those suffering from it, be it therefore

"*Resolved*, That this Board urge upon hospital authorities of the city of New York, the importance of separation, so far as possible, in the hospitals of this city of persons suffering from pulmonary tuberculosis from those affected with other diseases, and urge that proper wards be set apart for the exclusive treatment of this disease, and be it further

"*Resolved*, That the Commissioners of Charities and Correction be recommended to take such steps as will enable them to have and control a hospital to be known as 'The Consumptive Hospital,' to be used for the exclusive treatment of this disease, and that, as far as practicable, all inmates of the institutions under their care suffering from tuberculosis be transferred to this hospital.

"Fifth, it is recommended that the disinfecting corps disinfect places where evidence of infection from tuberculosis exists, whenever in the opinion of the Chief Inspector of Contagious Diseases it shall be necessary.

"Sixth, it is recommended that suitable receptacles for sputa (cuspidors) be provided and properly cared for in all places where persons are brought together or caused to congregate for any purpose, especially in factory buildings.

"(Signed) Respectfully submitted,
"CYRUS EDSON, M.D.,
"*Chairman of the Sanitary Committee.*"

Health Department—Circular to Physicians.—During the last few months a series of investigations have been made in the bacteriological laboratory of the Health Department to determine how long the Loeffler bacilli remain in the throat after the disappearance of all false membrane in cases of diphtheria. The results obtained are extremely significant, and have caused the Department to establish a new rule regarding the discharge from observation of patients who have suffered from diphtheria, and regarding the time of disinfection of the premises.

During the past three months 405 cases of true diphtheria have been subjected to repeated bacteriological examinations performed at short intervals during the course of the disease and during convalescence. In all of these cases cultures were made at the beginning of the disease, again after the lapse of three or four days, and finally at short periods after the complete disappearance of the false membrane, until the throat was found to be free from the diphtheria bacillus. In 245 of these 405 cases the diphtheria bacilli disappeared within three days after the complete separation of the false membrane; in 160 cases the diphtheria bacilli persisted for a longer time, namely: in 103 cases for seven days, in 34 cases for twelve days, in 16 cases for fifteen days, in 4 for three weeks, and in 3 for five weeks after the time when the exudation had completely disappeared from the upper air passages. In many of these cases the patients were apparently well many days before the infectious agent had disappeared from the throat. These results show that in a considerable proportion of cases persons who have had diphtheria continue to carry the germs of the disease in their throats for many days after all signs of the disease have disappeared. No doubt the disease is largely disseminated by these persons who are apparently well, and who mingle with others while their throat secretions still contain the diphtheria bacilli.

These experiments have led the Health Department to adopt the rule, that no person who has suffered from diphtheria shall be considered free from contagion until it has been shown by bacteriological examination, made after the disappearance of the membrane from the throat, that the throat secretions no longer contain the diphtheria bacilli, and that until such examinations have shown such absence the case must remain isolated and under observation. Disinfection of the premises, therefore, will not be performed by the Department until examination has shown the absence of the organisms.

Secondary cultures, as in the case of primary cultures, may be made by the attending physician, if he so desires; otherwise they will be made by the inspector of the district in which the case occurs. This applies only to cases occurring in boarding houses, hotels, and tenement houses—not to those occurring in private houses.

In this connection an interesting observation has been made showing that in diphtheria cases which have been subjected to frequent irrigation with antiseptic solutions from the beginning of the disease the bacilli, as a rule, disappear far more rapidly than in those in which such irrigations have not been employed. The Department would feel grateful for any data which physicians of the city may furnish as to the treatment employed in each case in order that more reliable conclusions can be reached as to the best mode of treatment.

Shamelessness Extraordinary.—From a widely-scattered circular, appealing to the morbid fears of the sexual hypochondriac in the customary language, we quote: "In all cases where the organ is small, or where it has become relaxed through self-abuse, disease, or age, the conjestor, developing liniment, and nerve seeds should all be used at the same time.

The price of the conjestor is	$10.00
Three bottles of developing liniment....	5.00
Six packages of nerve seeds.....	5.00
One suspensory bandage	2.00
	$22.00

"When the whole course of treatment is ordered at one time, we will prepare and send by express to any address on receipt of $20.00." It is fully explained in other parts of the circular that the "conjestor" acts like a cupping-glass, the air being exhausted, etc. The drug-stores are acting as local agents in this execrable traffic. Is there no city law or State law in Chicago to stop it?—*Medical News.*

The Breeding-place of Neurologists.—In his opening address as chairman of the Neurological Section of the Pan-American Medical Congress, Dr. Hughes gives an extended review of the contributions of American workers in this branch of medicine. He shows that Dr. Benjamin Rush taught that inebriety was a disease. The idea lay long dormant, but finally it was recognized and developed until the causation, pathology, and treatment of this disease is tolerably well understood. Having given in brief America's record, he says: "America breeds and develops neurologists as the water breeds and develops fishes. The pabulum neurology feeds upon is in the American people—their hustling, rushing habits, their business, professional, social, and political environment, and the numerous newspapers they read before breakfast, and every night before they forget to say their prayers; this moral, political, social, and business atmosphere of ambition and bustle tends to develop the strongly endowed, neurologically and psychologically, as it tends in the weakly endowed to the development of neuropathic conditions. It develops neurologists and psychologists to care for the neuropaths. It builds and breaks the nervous system. It cannot be said that we are a neuropathic people, though we are tending that way; but neurology is advancing with equal pace with neuropathic break down, and will, it is hoped, ultimately enlighten and save the people from their neuropathic sins." Thus the food upon which neurologists thrive is the physiological sins of the American people. As these are great, so do neurologists grow fat and rich in this world's possessions.—*American Lancet.*

STATE AND MUNICIPAL CONTROL OF INFECTIOUS AND CONTAGIOUS DISEASES.[1]

BY JOHN WINTERS BRANNAN, M.D.,

PHYSICIAN TO BELLEVUE HOSPITAL, NEW YORK.

THE subject of public health has engaged the attention of law givers from the earliest ages, but it is only during the present half-century that much has been accomplished in the way of effective sanitary legislation. England, profiting by her experience with cholera, was the first nation to recognize the full importance and necessity of public hygiene. The Public Health Act, enacted by Parliament in 1848, was the beginning of a series of measures which have given that country the most perfect sanitary code in the world. It is not to our purpose to review this legislation, but it may be well to note briefly some of the results obtained by it. The average annual death-rate throughout England and Wales, during the twenty years previous to 1870, did not vary greatly from 22.5 per thousand of the population, and it was estimated by Mr. John Simon that one hundred and twenty-five thousand persons died each year of diseases due to defective sanitary conditions. Although Simon's figures were thought by some to be exaggerated, they nevertheless had great weight in persuading Parliament to adopt the reforms recommended by him. During the succeeding twenty years improvements on a large scale were carried out in all the large cities and towns throughout England and Wales, with the result that in 1889 the annual mortality had fallen to only 17 9 per thousand, thus more than justifying the calculations of Simon. The life of a human being has been estimated by Farr to represent a capital of $800. At this valuation the one hundred and twenty-five thousand lives now saved in England are equal to a money saving of one hundred millions of dollars annually.

The work accomplished in England has attracted the attention of other European countries, and they have all attempted to imitate her methods, but not all with the same degree of success. Sanitary laws must of necessity restrain the liberty of the individual, and can, therefore, never be thoroughly successful unless their provisions appeal to the intelligence and honest conviction of the public. The fact that in England these laws are made by the people themselves through their representatives in Parliament, aids much in securing their thorough enforcement. In our own country the conditions are equally favorable, except that here the power to enact such laws rests with the State and not the national legislature. The Supreme Court of the United States has decided [2] that all those powers which relate to merely municipal legislation, or what may be called internal police, are not surrendered to the general government; that consequently, in relation to these, the authority of each State is supreme and exclusive within its boundaries. Among these powers are inspection laws, quarantine laws, and health laws of every description. The State having thus all the power necessary for the protection of the health of the people, may delegate to corporations organized for local self-government the power of legislating with regard to such matters. The power remains, however, at all times subject to the control of the State, and may be resumed or cut down by the legislature at its discretion.

Municipal corporations are then to be considered simply as agents of the State, organized for local government. As the preservation of the lives and health of the people is one of the chief purposes of local government, reasonable regulations in relation thereto have always been sustained as being within the authority of these corporations. Municipal regulations must naturally interfere in some degree with the free exercise of private rights, but should not do so unnecessarily. As this so called police power is conferred for the purposes of self-defence, it must not be carried beyond what is necessary for protection.

In the State of New York and in many other States of the Union, the legislature makes a distinction between the larger and the smaller municipal corporations or cities, generally in the direction of giving larger powers to the former The powers to make sanitary regulations for New York City are contained in the Consolidation Act, and are conferred directly upon the Health Department. In considering the means employed by the Board of Health to control infectious and contagious diseases, I shall limit myself to those measures which bear most directly upon the subject. Pure food, pure water, pure air, and generally good sanitary conditions are of course indispensable and must be striven for at all times, but something more than these is called for to check the spread of contagious disease. The measures I refer to are compulsory notification, isolation, and disinfection. Under the head of isolation I include the power to remove the patient to a special hospital, if he cannot be efficiently isolated at home.

All of these measures are important, though perhaps not to the same degree. A law requiring the notification of infectious diseases is now in force in all the principal cities of this country, as well as in all the capitals of Europe. French physicians have always strenuously opposed the passage of such a law, maintaining that it involves the violation of professional secrecy. The Chambers, nevertheless, enacted the law about one year ago, and its provisions went into effect throughout France on the first of the present month. The opinion of the Paris Academy of Medicine was simply asked as to what diseases should be classed as infectious and contagious. There is a wide divergence of opinion and practice on this important point. In Chicago, typhoid fever is not reported, in Philadelphia and London measles is not deemed worthy of notice, in other places whooping cough is excepted, in others erysipelas.

This lack of agreement is probably due to the fact that there is still some confusion as to the exact significance of the words infectious and contagious. The old meanings no longer fit our present more definite conceptions of these terms, based upon the teachings of bacteriology, and yet it is difficult to use the old words without calling to mind the ideas formerly connected with them.

Dr. Prudden [1] defines an infectious disease as one which is caused by the invasion and reproduction within the body of pathogenic micro-organisms. According to the same authority, an infectious disease is contagious when the micro-organism which causes it can, under the ordinary conditions of life and by whatever means, be conveyed from the sick to the well in a condition capable of lighting up the disease anew. Dr. Prudden, however, insists upon the importance of recognizing the great difference

[1] Remarks before the Section of Pediatrics of the New York Academy of Medicine, December 14, 1893, during a discussion on scarlet fever.

[2] Parker & Worthington: Public Health and Safety, page 3.

[1] New York Medical Journal, 1892, vol. lv, p. 421.

in the degree of contagiousness which different diseases may possess.

These definitions of "infectious" and "contagious" are generally accepted by bacteriologists at the present day. As thus defined, each term has its own special field of application. An infectious disease is the morbid condition produced within the body by the entrance of pathogenic micro-organisms. There is no limitation as to the source of the infection, nor is the possible communicability of the disease suggested. The term infectious does not look beyond the individual already infected. Contagious, on the other hand, has gained what infectious has lost. It now includes all modes of conveyance of infectious disease. It is no longer a question of the manner of transmission, whether by direct contact or through the air or by other carriers of infection. If an infectious disease is communicable to others by any means whatever, it is also contagious. Contagion presupposes infection, therefore all contagious diseases are infectious, but not all infectious diseases are contagious.

It is surely a great gain to have thus simplified the meanings of terms, but it is unfortunate that in simplifying them we have also changed them. To us, as medical men, it perhaps does not matter that we have taken such diseases as typhoid fever, cholera, and tuberculosis, formerly called simply infectious diseases, and placed them side by side with small-pox and scarlet fever, diseases known to all as directly contagious by simple diffusion through the air. We know that there are degrees of contagiousness, using the word in its new and broader sense. But it is otherwise with our patients, who have not followed the steps by which we have arrived at our present understanding of infection and contagion.

I have discussed this question of nomenclature somewhat at length because it is especially important at this juncture that the public should understand what is meant by the term "contagious disease." Dr. Biggs, the pathologist of the New York Board of Health, has recently made an official report to that body, in which he advises that physicians practising in this city should be requested to notify the Board of all cases of pulmonary tuberculosis coming under their observation. I believe that the majority of physicians in New York will agree entirely with the spirit of Dr. Biggs's recommendation and will aid the Board of Health in carrying it out. But I also believe that there is a considerable proportion of physicians in the city who will be less willing to report the names of their private patients who are suffering with tuberculosis, if this affection is to be termed a contagious disease. They know the alarm that enters a household when a disease is declared contagious, associated as it has been in the past with enforced isolation of the patient. I would therefore suggest the use of the word *communicable* in place of *contagious*, and not only for tuberculosis, but for all diseases of this class. Communicable expresses exactly what we mean and no more, whereas contagious produces a false impression, due to the former meaning of the word.

If the term communicable is adopted to include all those infectious diseases which are capable of transmission in any mode whatever, then contagious may still be retained, but restricted to its old use. It would then include, as a sub-class of communicable diseases, such diseases as the exanthemata, whooping-cough, and mumps, which are conveyed by simple contact, direct or indirect.

Lest some may think that this change of nomenclature is impracticable, I will call attention to the fact that the State Board of Health of Michigan has for years used the term "dangerous communicable diseases" for all diseases requiring official regulation in the interests of the public health. I do not know what reasoning or experience led that Board to the selection of this term, but it has served it well in the action taken by it some three months ago, when it resolved that hereafter, tuberculosis should be included in the official list of "Diseases dangerous to the public health," requiring notice by householders and physicians to the local health officer as soon as such a disease is recognized. In this resolution the question of isolation of the patient is not mentioned. Its purpose is to secure to the health authorities knowledge of the location of each case of the disease, with the view of placing in the hands of the patient and his friends information which will enable them to prevent its further spread. Leaflets giving this information and entitled, "Restriction and Prevention of Tuberculosis," are distributed throughout the State by the Health Board. In these leaflets the disease is called communicable, and the mode of communication is clearly stated.

Although Michigan is the only State which has taken official action in the way of restricting tuberculosis, other parts of the country are also awake to its necessity. Two circulars, similar to the one I have mentioned, are published and distributed gratuitously, one by the Health Department of Providence, the other by the Pennsylvania Society for the Prevention of Tuberculosis. The language of both circulars is excellent, except that in both the disease is termed "contagious."

As we are about to follow the decided step taken by Michigan, let us in like manner call tuberculosis by its right name, a communicable disease.

I shall say but little regarding the other measures of restricting infectious disease, as they are to be fully discussed this evening by others. In the case of a purely contagious disease, such as scarlet fever, notification of the disease would of course be of little value unless it were followed by prompt isolation of the patient and disinfection of the premises at the termination of the illness. Under the conditions which prevail in New York it is seldom possible to secure efficient isolation of the patient at home. It is, therefore, very unfortunate that there exists in this city such a prejudice against removal of the patient to a contagious disease hospital. In London there are sometimes as many as three or four thousand cases of scarlet fever in the Metropolitan Asylums Board hospitals at one time. In that city even well-to do people seek admittance to the fever hospitals, and many are turned away for lack of room. In New York, during the whole of the year 1890, only 324 patients were taken to the Willard Parker Hospital, a number too small to have much effect in restricting the spread of scarlet fever in the city. In Boston, also, it has been found that the disease prevails epidemically, or to only a slight extent, without much regard to the restrictive measures of the health authorities. But it is the intention, in both New York and Boston, to forcibly remove many more cases to the isolating hospitals as soon as the new buildings, now under construction, are completed.

In closing, I will again instance the experience of Michigan in order to show what can be accomplished under favorable conditions by efficient isolation combined with disinfection. During the year 1889 there were 417 outbreaks of scarlet fever in that State. In 72 of these outbreaks, isolation and disinfection were both neglected, and the number of cases per outbreak was 16.78. In 52 outbreaks, both isolation and disinfection were strictly enforced, with the result of limiting the number of cases to but 2.69 per outbreak. In many outbreaks one restrictive measure was enforced and the other neglected. In all such instances the spread of the disease was checked somewhat, but never to the same extent as when both isolation and disinfection were enforced.

Salicylic Acid for Coryza —Dr. A. J. Wegg, of Spanish Town, Jamaica, deems salicylic acid, when employed as an errhine, a reliable agent for the arrest of coryza. A few drachms of the dry acid are placed in an ordinary paper pill-box, in the cover of which small pinholes are made. Before using, the contents of the box is shaken, and then the nostrils applied to the openings. This may be repeated time and again until sneezing is induced, as demanded, or as indicated by the amount of hyperæmia of the nasal mucous membrane.—*Medical Age*.

MULTIPLE CONGENITAL DEFORMITIES WITH ARREST OF DEVELOPMENT, MORE ESPECIALLY A DEFORMITY OF THE HAND RESEMBLING "WALRUS FIN."[1]

By V. P. GIBNEY, M.D.,

NEW YORK.

Some fifteen years ago an unusual type of deformity came under my observation, and I was unable to classify it at that time. The advice I got on the subject was unsatisfactory, and it was many years again before I saw a similar case. In fact, it was ten years later before a second case came under my observation. About two years later I saw a third case in Philadelphia, in the practice of Dr. De Forest Willard, and in January, 1891, a fourth case came under my care. So that, with three, at least, for a study, I have felt the subject of sufficient interest to present this evening for a discussion.

Just what to call the cases, other than general arrest of physical development, I do not know. The etiology is, of course, as in all these cases of congenital deformities, obscure. I am at a loss to give any explanation for these rare occurrences. In the true sense of the term, they may certainly be regarded as Lusus Naturæ. Ordinarily we understand a Lusus Naturæ as a deficiency or a defect of some kind that cannot be remedied by any treatment. Still, I do not know whether this will be accepted as a legitimate definition or not. I hesitate, however, to speak of these cases in this light, because they are amenable to a great amount of relief, and the simple narration of the cases will satisfy my hearers that a vast amount of good can be accomplished by persistent and systematic mechanical and operative treatment, intelligently carried out. Fortunately, I am able to present the cases themselves this evening, and they are here for your inspection.

Case I. *Arrest of Development of Hands and Patellæ, Bi-lateral and Symmetrical, Complicated with Genu-valgum.*—A. N——, a boy six weeks of age, was brought to me in the Out-patient Department of the Hospital on July 28, 1879. I failed at that time to make as full a record of the case as I should do at present, but some notes were jotted down, and in this way I am enabled to recall many of the features. I noted, for instance, that there were contractures of the flexors of the ring and little fingers on both hands, that there was a deformity of the feet simulating club-foot, which could be easily overcome by manipulation, that the knees were not well developed. The mother was instructed to manipulate the fingers and foot.

It was noted on December 1st, five months later, that the contracture of the hands had in a measure been overcome, but that the tendo-Achillis and the flexor longus pollicis remained shortened.

On December 24th we made a more thorough examination, and could find no trace of patella on either limb. The late Dr. Frank H. Hamilton, who was at that time a member of our consulting staff, saw the patient for us and presented it at his clinic. He wrote me as follows:

"Dear Doctor: I do not find any patellæ. The case is very interesting, etc.

"Very sincerely,
"F. H. Hamilton."

I remember examining the case frequently in search for the patellæ, and, after a while, I was pretty sure that I discovered rudimentary bodies on the outer side of the thighs, lower third, and my impression is that I was enabled to convince Dr. Hamilton that they were present, although quite rudimentary.

The case was under pretty close observation and treatment for the next eighteen months, and at the end of this period we had no difficulty in recognizing the patellæ. In order to overcome the knock knee, apparatus was worn, which apparatus, with a foot-piece, enabled us to extend the Achilles tendons and get the feet into very good shape. The hand muscles and the leg muscles were still small at that time, and nothing was done specially to increase their development. It was noted also that the thigh muscles, those anteriorly, were small.

It was noted on February 18, 1881, that he was walking without support, but was still compelled to use the apparatus for the correction of his deformity. As late as September 30, 1881, the report was that he stood quite straight—the limbs were much stronger.

I saw nothing further of the case until October 14, 1893, when his mother was advised to bring him to see me again by my friend, Dr. Edward S. Bunker, of Brooklyn. I made the following note: "Goes to school. He walks very well indeed, except that he wears his shoes off very rapidly at the ball, especially on the right side. He shows very little deformity as he walks—walks long distances. As he lies on the table, his knees are in slight genu-valgum, can't be fully extended, come down to about 165°. Can flex to about 120°. The patellæ are pretty good sized now and are in very nearly normal position, say about an inch too high and a half inch out of

Fig. 1.—Rear View of Case II. before Treatment.

Fig. 2.—Front View of Case II. before Treatment.

the way to the left. The comparative measurements of the knees: Right side, 8½, 10, 9½; left, 8¾, 10, 9¾; right calf, 9¼; left calf, 9¼.

Case II. *Congenital Talipes-equino varus, Extreme, with Arrested Development of Hands and Fingers, of Knees, Patellæ Rudimentary and Displaced, Marked Genu-valgum.*—K. K——, a girl about eight years of age, whose family history was negative, was admitted to the hospital June 18, 1889. She was well nourished, but walked with characteristic club foot gait, the plantar surface not touching the floor. Calves were undeveloped. The movements of the toes were limited. The hands exhibited a peculiar lack of development, in that the thenar and hypothenar eminences were practically nil, fingers were elongated and unshapely. The knees were in marked genu valgum. The patellæ were small and were dislocated upward and outward, toward the outer and anterior aspect of the thighs, lower fourth. (See Figs. 1 and 2, showing the front and rear view.)

On manipulating the parts one found that the deformity could be corrected a good deal without the employment of a great amount of force, and it was decided to treat the knees and feet by repeated applications of plaster-of-Paris, correcting as much as possible at every sitting. The Achilles tendons were found, at a later examination,

[1] Presented at the Practitioners' Society as A Study in Congenital Deformities, November 3, 1893.

to be quite short, and the first application of plaster was made under ether on June 21st, when the Achilles tendons and the tendon of the tibialis anticus, as well as the plantar fascia, were divided subcutaneously, that we might the easier improve the position of the feet.

On July 20th, August 12th, and August 19th, the plaster-of Paris was removed, the deformity still further corrected by manual force, including the knock-knee, and plaster reapplied, extending from the upper third of thighs to the toes.

On September 20th, under ether again, the feet were brought into a still better position by manual force. It was then found that the deformity of the right foot was very nearly corrected.

October 29th, under ether, tendo-Achillis of left foot was divided again, and the foot was brought up in dorso-flexion to an angle of about one hundred degrees. It was not possible to force it into better position, as the motion from this point took place only at the mid-tarsal joint, and not at the tibio-tarsal joints.

From January 7, 1890, to October 28th, ether was administered frequently, every three or four weeks, and the deformity partially corrected at each sitting. It was found, however, that the relief was not permanent, that the deformity would relapse on the slightest provocation.

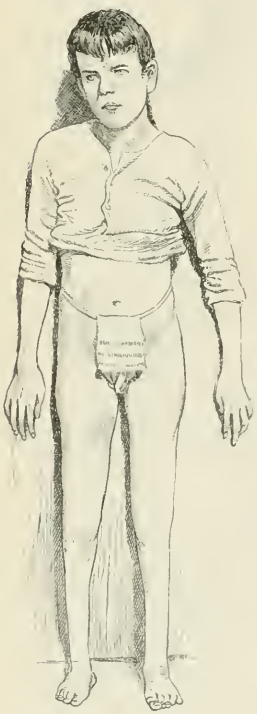

FIG. 3.—Front View of Case II. after Treatment.

FIG. 4.—Rear View of Case II. after Treatment.

The head of the astragalus on each foot could be felt distinctly, and seemed to be displaced forward, and it was thought that this bone interfered with the correction of the equinus.

Under ether, October 28th, the astragalus of right foot was enucleated and part of the cuboid, before the foot could be brought into excellent position.

The parts healed promptly, by December 2d, and, on December 16, 1890, the astragalus was removed from the left foot.

It was noted on the 23d, that the wound had become septic from some reason, and a wound remained, which, by the latter part of the month, had very nearly healed.

On January 19, 1891, she was examined for record, and it was found that the hip movements were normal, that both knees could be flexed to an angle of one hundred and forty-five degrees, and extended to an angle of one hundred and eighty degrees. It had been difficult, I omitted to mention, all along to flex the knee, and whenever the plaster was applied, not only was an effort made to correct the knock knee, but to stretch the quadriceps femoris tendon by flexing the joint a little. The right foot at this time could be flexed to eighty degrees, the left to one hundred degrees, and there was a range of motion on the left side of about ten degrees.

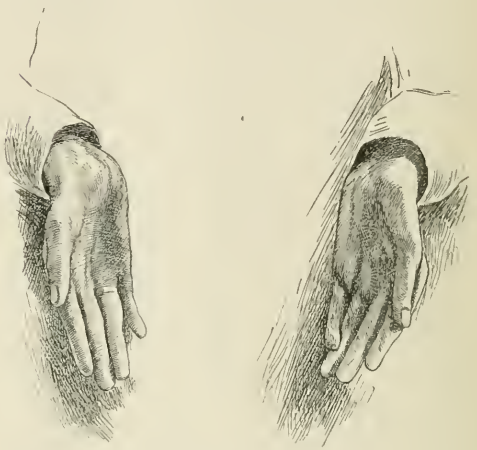

FIG. 5.—Appearance of Hands in Case II

On September 30, 1891, apparatus was employed in the shape of knock-knee springs, as her feet were giving us no longer any special trouble.

In November of that year our attention was called to a peculiar symmetrical contraction of the second toe, as shown in the photograph. This deformity of the toe made it exceedingly difficult to have her wear apparatus, and especially shoes, so that it was necessary to correct this extreme flexion of the toe. Ether was required to accomplish this.

By May 17, 1892, the feet were not in the best position, and a little force was employed to prevent this tendency to deformity.

On September 16th we had to administer ether again, and put both feet up in the extreme dorso-flexion. This had to be repeated on November 11th.

On January 12, 1893, it was noted that she stood squarely on the floor, and that there was very little, if any, tendency to inversion. In the left foot there was slight valgus That is to say, the foot was practically a flat foot, but the rotation of the whole limb was inward and gave a rather awkward appearance as she walked. There was no voluntary power of flexion nor extension of the ankles, but she had ability to flex and extend the toes. The knees could be flexed to about one third the normal range. Calf muscles were poorly developed. She was still wearing apparatus to maintain the good position.

At present the appliances are still worn, because we fear that there will be a relapse again if she is not kept under close observation. Looking at the photographs when she came into the hospital, one can easily note a decided improvement. (See Fig. 3, which shows her condition to-day.) When we consider how good a result is noted in Case I., it is fair to presume that this patient will be equally fortunate, and a good prognosis can, therefore, be given. She is able to use the hands for

ordinary purposes, and can even do needle-work. (See Fig. 5, from photograph.)

I do not recall any case of equino-varus that has proved so obstinate as has this one. Time and again I have felt that the cure was complete, and then, after several months, while still in the hospital, it would be found that the deformity had slightly recurred.

Case III. *Congenital Equino varus, with Multiple Deformity Affecting the Shoulders, Elbows, Hands, Hips, and Knees.*—On January 9, 1891, a physician of a neighboring town brought his baby, E. O'G——, a girl, aged three months, to see me, and, after making an examination, I felt utterly helpless in the matter of relief. I advised him to wait and let me study the case.

However, I noted at the time that the baby was hearty and well nourished, that the arms and forearms were held in inward rotation, so that the palms looked backward and outward; the arms were kept rather close to the side; shoulder-joints were pretty free in certain directions, though it was difficult to rotate the arms outward; there was no other deformity about the shoulder joints; the pectoral muscles were evidently shortened; the elbows were held in very slight flexion, in fact, they were nearly straight; it was difficult to effect flexion to ninety degrees without great pain; the hands were small, the palmar fascia shortened a little, the thumb drawn into the palm; the muscles of both upper extremities were small, especially in the hands, which were rudimentary. The lower limbs presented the following deformities: There was slight subluxation forward at the hips, the joints here not being as free as they should be; the thighs were rotated outward, so that the top of the feet looked directly outward. The baby could voluntarily flex the knees to ninety degrees, passively they could be flexed to an acute angle; patellæ were small, but in normal position; the joints themselves seemed normal so far as one could make out by manipulation. The feet were in marked equino-varus. There was a lack of symmetry of the head in front, the right side being slightly flatter than the left. The child was born at full term, was bottle fed, but seemed to be thriving. At birth the arms were in pretty much the same position as at the time of my first examination, but the feet were crossed, the limbs one over the other. Since birth the child had improved a little under manipulation of the different joints.

On March 22, 1891, under ether, I succeeded in pulling the head of the femur down into the acetabulum on right side. That is, I was able to cause disappearance of the hard tumor over the ramus of the pubis and to flex the thigh, to adduct, and to rotate. It was very difficult to rotate the limb inward, however, but this was accomplished by considerable force, so that the patella came in front. A little force was employed on the left side, and and the limbs brought down equal in length. The Achilles tendons were divided, and, by a trace of moulding and manipulation, the feet were brought into position of calcaneo valgus, just the reverse of what they were. Care was taken to hold the feet and limbs into good position while plaster-of Paris was applied from the toes up to the axilla, special pains being taken to pad the parts well and cut out sufficiently about the genitals to avoid excoriations. The patient took very little ether, but was completely anæsthetized so far as the reflexes went. It cried and moaned during the whole operation.

On March 28th, six days later, the baby was brought to my office, and it was reported that for the first few days she was very restless and seemed to be suffering a great deal, but for the last two or three days was comparatively comfortable. The plaster was soiled and broken in one or two places. The deformity had not recurred, and, on removing the plaster there was found no excoriation whatever. The dressing was renewed.

By the latter part of April the child was placed in a wire cuirass. During the summer months it was difficult to keep any apparatus on, but the mother persisted, and after a while the cuirass was replaced by a pair of light club-foot shoes.

Up to the fall of 1891 no attempt had been made to correct the deformity of the shoulders or elbows. Indeed, the winter was occupied in maintaining what had been gained, and re-correcting deformity after slight relapses.

On February 1, 1892, it was noted that the hips were in very good position. There was no dislocation when thighs were flexed. Elbows could be flexed to ninety degrees. Child was beginning to use its hands. It was still difficult to keep the feet in normal position.

April 25, 1892, the limbs were equal in length, no dislocation at hips. A moderate amount of force upward did not cause any subluxation, even. She could sit up. The right thigh was rotated outward a good deal and did not admit of adduction without considerable force. It was difficult to flex the right foot to ninety degrees. The left foot could be brought a little beyond this point.

In the spring of the present year she was subjected to still further treatment in an operative way, and at the same time an apparatus was made to assist in flexing the elbows and to correct the inward rotation of the arms and forearms. This was a spinal brace, with pieces over the shoulder to which arm-pieces were attached.

During the summer the child has worn the apparatus two or three hours, at least, every day, and the muscles

Fig. 6.—Represents a hand very similar to that of Dupuytren's contraction, but pathologically unlike it.

are already very good. She begins to use the hands and elbows more freely, and it is believed that this deformity can, in time, be completely overcome.

Thus I present, in detail, the notes of three cases. The fourth, as above mentioned, was seen in the practice of Dr. Willard, of Philadelphia, and I do not know what the result has been. I have not made a diligent search of the literature, but present them simply as a clinical contribution to the study of congenital deformities, a study which will assist materially in the correction of these deformities and will enable us to give, at least, an encouraging prognosis.

P.S.—The week following the presentation of this paper I saw, through the courtesy of Mr. S. M. Evans, a medical student at the College of Physicians and Surgeons, a patient who presented the same deformity of the hands, only a little more exaggerated. He is a blacksmith, thirty years of age, and presented a pair of hands from which I obtained a photograph shown in Fig. 6. I have been awaiting an opportunity to examine him more thoroughly, but learned this much at the time I had his photograph taken. He has, as far back as he can remember, presented this "walrus fin" hand. He finds the hand very useful, although he can't extend the fingers or the thumb. One looking at it would recognize a Dupuytren's contraction, but on close examination it is

found that the fascia is not involved, but that the skin is atrophied and shortened, and seems to be the chief factor in the production of the deformity. He tells me, furthermore, that his only child, a baby in arms, presents a deformity exactly like his own. This patient I have not seen, but I am promised an opportunity for observation. Dr. Abbe at the close of the meeting suggested the term "walrus fin," as aptly representing the deformity in question.

A CASE OF THORACOPLASTY FOR THE REMOVAL OF A LARGE CICATRICIAL FIBROUS GROWTH FROM THE INTERIOR OF THE CHEST, THE RESULT OF AN OLD EMPYEMA.

By GEORGE RYERSON FOWLER, M.D.,

SURGEON TO ST. MARY'S HOSPITAL, AND TO THE METHODIST EPISCOPAL HOSPITAL, BROOKLYN, N. Y.

F. E. S——, aged thirty-five, female, married, was admitted to the Methodist Episcopal Hospital on October 5, 1893, with the following history: With the exception of an uncle on her mother's side there is no history of pulmonary disease in the family. In May, 1886, the patient consulted a physician on account of a "squeaking" sound which she herself heard and felt, and which bystanders could also distinctly hear, in the lower portion of the right chest, when she took a deep inspiration. Upon examination she was informed that she was suffering from "fibroid phthisis." Her general health had not been good for some time prior to this, but she does not recall at this time that cough was a prominent symptom.

In March of 1887 she suffered an attack of pneumonia upon the right side, which seemed to run the usual course, as far as can be learned from her statements.

On January 31, 1891, following an attack of "La Grippe," so-called, during which cough was a prominent symptom, it was discovered that her right chest contained fluid. She was treated by blisters, and some internal medication to promote absorption. These measures were ineffectual, and in the following March the attending physician removed, by means of the aspirator, about sixty ounces of what was stated to be sero purulent material. At the end of two weeks another aspiration was performed, the result of which was about thirty ounces of bloody fluid. At intervals of two weeks a like amount of fluid, each time more decidedly purulent, was withdrawn. Five aspirations in all were performed.

In June, 1891, permanent drainage was established, a small rubber tube being introduced between the fifth and sixth ribs.

During the time that has elapsed since the first introduction of the drainage-tube the patient has never been able to dispense with the latter. Antiseptic irrigation of the cavity was practised quite regularly, and in the course of the next five years there was apparently but a very small space which would contain the irrigating fluid; all efforts to close this, including curetting, stimulating injections, etc., failed, however.

Examination showed a sinus with a depressed external opening lined with integumentary tissue, leading from the site of the latter between the fifth and sixth ribs directly inward for a distance of about five inches. Toward the bottom of this cavity the probe deviated in an upward direction and entered a small cavity. About midway between the inner termination of the sinus and its external opening the probe encountered a knob-like projection. With a strong light a rounded body could be seen rising and falling with each respiratory act.

An area of dulness extended vertically in an upward direction from the lower border of the liver to the level of the third rib. Vesicular murmur was found to be present upon auscultation at the apex; this gradually diminished in a downward direction until the area of dulness was reached, at which point it disappeared altogether. The heart was displaced to the right of the sternum. More or less purulent discharge had existed for a greater portion of the time since the drainage-tube had been placed in position, five years before. The patient stated that any attempt to dispense with this was followed by an accession of febrile symptoms.

The patient's general condition was fair. The urinary secretion was diminished to about two thirds of the daily normal amount, although no albumin or casts were present. There was no cough.

On October 7th, the following operation was performed: An elliptical-shaped vertical incision, four inches long, was made in the axillary line extending downward from the fourth rib, so placed as to include the orifice of the sinus. The soft tissues were retracted from each edge of the incision, the chest-wall cleared, and about three and a half inches each of the fifth and sixth ribs removed. There was then revealed a mass of cicatricial tissue which was firmly attached to the chest-wall, and through which the sinus passed in the direction of the median line of the body. This mass was isolated by blunt dissection from its attachments to the chest wall. As the dissection advanced the mass increased in size, until it was found to extend, in a downward direction, to the diaphragm. It was peeled off from the latter until its limit toward the median line was reached. Here it was found to rest against the displaced pericardium. By making strong traction and working with the tips of my fingers, occasionally employing the curved blunt scissors where the adhesions were particularly dense, I at last succeeded in detaching it from the last-named structure. The movements of the diaphragm, as well as those of the heart, impeded the dissection, and great care was needed to prevent wounding the important parts in the neighborhood. The mass was lifted from the cavity of the chest, and finally detached from the lung above.

During the operation hemorrhage was held in check by crowding dry sterilized gauze behind my fingers and exerting considerable pressure thereon. During the separation of the mass from the lung bleeding was quite free, but when this was finally accomplished the hemorrhage ceased almost entirely. But a single vessel required the clamp, and this was in an adhesion on the pericardial side of the mass. As the mass came away a hiatus was left which represented the lower three-fifths of the right cavity of the chest.

Oozing from the surfaces of the cavity was checked by gauze pressure. The heart's action could be accurately studied as this organ beat tumultuously in the depths of the cavity. The latter was tamponned with iodoform and zinc-oxide gauze, the external wound dressed with the same, and the whole secured in position by a chest-binder.

The patient suffered considerable shock following the operation. She soon rallied, however. The breathing did not seem to be greatly embarrassed, but the heart evidently resented the pressure made by the tampon. The pulse remained alarmingly frequent for the first twenty-four hours, at the end of which time it was considered advisable to remove the tampon. It was only necessary to tampon the cavity lightly thereafter, following which the pulse-rate fell from 160 to 120 to the minute. The temperature reached 102° F. within the first twenty-four hours and then fell to 101° F., where it remained for the following three days, from which time on it fell to within a fraction of a degree of normal, save upon one occasion when some digestive disturbance caused an elevation to 100.3° F.

The cavity was irrigated once daily with a 1 to 1000 Laplace solution of mercuric chloride (mercuric chloride, 1 to 1000; tartaric acid, 5 to 1000); what remained of this solution was subsequently washed away by the plasma salt solution. Upon each occasion the cavity was thoroughly dried out and re-tamponned with oxide of zinc gauze. As the lung expanded, a space developed behind the latter which required considerable care to properly cleanse and drain.

The heart gradually receded from its abnormal position, and the granulating tissue, under the stimulating influence of the gauze tampons, together with the expansion of the lung-tissue in the upper portion of the cavity and the collapse of the chest-wall due to the resection of the ribs, gradually closed the cavity. The capacity of the latter progressively diminished until, from holding nearly thirty-two ounces, it finally held less than an ounce. The gauze tampons were now omitted on account of the partial closure of the external opening and the difficulty of dressing in this manner without enlarging the latter. Larger drainage-tubes placed side by side were substituted, and these gradually abandoned as the cavity contracted. Finally, the cavity held less than a drachm, and as this represented about the space occupied by the tube itself, this was omitted altogether. Thereupon the external opening rapidly closed. This took place in just twenty eight days from the time of the operation.

At the present time the patient is apparently well. She is gaining rapidly in weight and strength, and attends to her household duties as if nothing had ever happened to her. The chest-wall has sunken to about an inch and a half below its former level at the site of the resection of the ribs. The normal respiratory murmur is present posteriorly down to the level of the seventh rib; anteriorly, it can be heard down to the fifth rib. Complete flatness exists in the area in which the vesicular murmur is absent. The heart has receded until the apex-beat appears to the left of the sternum.

The report of the pathologist, Dr. Eugene Hodenpyle, upon the growth removed, is as follows:

The mass removed consists of exceedingly dense fibrous tissue, containing here and there bits of cartilage and osteoid tissue. A fistulous track extends the length of the specimen, lined by dense layers of epithelial cells, beneath which are many rudimentary sebaceous glands. A number of sections revealed in places the epithelium, arranged in such an irregular manner that portions seem to be included in the fibrous tissue so as to suggest at first glance, epithelioma. In none of the sections can any structures be found which in any way resemble lung tissue.

Viewed in the light of the pathological findings, taken in connection with the clinical history, the case seems to be one in which a fistulous tract, lined with integumentary tissue continuous with that of the chest-wall, and surrounded by a mass of fibrous tissue of cicatricial origin, was removed. The case suggests a method of dealing with some of the instances of old empyema with persistent sinus which resist all of the means usually employed for their cure.

Chronic Otitis.—Katz highly extols the use of chromic acid in this affection. He uses a three per cent. solution in those cases where the perforation is fairly large, and the exposed tympanic membrane much swollen or appearing tumefied; that is, where there is a tendency to formation of granulation tissue. The method is as follows:—The ear is carefully cleaned from all discharge by syringing, the use of Politzer's air douche, etc., and then dried. Then about six or eight drops are instilled into the ear with a pipette, forced into the middle ear by pressure on the tragus, and allowed to remain for two minutes, when they are syringed out with warm water injections. The outer ear is then filled with a cotton wool plug. This is done three or four times weekly, according to the action. There is usually seen after the third instillation a marked decrease, and in some a complete cessation, of the discharge, with considerable reduction of the swelling of the mucous membrane.

Symphyseotomy for resection of the male bladder has been done by Albarran in a case of epithelioma growing from the base of the bladder close to the neck. The pubic bones were drawn nearly two inches apart, and a large part of the bladder wall lying below the level of the pubes was excised. Good recovery.

Progress of Medical Science.

Gastric Manifestations Associated with Tuberculosis.—Dr. Potain, of the Charité Hospital, says the vomiting of phthisis is dependent upon three causes: 1. Subacute inflammation of the stomach, *i.e.*, subacute gastritis. 2. Dyspepsia due to general debility. 3. Constant or intermittent irritation of the vagus apart from any pathological change in the stomach itself. The symptoms usually make their first appearance in the stage of cavity formation in pulmonary tuberculosis. Patients who until then had suffered from moderate anorexia, now have complete loss of appetite. Digestion becomes sluggish, sometimes painful, but seldom accompanied by pyrosis or flatulency. The epigastric region is tender on pressure, tense, and frequently retracted. The tongue is dry, red, and glazed, and forms an excellent medium of culture for the parasite of thrush. There is seldom vomiting, but diarrhœa is a frequent accompaniment. The terminal gastritis of phthisical patients is not amenable to treatment, and is an indication that the end will not be long delayed. In the evolution of the gastric lesions, in the majority of cases nothing is found beyond a certain amount of hypertrophy of the mucous membrane of the stomach, the natural thickenings of which stand out with unnatural prominence, imparting to the surface of the membrane a peculiarly roughened appearance. It sometimes happens that these changes are limited to isolated portions of the mucous membrane, the remainder preserving a normal appearance. In more advanced cases, however, the surface of the thickened membrane becomes covered with polypoid vegetations resembling the formations described by Dr. Brissaud under the name of gastric polyadenomata. Lastly, when the condition has lasted for a long time, punctiform erosions are sometimes, though rarely, to be found scattered over the mucous surface, very few attaining the size of a pin's head. But these facts require to be confirmed by further investigation. From a histological point of view it is sufficient to say that the inflammation commences in the interglandular portions of the mucous membrane, while the secreting epithelium is only secondarily affected. It is, in fact, an intertubular gastritis extending from immediately underneath the epithelium toward the muscular coat of the stomach, which, however, never becomes involved in the inflammatory process.

Potain regards the morbid appearances found in the stomach as the result of suppuration in the pulmonary cavities, since they resemble closely the lesions found in convalescent typhoid patients. It is a question *sub judice* whether the primary cause of the lesions is introduced into the stomach by way of the expectoration or the blood. Although the gastritis of phthisis cannot be regarded as one of the symptoms of pulmonary tuberculosis, the same does not hold good in respect of the dyspepsia which marks the early stage of this affection, described by Marfan as the initial gastric syndroma. Whenever you are confronted with a patient suffering from cough and vomiting, which cannot be explained by the presence of any cardiac, vascular, or pulmonary lesion; whenever these symptoms are associated with emaciation and but little, if at all, influenced by appropriate treatment, you may anticipate the development after a variable period of time of the characteristic manifestations of pulmonary tuberculosis.

It is interesting to compare the gastric manifestations of incipient phthisis with the terminal gastritis associated with the advanced stage of this affection. The first of these early gastric symptoms is loss of appetite, but this anorexia is apt to assume various forms. In some cases the patient still relishes certain kinds of food, while in others there is complete anorexia. The patient complains of constant pain with a feeling of weight and distention in the region of the stomach. The gastralgia is worse after meals; the stomach is distended with gases, and the patient suffers from pyrosis and acid eructations,

symptoms that are very seldom observed in true tubercular gastritis. These symptoms become rapidly aggravated, and in a short time cough and vomiting, which are especially characteristic of this condition, are superadded. The ingestion of food at once excites a dry paroxysmal cough, which usually persists until the contents of the stomach are expelled. On the other hand, the cough ceases in most cases immediately vomiting takes place, so that it is obviously due to gastric irritation. Digestion excites cough, and cough causes vomiting; this cycle of events is absolutely characteristic of the phenomenon known as gastric cough. The physical signs of this gastropathy are also peculiar: the tongue remains smooth and moist, there is but little tenderness on pressure over the stomach, which can be easily explored and is usually dilated. Lastly, and this symptom is not devoid of a certain importance, the patients are usually constipated. The cause of the dyspepsia of early phthisis is not exactly known; it is evidently not due to the direct action of the tubercular virus on the stomach. In Potain's opinion these manifestations are more of the nature of neuro motor phenomena without any pathological change in the stomach itself. Atony of the muscular coat of the stomach can be compared with general loss of muscular strength and debility, and as a matter of fact they often exist concurrently. Gastric disturbances are of common occurrence both at the beginning and at the end of an attack of pulmonary tuberculosis; we have an initial dyspepsia and a terminal gastritis differing markedly from each other in character. They very seldom follow each other in the same patient, a further indication of the pathogenic differences which exist between them. There are numerous causes of vomiting in phthisis, but cases are also met with in which the stomach is perfectly normal, and the vomiting must be referred to irritation of the pneumogastric nerve.—*The North American Practitioner.*

Clinical Aspects of Fibroid Phthisis.—In an article on the varieties of pulmonary tuberculosis by Dr. J. K. Fowler, published in the *Practitioner*, this author gives the following *résumé* of fibroid tuberculosis: 1. Men are more often affected than women, and the period of onset is later than with the ordinary type. 2. The tendency to fibrosis is increased in those individuals whose lungs have been rendered vulnerable by inhaling irritating dust particles; the affection is therefore common among workers in various trades, *e.g.*, miners, knife-grinders, etc.; but it is by no means confined to such subjects. 3. There is often no family history of tuberculosis, but in one of the most marked examples known to the writer several brothers had suffered from tuberculous disease. 4. It is often accompanied by hæmoptysis, which may be profuse and recurrent. After the early attacks of hæmoptysis there may be no physical signs of disease within the lungs—their absence is of course no proof that such is the case. 5. Emphysema and bronchial asthma are frequently found in association with it. Catarrh may be present, but in some cases there is not the slightest tendency to that condition. 6. It is characterized by apyrexia which may persist almost throughout the case, even during periods of extension of the disease within the lungs. 7. The cough has not the paroxysmal character observed in "fibroid phthisis," and does not tend to produce vomiting. 8. There is an absence of night-sweats, and, generally speaking, of all acute symptoms. Dyspnœa is proportionate to the extent of infiltration and of emphysema, if present. 9. The sputa may be free from bacilli, or on the other hand they may always be present when looked for, a condition which is quite consistent with an absence of signs or symptoms of progressive disease. In a case known to the author they have been invariably found, when searched for, since the year 1882, during which period the individual has enjoyed almost uninterrupted good health. Microscopical examination of fibroid lesions in a stage of arrest may fail to show the presence of bacilli, although to the naked eye the appearances are unmistakably tuberculous. 10. The physical signs may consist of weak breath sounds and fine crackling râles mixed with catarrhal sounds. The râles may be widely distributed, but tend to spread from the apex toward the base. There may be no dulness; in its place there is often hyper-resonance from emphysema. 11. The wide area of the lungs over which the physical signs are present, in advanced cases, is often in marked contrast with the apparent well being of the individual. 12. Fibroid tuberculosis tends more than any other form of the disease to undergo arrest, and, short of that, to run a very prolonged course. Its recognition, therefore, becomes of great importance from the point of view of prognosis.

Operative Treatment for Dislocation of the Semilunar Cartilages.—Dr. Bruns reports four cases in which he operated successfully for dislocation of one of the semilunar cartilages of the knee, and from the literature of the subject collects others to the number of forty three. The dislocation affected the internal cartilage twenty-seven times out of the forty in which the point was specified, contrary to the opinion usually held. The dislocation is usually partial, and generally concerns the anterior portion; although the posterior end, or even the middle third of the cartilage, has been found torn from its attachments. A rarer form of injury is that in which the cartilage is wholly or partially torn across, or even crushed into a shapeless mass of fibres at one end. The dislocation follows almost always upon a traumatism; but in some cases a gradual loosening of the attachments seems to take place, a sort of spontaneous dislocation following. But Bruns emphatically denies that it is liable to follow over distention of the capsule, as in hydrops; in fact, he considers short and strong ligamentous structures as necessary for the displacement, which, in his opinion, occurs in forced rotation with the knee flexed. The diagnosis should be easy, by reason of the peculiar locking of the joint and the presence of the displaced meniscus close to the joint-cleft. In some cases the cartilage cannot be felt, but the joint-cleft is often found widened and more evident than normal, and somewhat tender. Treatment of the fresh dislocation would consist of immobilization for some four or six weeks; but even then it will not, as a rule, bring firm adhesions. Where the dislocation has become habitual, only operation can serve: and here it seems to matter little whether the displaced part of the cartilage be resected, or returned and sutured in place; for the functional results seem to be perfect in either method, even where the cases have been followed for years. Twenty-four cases were treated by extirpation, the rest by suture, all recovering.—*International Medical Magazine.*

Premature Labor in Accidental Hemorrhage.—The practitioner is ofttimes sorely puzzled to decide what course to pursue in cases of repeated accidental hemorrhage during pregnancy. In a case recently brought before the London Obstetric Society by Dr. Muir, premature labor was induced after a second smart attack of bleeding, with the delivery of a living fœtus. The placenta was found to be the seat of two distinct hemorrhages, of different dates, involving three-fifths of the entire organ and leaving only two-fifths to carry on the nutrition of the fœtus. It is evident that any further hemorrhage must infallibly have determined the death of the fœtus, and this Dr. Muir opines is an argument in favor of inducing premature labor and saving the life of the fœtus in cases where there has been a recurrence of the hemorrhage. The usual course, unless the amount of the bleeding is such as immediately to threaten life, is to keep the woman quiet and trust to luck. The result is in most instances spontaneous premature delivery, with an asphyxiated fœtus, a very unsatisfactory *denouement.* By so doing we shall be safeguarding the interests both of the mother and the child, for both are vitally interested in preventing a repetition of the morbid phenomenon.—*Medical Times.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, December 30, 1893.

TYPHOID FEVER IN CHICAGO.

CHICAGO may be considered pre-eminently the city of typhoid fever. From January 1, 1890, to November 1, 1893, there have been 5,087 deaths from this disease, or an average of 110 per month. This means that there have been from 25,000 to 30,000 cases. The epidemic began in 1889, with 453 deaths. The mortality increased until 1891 and 1892, when it reached nearly 2,000. It declined slightly in 1892, and has been somewhat less this year, but it is still very prevalent, there having been 712 deaths, and presumably over 4,000 cases, during the year ending September 30, 1893.

The above facts and their causes were recently presented in a direct and forcible way to the Chicago Medical Society by Dr. O. N. Huff, at one time member of the city Health Department.

Dr. Huff admits that there has been a disposition on the part of the city authorities to prevent the public having a full knowledge of the subject. Last winter, when he desired to present the matter to the Chicago Medical Society, he was actually forbidden to do so. The reason was partly the World's Fair, but also because it was on the eve of a municipal election and politics was in command.

A striking evidence of the defects in Chicago's sanitary administration is the absence of any trustworthy statistical records. Mr. Hart's statement, that the city afforded no sanitary records of great value, is confirmed by Dr. Huff. The low death-rate to which Chicago points as an excuse and justification is certainly misleading, even if it is numerically correct, for the city, according to Dr. Huff, has a very large proportion of people below the age of forty-five.

The causes of the prevalence of typhoid fever lie unquestionably in the water-supply. Dr. Huff gives facts and exhibits maps which seem to put this quite beyond doubt. The authorities of Chicago are, we believe, fully aware of this themselves, and are trying to mend matters by extending the source of the water-supply farther into the lake, and by trying to divert the sewage flow in another direction. We infer, however, that a large part of the city's water is obtained from cribs that are within the sewage line. It appears also to be very well proven that the administration of matters connected with the water-supply and sewage, has been in the past criminally negligent. The vicious system of a partisan government for spoils is responsible for this, as it has been for so much evil in municipal government elsewhere.

Dr. Huff's conclusions are worth presenting here. He says:

1st. That typhoid fever has been endemic in Chicago for at least four years.

2d. Since January 1, 1890, more than 5,000 lives have been destroyed by causes which modern medical science says are preventable.

3d. The cause of this frightful mortality can only be explained by a polluted drinking-water.

4th. The northern portion of the city has suffered a much greater death-rate than the rest of the city, to the extent of twice as great in 1891, and 2.34 greater per 10,000 in 1892.

5th. This variation in death-rate is not due to a difference in the character of the people, nor less desirable sanitary surroundings, but is produced by a more impure water-supply.

6th. This greater impurity of the water-supply was because north and northwest Chicago received a much greater portion of the water coming from the intake, 3,000 feet from shore.

7th. Some of these causes have been removed, and 1893 shows a marked decrease in death rate from typhoid fever, but Chicago is still having a much greater rate than any other large city, and with favorable conditions of rainfall, flood, wind, and current, Chicago is still in a position to have the epidemic renewed.

8th. That the whole system of drainage in the city is wrong, and "the sanitary history of Chicago is a history of makeshifts and expedients."

9th. Lake Michigan, in its natural state, is a water-supply "to satisfy the most captious," and it seems little less than criminal to pollute it with sewage from 1,500,000 people.

10th. We believe that a remedy is possible for the removal of the pestilential system, and that the question should be kept before the profession and the whole people until Chicago can have a pure lake water unpolluted by human and surface sewage.

THE WIDER AIMS OF THE NATIONAL BUREAU OF HEALTH.

IT is a little interesting and of great practical significance, that the new science of bacteriology, involving as it does the development and practice of most delicate and subtile methods of research, should, at the end of its first decade, have placed at the service of mankind means for its protection against disease which are not bound up within the limits of the laboratory, which require for use no intricate technical training, but which every health board can freely and easily employ, and every citizen in his usual walks of life beneficently foster.

The possibility of the wholesale prevention of disease by simple and easily comprehended methods, this is the great practical achievement which marks the medical science of to-day.

We can now see, with a certainty and definiteness never possible before, just how the average length of life may be raised, and an incalculable amount of suffering be spared, by the judicious and persistent use of the new protective resources against the ravages of infectious disease.

But in order to avail ourselves of these new resources, it is evident that the greatest good can be accomplished through those carefully organized official bodies of experts and specially trained men which constitute our boards of health.

The people are to be informed, advised, and helped in those details of sanitation and cleanliness by which alone the new promise may be realized, and the new knowledge is as speedily as possible to be made available for practical purposes by such organizations. By such organizations, and by them alone, can the safety of our people be secured in the face of threatened epidemic invasion.

But in a great confederation of States, like ours, something more than local health boards, however excellent these may be, is necessary, in order to stimulate, and harmonize, and help in the larger interests which our character as a nation involves.

This conviction has grown to be so fixed and strong among the medical men of the United States, that it is not surprising that a movement toward the establishment of a National Bureau of Health should have received the most wide-spread and practically unanimous support of physicians from all parts of the country.

The bill for the establishment of a National Bureau of Health, which was formulated by a committee of the New York Academy of Medicine, with advice and counsel from widely separated sources, and which is already in the hands of appropriate committees in both of the legislative bodies at Washington, seems to us admirably framed to accomplish the ends which the medical profession deems important, and at the same time is so moderate in its demands on the material resources of the country, and so wholly unpartisan and unsectional in its conception, that it does not seem possible that it shall encounter serious opposition or fail of abundant support.

The time is ripe for the enactment of such a measure, and it is safe to say that there is not a citizen of the United States who would not personally profit by the beneficent forces which the measure can bring into play.

While the administration of quarantine is provided for in considerable detail, it has apparently not seemed wise to the committee having the preparation of the bill in charge to propose at present any radical change in the system which has proved so efficient under the trying conditions of the season just past. The bill looks chiefly to the larger, and far more important, matter of the establishment and maintenance of such good sanitary conditions in all parts of the land as shall enable the people everywhere to cope, not only with those dramatic epidemic scourges which now and again may threaten them, but to control and largely suppress those infectious diseases which at all times are with us, and contribute so largely to suffering and to mortality among all classes of our people.

It is time that the United States should undertake to do for its citizens at least as much as it has done for its cattle; it is time that, as a nation, we should be ready to join intelligently and efficiently with other nations in the common fight for the suppression of communicable diseases; it is time that we should do what can be done to brighten the promise of the future by fostering research in the domain of preventive medicine.

NAIL-BITING AS AN EVIDENCE OF NERVOUS DISEASE.

Dr. Berillon, of Paris, who is chiefly known as a rather enthusiastic student of hypnotism, has published the results of what is announced to be a very elaborate study of nail-biting. He established the wide prevalence of the habit among French school-children. Thus, in a mixed school of the Department of l'Yonne the reports showed the following results:

	Number examined.	Nail-biters.
Boys	29	6
Girls	21	11
Total	50	17

The proportion of nail-biters here was for boys twenty per cent., and for girls fifty-two per cent.

In a boys' school at Seine-et-Marne the pupils were examined with respect to age with the following result:

	Number examined.	Nail-biters.
12 to 14 years	18	7
13 to 15 years	16	6
15 to 17 years	18	3
Total	52	16

From twelve to fourteen seems from this to be the age most susceptible to this habit. A like experiment with girls shows them to be even more susceptible at this age.

	Number examined.	Nail-biters.
10 to 13 years	80	27
12 to 15 years	75	21
15 to 16 years	52	13
16 to 17 years	10	2
Total	217	63

In all the schools where the children have been the objects of careful and attentive observation, the reports have agreed in pronouncing that pupils observed to have the habit are universally the poorest students; that if boys they are inclined to effeminacy, and if girls to slackness. In many there are marked defects of character and less sustained attention. The reports of writing-masters also declare their writing to be, while sometimes well formed, universally less legible and less regular, and the instructors in the Parisian schools for manual training have pronounced the habitual nail-biters hardest to teach and often unfit for technical education.

Among such pupils some have shown brilliant intellectual traits. Some are possessed of an astonishing memory, or show exceptional adaptability to certain arts or certain special studies. Of these "infant prodigies" a large proportion are found to be nail-biters. In such cases the exceptional brilliancy was of unnatural and ephemeral growth, and vanished at the age of fourteen or fifteen. The extraordinary development had compromised the normal evolution of the nervous system. In schools for children from six to eight years old those pupils cited by the matrons as most incorrigible, and upon whom fell the most constant discipline, were found, almost without exception, to be possessed of the habit.

In general, the nail-biters were found to be of decided inferiority, both from a point of view of intellectual development and from that of moral sensibility.

As to the cure, Berillon advocates strongly the grouping in classes of the children of the *lycées* who manifest

the habit, where they may be subjected to special discipline and hygienic treatment on the order of that which is employed in the English system of reformatory schools. He is opposed to the isolation of pupils who have the habit, as practised in England, on the ground that cure by this means is only transient. Regarding the habit as an indication of nervous degeneration, he would, in all cases, begin by a careful system of food and exercise, and thus try by every means to fortify the nervous system of the child. For curing the after-habit, which continues when the cause has been removed, he employs his own treatment, which is as follows: 1. To create a counter-irritant and thus to transform by outward excitation the unconscious act into a conscious one. 2. To create a counter-automatic impulse. 3. To strengthen the resolution of the child. He adds to these the treatment by suggestion while in hypnotic sleep.

THE DANGERS OF AUTOMATIC SPECIALISM.

In a recent number of the *Asclepiad* its talented author writes entertainingly on the healthy culture of the literary life. He utters a caution against narrow specialism in literary work, which is not inapplicable to specialism in medicine. "Philosophical historians have noted," he says, "how different ages present different, and, as it were, alternate pictures of mental and physical power. This age was one of genius, that of mediocrity; this of war, and that of peace; this of quiet inventive thought, that of inventive application," etc. As he well points out, these phases are all natural phenomena explained by well-known physiological data.

There is at the present time a tendency to introduce the mechanical principle into all departments of knowledge. Mental operations are trained to move with the precision of machinery. Parallel with this is the tendency to work in grooves. We call these latter specialties, and our present methods tend to lead up to an ideal perfection in one particular line of medical practice. This is to a certain extent most commendable, but, if carried too far, it saps vital nervous power. It makes the physician too dependent upon the instruments of precision which have been elaborated for the performance of his special line of work. He exalts the physical far too much above the physiological factor in diagnosis, and concentrating his attention too much upon one organ or set of organs, he forgets that they are but a part, and that the whole is greater than any one part possibly can be.

Especially is this true at the present time, when so many of the younger medical men are branching off into specialties without a sufficiently broad and deep foundation in general practice. Society membership, instrumental equipment, and facilities for clinical observation can never alone make a well rounded specialist. The ideas of diathesis in disease of hereditary tendencies and the like can be learned from books, but can never be apprehended in all their fulness except by long and patient watching at the bedside. The quick roads to apparent success which open so attractively, lead to limitation of view and of knowledge. Thought is repressed instead of stimulated. One becomes more and more dependent on others. "The perfect master in his own department is a helpless child so soon as he is out of his own narrow sphere."

The expansion of knowledge in every department of life has largely put an end to that ideal of "knowing something about everything, and everything about something." Only a few minds in a generation can hope to do this in anything like a systematic and efficient manner. The glory of modern specialism is that it has unravelled difficult questions in the etiology of disease, and its crowning work must lie in its ability to meet the demands which this new pathological inquiry makes with adequate therapeutic measures. To do this requires mental expansion in every direction, and not alone in any one.

News of the Week.

Dr. Samuel H. Olmstead, one of the old and most prominent physicians in Brooklyn, died at his home on December 23d. He had been ill but a short time, his death resulting from cerebral hemorrhage. Dr. Olmstead was born in New Haven, Conn., sixty years ago. He entered Yale College, and was graduated with high honors. At the breaking out of the war he entered the army as a surgeon, and was made a lieutenant-colonel. When the war ended he settled in South Brooklyn, where he built up a large and lucrative practice. He was an officer of the Loyal Legion and of the Kings County Medical Society, and was at one time connected with the Long Island College Hospital.

Only French "Doctors" on the Riviera.—Under a law recently put in force, only physicians graduated in France are allowed to use the title "Doctor" in that country. Consequently the English and American physicians on the Riviera have been requested to remove the title from their door-plates. They will be allowed to retain their practices, if they were certified health officers prior to the enactment of the law.

Popular for Her Debility.—*The Sun*, which is something of a fashionable purist as regards its English, publishes the following: "A certain physician had been called regularly every day to treat a woman who was very popular socially for general debility and exhaustion."

The Medical and Pharmaceutical Professions in Italy.—Official returns for 1892 give 19,120 as the number of general practitioners (*medico-chirurgi*) in the Italian peninsula, and 10,942 as the number of pharmacists provided with matriculation certificates and diplomas. Besides these there are 172 pharmacists possessing the inferior qualification known as the "bassa matricola," which has descended from the Pontifical government, and there are also 1,392 pharmacists' assistants. Out of 100,000 inhabitants there are, on an average, in Italy, 62 general practitioners (*medico-chirurgi*) and 36 matriculated pharmacists. Of the 19,120 general practitioners, the University of Naples is represented by 7,038 who have taken her degree. In the other continental states the general practitioners and pharmacists are much fewer in proportion to population than in Italy. Indeed, while Italy has 36 pharmacists per 100,000 of her inhabitants, the German Empire has but 13.3; Prussia, 11.9; Bavaria, 15.5; and Austria, 9.3.

Longevity and Ovariotomy.—Dr. Harris, of Philadelphia, has written to Sir Spencer Wells to inform him that there is living, and in excellent health, an unmar-

ried lady, eighty-one years of age, for whom the late Dr. John L. Atlee performed ovariotomy in June, 1843, more than fifty years ago. Dr. Harris asked if this case can be paralleled in England. This was Dr. Atlee's first ovariotomy. He had 80 cases; he operated on 7 in the year he became eighty-four years of age; he performed tracheotomy when nearly eighty-five, and died when nearly eighty-six years of age. We are indebted to Sir Spencer Wells for the interesting facts furnished by Dr. Harris.—*British Medical Journal.*

Dr. M. Landouzy has been appointed Professor of Internal Medicine and Therapeutics in the Paris Medical Faculty, in the room of Professor Hayem.

A New Surgical Institute for Paris.—Dr. Terrier, now at the Bichat Hospital, will replace Dr. Le Fort at the Pitié. Dr. Terrier, who is an enthusiastic advocate of antiseptic and aseptic surgery, has asked the medical faculty to give him a new service, organized entirely according to his ideas. His request has been granted, and the faculty will ask the Conseil Municipal to supply the funds required. There is a piece of unoccupied ground close to the hospital which will serve as the site for the new surgical institute.

There is said to be a good opening for a physician somewhere in North Carolina.

The Grip is undoubtedly developing rapidly in this and other cities. It does not seem to be so fatal, and in many cases it takes a nervous or muscular type. The patient suffers much from pains and prostration, but has few catarrhal symptoms.

Misuse of the Mails.—A few days ago one Hunter, an electric-pad-device man, was sentenced to the penitentiary by the United States Court of Cincinnati for a misuse of the United States mail, on the ground that his scheme was to defraud the people by selling a useless device.

The Medical Department of the Cincinnati University Degrees are said to be on sale and selling high in London, whereas none have ever been issued by that institution.

Cincinnati Physicians are getting very much waked up over the subject of quacks and illegal practitioners. The State legislature has repeatedly refused to enact a law protecting the public and the profession. It will not, however, be able to hold out much longer. Let the Cincinnati Academy organize a movement to reach the legislators before they assemble by means of local physicians, and they will succeed in getting what they want.

Patented and Proprietary Cosmetics.—When ladies wish a cosmetic, the wisest plan is to secure the advice of a physician who has paid some attention to a subject which concerns womankind so deeply. There are now several excellent treatises on cosmetics which deal with the matter legitimately. If the lady does not get the formula for a cosmetic from a responsible physician, it is safest for her to select a patented article, because Uncle Sam will not grant such rights for any article that is injurious. That is one reason why most makers of such preparations keep their composition secret and content themselves with trade-marks and labels. The protection accorded by law to a label or trade-mark may be perpetuated indefinitely by registration, whereas a patent can only be extended by act of Congress. The rules of the Patent Office reject all that is "injurious to the well-being or sound morals of society." A patented cosmetic is good to purchase because it has been analyzed by skilled Government chemists, and has stood the requisite test of novelty and usefulness. The same remarks apply to foods. A recent application for a patent on a liquid preparation for brightening the eyes, alleged to "intensify their color and brilliancy," was refused, as a matter of course, because it contained a harmful drug. One face-wash submitted not long ago revealed on examination the presence of corrosive sublimate as an ingredient.

Some Curious Dental Patents.—Dental surgeons have patented processes for imitating gold fillings in false teeth. This is done by burnishing gold-foil upon them in the manner commonly termed "fire gilding." Nobody would be likely to suspect that grinders showing plain signs of repair were artificial. Several applications have been made for patents for processes for setting diamonds in the teeth—the front teeth, of course—holes being drilled to receive the gems.

A Patent Aseptic Suit.—In the Patent Office at Washington is a disease-proof suit of clothes, intended to be worn by an operating surgeon. It is a comple suit of rubber armor, somewhat resembling a diver's dress. Being air-tight, no germs can enter it. Beneath each foot is a small bellows, which, being compressed by the action of walking, blows fresh air through the armor. The air enters and is filtered through a germ-proof diaphragm under the foot, passing upward and out through a similar diaphragm at the top of the head. The physician is enabled to see by two glass eye-pieces.

The Richmond City Hospital has been purchased by the College of Physicians and Surgeons of that city for $18,489.39.

It is Estimated that a Modern Medical College Plant, with facilities for imparting instruction to four hundred matriculates, would require an outlay of $150,000.—*Maryland Medical Journal.*

The Doctor as a Horse-killer.—Country doctors, even in regions where the roads are level and fairly well made, rival the street-car companies as destroyers of horses. It is a good horse that will serve a busy country doctor more than five or six years, and physicians that keep two horses to drive alternately, expect to buy a new one every five years. At the end of that time a doctor's horse is commonly fit only for the cart or plough. The speed has been driven out of it.—*The Sun.*

A Medical Tragedy.—An especially sad example of the dangers to which physicians are exposed is reported from Presburg, in Hungary. A physician, after visiting a patient with diphtheria, went home to change his clothes before continuing his calls. On entering the house his little son rushed up to him, and before the father could prevent it, had jumped upon him and kissed his face. Two days later the child was taken ill, and soon died of septic diphtheria. The father's reason gave way under the blow, and he died after a short illness attended by acute delirium, in which he constantly cried out, "I have killed my boy."

Society Reports.

SOCIETY OF MEDICAL JURISPRUDENCE.

Ninety-eighth Regular Meeting, December 11, 1893.

N. E. Brill, M.D., President, in the Chair.

Suicide and Evolution.—W. A. Shortt, Esq., read a paper upon this subject, treating of it in a way not without some interest to the practitioner of medicine. The theory which he offered in explanation of suicide—and he did not claim that it was yet more than a theory—was a somewhat novel one, namely, that it was an outcome of evolution which had resulted in the development of the higher centres at the expense of the lower, or instinct. He said that between the medical mind and the legal mind there was a deep gulf, which was especially manifest in the way in which they regarded the question of insanity, and, it might be added, suicide. The physician looked upon insanity as merely an abnormal mental condition growing out of a set of physical facts, such as disordered nutrition or diseased state of the nervous system. The lawyer, on the other hand, thought of insanity from the aspect of morals or ethics. The same difference of opinion existed between them in the view they took of suicide. The lawyer regarded it as a crime, and to be punished as such in case the criminal failed of his object; whereas the physician looked upon it as a form of insanity, as due to an abnormal physical condition, and applied treatment in accord with that view, disregarding the moral aspects of the act.

The author opposed the view that suicide was an indication of insanity. If this were true, he said, the number of suicides in a community would be in proportion to the number of the insane. Statistics showed that the reverse was true in most countries. In England the rate per million inhabitants was, of the insane, 3,190; of suicides, 75; in Scotland, of insane, 3,215; of suicides, 35, or a slight increase of insane and marked decrease of suicides; in Ireland, of insane, 3,676; of suicides, 10, being a still greater increase of insane and decrease of suicides. Neither did suicide and insanity correspond in periods of occurrence. For instance, insanity increased at puberty, whereas suicide remained low between the tenth and twentieth years.

Further evidence that suicide was not an indication of insanity, and was to some extent influenced by external circumstances, was shown by the fact that in the German army, consisting of picked men, supposed to be the strongest, the number of suicides was enormous. More doctors cut their throats than lawyers. The descendants of Abraham had always shown a repugnance to suicide.

Again, if suicide was due to insanity the causes ought to bear some proportion to one another in the two classes of cases. In insanity, a blow, a tumor, a pathological condition of some form in the nervous system existed much more frequently in proportion to some powerful moral shock than in suicide.

As bearing directly upon the question of evolution and suicide, the author said that animals never committed suicide. He doubted the case of the scorpion, and it was well known that in them instinct especially held sway. The lower the animal, the more instinctive were its actions. It was not until we came to man that volition and intellect became particularly manifest. In him, were it not for instinct, there would be nothing to restrain from the act of suicide, even under minor degrees of provocation. The growth of intelligence weakened all the instincts, including love for life, and it was the substitution of intelligent action for instinctive action which made suicide possible. The whole process of modern education and civilization tended to weaken instinct. Under the predominance of intellect occasions arose when a man might well question whether life was worth living; but where instinct held sway, he simply went on living. So far as his acquaintance extended he had found that all lawyers regarded only the external facts as influencing suicide, while all physicians considered alone the internal facts or physical condition of the individual. That both might play a part would be manifest from an extreme example: Smith's wife runs away, his daughter is ruined, he loses an only son, and fails in business. Under such circumstances is it necessary to suppose that he must be insane in order to commit suicide? Yet Jones, who is more under the influence of instinct, would go on living in spite of these, to Smith, overwhelming circumstances. The subjective factor must be strong, as well as the external circumstances, in order that one should commit suicide.

Statistics were again appealed to in contrasting the prevalence of crime with that of suicide. Crime implied the presence of instinct in full force, yet the rate of suicide was the reverse of that of homicide. That is, the degree of civilization where suicide was greatest was just the reverse of that where homicide prevailed. In the former, instinct was weaker or quiescent. In every portion of the world the extent of suicide corresponded with the extent of culture. This had also been true in ancient times. In Denmark, to day, where education was carried furthest, the proportion of suicides was greater than in any other part of the world with the exception of France, or, more particularly, Paris. In Arabia suicide was as rare as frost in Cairo. Culture was more widely distributed among men than among women, the latter were also more under the influence of instinct, and it had been observed that three men committed suicide to one woman.

Suicide was most common in May and June, the pleasantest, brightest, and most delightful months of the year, while in December and January, the most unpleasant months, the number of cases was at a minimum. The author would explain this oddity by the high state of activity of the instincts necessary to the prolongation of life during the severer months, and their low state of activity during the period of "spring fever." As soon as successful effort relaxed, instinct decreased. The fact that suicide was much more common in the day than at night pointed to the same conclusion.

Prevention.—The only treatment was obviously prophylaxis, and lay in exercise and such physical methods as would cultivate the instincts while obtaining an education. The student at present became only a thinking machine. All spontaneity was suppressed, the animal, the instinctive nature was squeezed out of him, and when, by the age of fifty, his partner robbed him, he took the shortest road out of the trouble.

Evolution, Devolution, Degradation, Suicide.—Dr. Frank Ferguson disclaimed to have given much thought to psychological questions, but he said that among the suicides on whom he had had occasion to make autopsies rickets was not uncommon; neither was dissipation to the point of being cast off by family and friends. Again, when a man had everything to the utmost range of his capacity of enjoying, and it all went away as by a breath of wind, the question of evolution was turned into one of devolution, of degradation, of a life which ceased to be one worth living—of suicide.

John A. Kamping, Esq., thought the view taken of suicide was, usually, a practical one by the lawyer, a theoretical one by the physician. The doctor's theory, carried to its legitimate conclusion, would make of every crime a mental disease, and, therefore, not a crime at all. In other words, that there was no such thing as moral obliquity. He drew his inferences entirely from a supposed relation of body and brain. The lawyer took the view of society generally, holding that to take life was murder, and the man who committed suicide was as much a murderer as he who killed his neighbor. Where, however, the life was taken because of mental disease moral responsibility was not present.

Narcotics, Intoxicants, and Suicide.—Dr. Quimby, of Jersey City, believed suicide to be due to poisoning the system with narcotics and stimulants of various forms,

including tobacco and especially alcohol. The few cases which he had seen were to be attributed to these causes. Dissipation ended with being cast out by family and society, by complete degradation, and a suicide's grave.

Do Animals Commit Suicide?—Dr. Robert S. Newton said there were countries in which suicide was regarded as proper. It was extolled in the religion of Brahma, and many of the people adopted it. Indeed, religious belief had much influence in the taking or not taking of one's own life. For instance, who would expect to hear that one who had committed suicide was a Presbyterian? He thought one reason why physicians said little about the moral aspect of the question was because of its close relation to that of religion, with which they felt that it was best not to meddle. The reader had said animals did not commit suicide. This was a mistake, for in Norway there was an animal which resembled in some respects both beaver and otter, and it had been observed that every nineteen years droves of them went to the water's edge, separated themselves into two groups, those of one group plunging into the water and deliberately committing suicide, making no attempt at rescue, notwithstanding their ability to swim. There was other evidence, too, that animals sometimes took their own lives.

Officers Elected—*President*, John S. Smith, Esq.; *Vice-President*, Edward F. Brush, M.D.; *Secretary*, W. H. Bates, M.D.; *Treasurer*, D. McLean Shaw, Esq.; *Corresponding Secretary*, Benjamin A. Jackson, Esq.; *Lawyers as Trustees*, William J. Lardner, Walter S. Logan, L. Van Allen; *Doctors as Trustees*, N. E. Brill, H. N. Heineman, Stephen A. Roof, H. Holbrook Curtis.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS—ELECTION OF DR. RUSSELL REYNOLDS—THE GENERAL MEDICAL COUNCIL—DIPLOMAS IN STATE MEDICINE—THE EDUCATION COMMITTEE—FALSE DISSEMINATED SCLEROSIS—MEDICO-CHIRURGICAL SOCIETY—FIBROSIS OF KIDNEY IN MALIGNANT ENDOCARDITIS—THE BRADSHAW LECTURE—SMALL-POX IN SALVATION ARMY SHELTERS—RETURN OF INFLUENZA—DEATH OF PROFESSOR TYNDALL.

London, December 9, 1893.

On Thursday last, December 5th, an extraordinary comitia of the Royal College of Physicians was held, and the successor of Sir Andrew Clark chosen. As I ventured to foreshadow, the choice has fallen on Dr. Russell Reynolds than whom no worthier could have been chosen. The only other serious competitor was Dr. Wilks, who had nearly as many votes as Dr. Reynolds, and would have been an equally good president. In accepting the office Dr. Reynolds alluded to the manner in which his predecessor had maintained the dignity of the presidency, and while modestly professing that he could not aspire to do as well, promised to spare no effort in the discharge of the honorable duties entrusted to him.

The General Medical Council concluded its session on Tuesday. Some other cases under the penal clauses were dealt with, and routine business transacted beyond the matters mentioned in my last. A great deal of time was spent over the regulations relating to diplomas in State Medicine, and it was determined to require that in all cases twelve months work should be devoted to study of the special subjects before admission to examination and after a qualification for practice has been obtained. Half the time must be spent in out-door work under a medical officer of health, and the other half in a laboratory.

No doubt such a practical course and a severe examination tends to increase the estimate of such diplomas, but it may be doubted whether the Council is right in devoting so much time to regulating a specialty of a few hundreds to the neglect of the interests of thousands of general practitioners.

The Council also had before it the reports of visitation of examinations and the Education Committee. Some of the examining boards sharply criticised, and it was amusing to notice that criticism was chiefly directed against those which have been considered hitherto the most severe. The Council was established to protect the public by securing that every practitioner should be duly qualified and registered. It spends too much time in listening to members' charges against rival corporations and the consequent *tu quoque*.

Nervous troubles after various infectious diseases are often made extensive in area and sometimes obscure. Among them false disseminated sclerosis has been several times recorded after the exanthemata, and a case following measles was carefully described by Dr. Dawson Williams at the last meeting of the Medical and Chirurgical Society, who thought that, excluding hemiplegia and atrophic muscular paralysis, the neuroses associated with measles might be classified as, 1, acute disseminated myelitis; 2, false disseminated sclerosis; 3, cases with some similar symptoms, but the most prominent symptom being inco-ordination; 4, cases of extensive ascending diffuse or disseminated paralysis resembling diphtherial paralysis. The nervous disorders that have been noticed in association with other diseases may be grouped in the same fashion, though the series cannot be completed for each disease. Vascular changes have been observed in the cord in acute disseminated sclerosis, and clinical evidence supports Westphal's suggestion that a slighter degree of the same changes might give rise to the so-called false variety. Temporary inco-ordination of the lower limbs after infectious diseases may perhaps be due to a similar state in milder form.

Dr. Ormerod remarked that this form of disorder had been reported by Dr. Foxwell as following rheumatic fever with hyperpyrexia. The condition, though unusual, presented a definite group of symptoms, viz., sudden onset early in the infectious disease, delirium, affection of speech, loss of limb power, and tendency to improve if the earlier stage were not fatal.

Dr. Penrose knew of a fatal case of influenza with nervous symptoms, in which scattered foci of diapedesis round vessels, and leucocytes in both the gray and white matter, had been found.

Dr. Beevor thought the sudden ouset, the unconsciousness, and fits pointed to the cerebrum rather than the cord, and that the spinal changes were probably descending lesions from the brain. Either a small hemorrhage into the cortex or thrombosis of the cortical veins would account for the symptoms. After infantile hemiplegia, inco-ordination of the arm occurred, and if both sides were affected the result would be symptoms such as had been described in the paper.

Other speakers drew attention to the peculiarity of the speech, described by Westphal as "squeezed out," and to the so-called chorea which follows canine distemper in which sclerotic lesions of the cord were described by Dr. Gowers some years ago.

At the same meeting Dr. W. A. Hollis read a paper on disseminated fibrosis of the kidney found in cases of malignant endocarditis, aortistis, and kindred diseases. His paper was illustrated with both macro and microscopic specimens as well as notes of cases, and he considered that he had shown that the disease of the kidney was probably dependent on that of the aorta, and that renal trouble is often associated with infective endocarditis. Dr. Herringham could not accept this view and saw nothing unusual in the specimens, although he admitted that renal pathology was "confused and confusing."

The Bradshaw Lecture this year was on "Some Diseases of the Thyroid Gland." It was entrusted to Professor Greenfield, and we expected to welcome him once again in London. Unhappily, he was prevented from

coming, but he had written his lecture and it was read for him by Dr. Sims Woodhead. As might have been expected, it was a very able exposition of the subject, abounding in pathological matter, and comparing the disease with myxœdema. There was an exhibition of lantern illustrations and microscopical preparations repeated the following day.

The law courts have decided that the Salvation Army shelters are not amenable to the Public Health Acts as to disinfection like common lodging-houses. The Medical Officers of Health cannot therefore interfere when, as lately happened, small-pox patients were entertained in a crowded "shelter." No wonder the disease spreads if such foci of infection are to be tolerated. All sanitarians are demanding speedy legislation. Meanwhile, if the Salvation "General" had common sense enough not to resist interference with his absolutism, he would solicit the aid of the health authorities in preventing his charitable shelters disseminating disease.

Influenza is now epidemic again both in London and in many parts of the country. The deaths directly due to the disease, which had been steadily rising from seven to thirty-six per week, in the previous five weeks, from the last figure suddenly jumped to seventy-five in the week. Of course, this represents a very large number of non-fatal cases. Further, there has been excessive mortality from respiratory diseases, many cases of which doubtless are due to the epidemic which has returned in most districts simultaneously, contrasting in this respect with its last appearance when it seemed to proceed more leisurely from place to place.

The death of Professor Tyndall on Monday last came as a shock on the scientific world and the public, although his health has for some time been precarious. The great scientist succumbed to a mistake. He was accustomed to take a dose of syrup of chloral at night, and a solution of magnesium sulphate in the morning. The two medicines stood side by side in similar bottles, and on Monday morning seven drachms of the syrup were given in mistake for the solution—another sad example of the carelessness with which even scientific minds regard the danger of confusing similar bottles of medicine. You will have received an account of the career and untimely decease of this great leader of science before this letter reaches you. The scientific members of our profession knew how to appreciate his work.

New Instruments.

IMMOBILIZATION VERSUS EXTENSION IN THE APPLICATION OF THE PLASTER-OF-PARIS JACKET.[1]

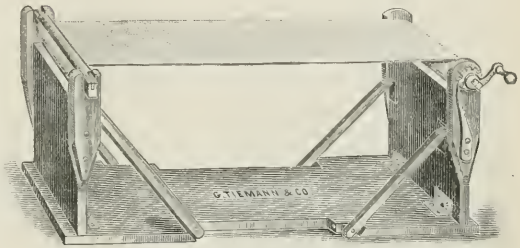
A New Hammock Apparatus.

By SAMUEL E. MILLIKEN, M.D.,

LECTURER ON SURGERY IN THE NEW YORK POLYCLINIC.

The first objection to extension being employed in the application of the plaster-of-Paris jacket for Pott's disease of the spine is that it is unnecessary because the subsequent good results obtained from its use depend solely upon the immobilization. No better evidence of this fact can be given than that the once much-lauded section jacket, with screws for extension, has been abandoned. Second, the method practised of suspending a patient by means of straps under the arms and around the chin and occiput, is tedious when applied to children owing to the fright occasioned. Third, all subjects which have been confined to bed from paraplegia or other complications are very liable to syncope while in the upright posture, and particularly so when the chin and occiput straps are employed to aid in the suspension.

To obtain the best fitting jacket the hammock in which the patient is placed should be tense so as to overcome the swaying, for which the apparatus here shown has been devised. A strip of ordinary muslin, six or eight inches broad, is put on the rollers, and by means of the handle can be made sufficiently tight. The hammock is three feet long, one foot broad, one foot high, and may be used for adults and children. The uprights are attached with hinges so as to make it conveniently portable when folded.



Advantages.—1. It is practicable in all cases of spinal caries.

2. Easiness of manufacture, as it is made of wood.

3. Voluntary muscular spasm is overcome.

4. The spine is kept in the nearest, a normal, position during the application.

5. The plaster can be made very light because the patient is allowed to remain undisturbed until complete hardening takes place.

Since the above illustration was made from a small model furnished me by Dr. Sidney Yankauer, resident in Mount Sinai Hospital, Messrs. Geo. Tiemann & Co. have made the apparatus very much lighter than the original.

Effect of Malpractice Charges and How to Avoid Them.—The Hon. David McAdam, Judge of the New York Superior Court, in a recent address on malpractice before the Society of Medical Jurisprudence, of New York, concluded with the following admirable advice: "Let the professional man live up to the requirements of his profession and observe its ethics. Let him keep up with every advance made in his science. Be careful in professional deportment, diligent in studies, exacting even as to details—putting whatever skill he has in all he undertakes—doing it well no matter what the case in hand may be, avoiding familiarity, drinking moderately of intoxicants, or what is better—not at all. Let him earn a reputation as a good, safe, reliable practitioner, and it will stand by him. It will make imputations of malpractice too improbable to be feared. They will fall like water upon a duck's back. Fortified positions are often impregnable. They are seldom attacked. Like the engineer upon a

steam engine, be ever on the alert for danger-signals and intelligent enough in vision to understand their meaning. Put down the brakes in time to halt in safety. If you have doubts consult some professional brother. Call him in to aid if prudent. A divided responsibility is sometimes desirable. Attack may be made on one, which the mere presence of two will at once avert. Take no unnecessary risks. Assume no needless responsibilities. Never make other people's troubles your own. Assist them by every professional means in your power. Use your best efforts. This is all you are called upon to do—all you can do. You can exercise no superhuman agency. You have no such power, and would be an impostor if you claimed to have. Neither science is an exact one. Neither is capable of assured and exact determination. The best men in the medical fraternity often disagree; so do the best judges upon the benches of the highest courts in the land. Lawyers and doctors should never encourage malpractice suits. They should be brought only in extreme cases, and then only against the unworthy. They seldom help the client, and are sure to injure the professional man, who, like Cæsar's wife, must be above suspicion. Professional men must have good names and keep them unsullied. Merchants may fail, and compromise at twenty-five cents on the dollar. The lawyer and doctor must pay one hundred cents every time, or go down deeper than any 'McGinty' ever read about in song or story. A merchant may do business in his wife's name. The lawyer and doctor must use their own, and if, for any reason, it is not usable, they are gone, bob-line and sinker, and 'none so poor as to do either reverence.' Then emulate the example of the men who have made 'Name' and earned 'Fame' in the two professions, and you will recall the days when it was a proud honor to be called 'Lawyer' or 'Doctor.'"

Bellevue Hospital, New York, had its origin in 1658, when the city had one thousand population. The first hospital was established on Broad, near Beaver Street, at the instance of Surgeon Jacob Hendrickson Varranger, of the Dutch West India Company. The building stood until 1680, when an "hospital of five houses" was erected. In 1697 an attempt was made to establish a poor-house hospital. Renewed attempts were made in this direction, which were finally successful in 1736, after a severe small-pox epidemic. The first physician of Bellevue was Dr. Jacob Van Beuren, who received a salary of $500, but had to supply medicines. As there were only six beds, the salary paid was, considering purchasing power, more than twenty times that paid under like conditions to-day.—*Medical Standard.*

Tannin and Theine in China and Indian Teas.—There is an important difference in the amount of tannin, but not of theine, in these China and Indian teas. The China teas contain from five to six per cent. of tannin, and the Indian teas an average of ten per cent. In both the theine amounts to practically the same—averaging 3.4 per cent. Distilled or softened water, or water to which carbonate of soda has been added, dissolves the tannin more rapidly, but effects no increase in the amount of theine dissolved; the practice of adding carbonate of soda to the water, therefore, is not to be recommended. Moderately hard water, used the moment it reaches boiling-point, effects just as rapid a solution of the valuable principle theine as distilled water, while the objectionable tannin is not so rapidly dissolved. China teas may safely be left to infuse for a longer period of time than Indian teas; for the former even fifteen minutes may be allowed without fear of dissolving an excess of tannin, but for the latter not longer than five, or at most seven, minutes is advisable. Tannin, of course, imparts astringency to tea; but this constituent is not wholly concerned in producing an infusion of the desirable body and strength, for the theine and tannin together amount to only one-fourth of the total extractive matter present, except in some instances of Indian teas, which are particularly and undesirably rich in tannin. The best results are obtained when the tea is powdered immediately before use. The flavor is then exquisite, complete extraction of the theine is insured, and, provided the infusion is allowed to stand for only five or seven minutes, a minimum of tannin is dissolved and no sacrifice of body of strength is perceptible. The remarks on distilled or softened water also apply here. The Indian tea used in this investigation was obtained by private purchase; the China teas were supplied by the Russian China Tea Company, which has been established with the avowed object of supplying Chinese plantation teas in the United Kingdom as imported into Russia.—*The Lancet.*

The Richardson Memorial of the Medical Department of Tulane University, at New Orleans, is a gratifying evidence of medical progress. It was dedicated November 4th with appropriate services. It is a commodious and imposing structure of four stories, containing in all seventy-two rooms, located on Canal Street, between Villere and Robertson Streets. The main lecture hall is fifty-five feet square and twenty-eight feet high, seating four hundred students in opera chairs. The building is the gift of Mrs. Ida A. Slocumb, in memory of her husband, Dr. T. G. Richardson, who devoted thirty-one years of his life as professor in the medical faculty of the school. The planning and erection of the building has been under the supervision of Professor Souchon. Judging from the reports the building is the outcome of the most diligent thought and study as to the construction of medical college buildings. May the school labor to send forth her graduates with an educational outfitting worthy of the unselfishness of the donor and of the excellent mechanism she has provided.—*Medical News.*

Anæsthetics, plea for gradual exhibition of, 815; remarks on the administration of, 573.
Anæsthetizer, a new, 573.
Analgesia by ethyl chloride, 695.
Ancient cerebral localization, 704.
Anderson, R. Harcourt, oxygen in cholera cursorily considered, 266.
Aneurism, aortic, in a boy, 349; diffuse popliteal, caused by an exostosis, 237; extirpation of, 58; new symptom of, 208; of femoral artery, 87; of mitral valve, 155; of subclavian, 310; of thoracic aorta, 281, 764; rare aortic, 154; relation of, to syphilis, 246; rupture of, in superior pancreatico-duodenalis with symptoms of biliary obstruction, 697; significant symptom of aortic, 719.
Angina pectoris, relief of, 28.
Angio-keratoma, 473.
Angio-lipoma, unique case of, 176.
Angioma of nasal septum, 409.
Animal extracts, new process for extraction of, 379; startling effect of, 512; therapeutic value of, 19.
Ankle, treatment of sprained, 239.
Ankle-joint, new method of operating at, for injuries of the foot, 634.
Anophthalmos, 186.
Anthrax, 700; bacilli in mud of a well, 734.
Anti-adulteration, extreme, 532.
Anti-diphtherine, 723.
Anti-rheumatic ring, 606.
Antipyrin in erythema nodosum, 765.
Antisepticism and Edinburgh surgery, 432, 499.
Antiseptics of the ancients, 337.
Anuria for eleven days, recovery, 586.
Aorta, cerebral hemorrhage associated with narrowing of, 716.
Aphasia, localizing value of, 220.
Aphonia, due to hypertrophic rhinitis, 684.
Apocodeine, 430.
Apoplexy, treatment of, 28.
Appendicitis, 58, 361, 700; and rational surgery, 63; a possible cause for, 242; discussion on treatment of, 539; best time to operate, 730; deductions from 110 laparotomies for, 443; hernia after operations for, 788; if seen early, 29; infectious, 443; is operation demanded in all cases of? 730; old, 156; post-partum, 14, 93; simulated by hæmatocele, 47; surgical treatment of, 340.
Appendix vermiformis, carcinoma of, 825; partial obliteration of, 91.
Arkansas State Lunatic Asylum, 365.
Army medical appointments, 334, 365; Medical Board, 366, 788; medical department of, 51; medical school at Washington, 467, 735; medical service, the, 179.
Arrow poison and microbes, 396.
Arsenic and cholera, 84.
Arterial venous nævi, excision in, 15.
Arterio-sclerosis, and rheumatism, 461; vertigo of, 191.
Arthritis, acute rheumatic, 182.
Arthrodesis, 686.
Ascites from cirrhosis, 699.
Aseptic suit, a patent, 844.
Ashmead, Albert S., immunizing for yellow fever, 508.
Aspergillus mycosis of the antrum, 436.
Asphyxia neonatorum, tongue traction in, 235.
Astasia-abasia, 808.
Asthma, 28, 506.
Ataxia, Friedrich's, 504; vaso-motor, 343.
Atropine as hæmostatic, 765.
Auditory canal, granite chip in, 425; syphilis of, 232.
Aural department in Mass. Infirmary, 150; reflex, due to impacted cerumen, 151; vertigo in children, 47.
Ayers, Edward A., new instrument for tightening ligatures, 414.
Ayres, Dr. S. C., 182.
Axis traction principle in obstetrics, 407.

B

Baby shows, practical view of, 156.
Bacillus coli communis, pathogenic properties of, 348.
Bacteria, culture of anærobic, 406; of respiratory passages, 361; of the surface, 634; prohibited in the U. S. Mails, 273.
Bacterial poisons, 492.
Bacteriological craze, 703.
Bacteriology, surgical, 337.
Bagdad, our consul at, 607; pharmacy, 608.
Baggage, disinfection (?) of, 263.
Baker, E. P., death of, 147.
Barber shop, dangers of, 319.
Bartine, O. H., death of, 307.
Baruch, Simon, logic as sentiment in therapeutics, 829; therapeutic reflections, 577.
Basedow's disease, 505.
Bates, W. H., new instruments for the removal of adenoid tissue, 318.
Battey, Dr. Robert, 628.
Battle-field aid, 753.
Baughman, J. A., complete denudation of testicle, 751.
Beach, Wooster, post-mortem childbirth, 223.
Becelaere, J. V., hemorrhoids, new feature in surgical treatment of, 139.
Bechterew succeeds Mierzejewski, 724.
Beck, Carl, regeneration of radius after its removal for osteo-sarcoma, 717.
Beer, imported, 432.
Bees and rheumatism, 20.
Beierhof, F., irrigation of the colon in infants, 446.
Bellevue Hospital, 848.

Benton, George W., death of, 306.
Bequests, recent, 563.
Beri-beri in Philadelphia, 658.
Berlin, clinical teaching at, 146; letter from, 187, 413, 603; typhoid fever at, 532.
Berry, V., purulent ophthalmia, imperforate hymen—a question of microbes, 352.
Bertillon, Dr. Jacques, 212.
Bigelow, H. R., dysmenorrhœa, 111, 447.
Biggs, Hermann M., is membranous croup contagious? 638.
Bill proposed to establish bureau of public health, 93, 253.
Birth in the coffin, 299.
Births, non-registry of, 318.
Bishop, a medical, 118.
Bismuth, phenates of, 479; subgallate in dyspepsia, 532.
Bladder, a nervous, 700; erysipelas of, 558, 700; lesion of, from distoma hematobia bilharzii, 826; tumors in, 700; valve at neck of, 113.
Blennorrhœa uro-genitalis in children, 300.
Bleyer, J. Mount, location of lost intubation-tube by electric searcher, 798.
Blindness, legislation for prevention of, 60; prevention of, from ophthalmia neonatorum, 88, 257; puerperal, 540.
Blood-corpuscles, red, have they a nucleus? 423; syphilitic changes in, 873.
Board of Health, more physicians, 500; resignation, 468; summer corps of, 51.
Boards of health have no power over city government, 788.
Bogue, R. G., death of, 787.
Bondurant, E. D., occurrence of indican in urine of insane patients, 806.
Bone, new devices for cutting, 634.
Bone cavities, treatment of, by copper amalgam filling, 392.
Book Notices:
Account of Bellevue Hospital, with a Catalogue of the Medical and Surgical Staff, from 1736 to 1894. Edited by Robert J. Carlisle, M.D., 821.
Anatomy of the Peritoneum, by Franklin Dexter, M.D., 119.
Atlas of Electric Cystoscopy, by Drs. Emil Burckhardt and E. Harry Fenwick, F.R.C.S., England, 692.
Brain Surgery, by M. Allen Starr, M.D., Ph.D., 821.

Textbook of Medicine for Students and Practitioners, by Adolf Strumpell, M.D. Second American edition, by Herman F. Vickery, M.D., and Philip Coombs Knapp, A.M., M.D., with editorial notes by Frederick C. Shattuck, M.D., 691.
Text-book of the Theory and Practice of Medicine, by American Teachers. Edited by William Pepper, M.D. Vol. I., 367.
Throat and Nose and their Diseases. With one hundred and twenty illustrations in color, and two hundred and thirty-five engravings, by Lennox Browne, F.R.C.S.E. Fourth edition, 691.
Treatment of Constitutional Syphilis. By Oswald Ziemsser, M.D., 822.
Traitement Chirurgical des Affections Inflammatoires et Néoplasiques de l'Utérus et de ses Annexes. Par le Professeur E. Doven, 783.
Year-book of Treatment for 1893, 367.
Boston City Hospital, medal for, 656; new medical school in, 366.
Bowlegs, manual treatment of, 661, 690.
Boylston prize for 1891, 147.
Brain disease, eye symptoms of, 498; surgery, 58; four cases of, 375; tapping lateral ventricles of, 340; weight of two sides of, 640.
Brand bath and typhoid, 764.
Branham, John W., death of, 334.
Brannan, J. W., quinsy and its treatment by early incision, 549; State and municipal control of infectious and contagious diseases, 833.
Brazilian medical staff, revolt of, 819.
Breast, epithelioma of, 825; operation for carcinoma of, 757.
Brewer, G. E., medical study in Edinburgh, 285.
Bright's disease, early diagnosis of, 558; influence of diet in chronic, 236.
British army surgeon, case of, 117.
British Medical Association, 245; section of medicine, 278; section of obstetrics and gynecology, 282, 310; section of surgery, 308.
Bromoform in whooping-cough, 28, 495.
Bronchial affections, 544; septicæmia in infants, 621.
Bronchiectasis, 361; coughing made easy in, 506; treatment of, 586.
Bronchitis, eucalyptol in chronic, 765.
Bronson, E. B., the treatment of itching, 487.
Brooklyn, a medical university for, 212.
Brotherly love, 272.
Brown, Ethel D., thyroid gland in myxœdema, 142; Everett J., persistent singultus and lavage of the stomach, 542.
Brown, J. S., a case of symphyseotomy, 582.
Brown, J. W., the latest electrocution, 222.
Brown, Price, abscess of larynx, 198.
Browne, Valentine, our school buildings, their construction, heating, ventilation, school hygiene, physical culture, 323.
Brownell, A. H., case of dysmenorrhœa, 235.
Bruce, Helen, death of, 20.
Brunswick, quarantine at, 212; yellow fever in, 531, 562.

Buboes, treatment of suppurating, 638.
Buck, A. H., strongly counter-irritant effects of the usual mastoid operation, 129.
Bucklin, C. A., the prevention of deafness, 198.
Buffalo, cholera infantum at, 212.
Bullitt, T. B., hair balls in stomach of ox, 93.
Burchard, T. H., unique case of angiolipoma, 176.
Bureau of Public Health, a, 241.
Buried alive, to be, 243.
Burneson, J. B., death of, 243.
Burns, iodoform in treatment of, 506.
Butts, H. Hoyle, new instrument for controlling tonsillar hemorrhage, 11.

C

Cactus grandiflorus in functional heart disorders, 764.
Cæsarean section, conservative, for placenta prævia, 787.
Caffeine, action of, 27; sulphate, 657.
Calculus, removal of impacted urethral, 719.
Caldwell, G. W., a new lachrymal probe, 318.
California, medical profession in, 79.
Calomel and gout, 590; antiseptic properties of, 427; in diphtheria, 736; in pseudo-membranous laryngitis, 572, 831.
Camphor with acetanilid, 28.
Canadian, a distinguished, 223; Medical Association, 503.
Canalicular knife, Weber's, 736.
Canary, an epileptic, 86.
Cancer, 249; and sarcoma inoculation for cure of, 178; of stomach, chlorate of soda in, 512; tissue, transplantation of, 187.
Cancerous inguinal glands, removal of, 362.
Capillary resistance and dichrotic notch, 348.
Carbolic acid, camphorated, 426.
Carbon dioxide and water, cutaneous excretion of, 428.
Carbonometer, a new, 414.
Carbuncle, 339.
Carcinoma, aniline products in, 812; of stomach, 698; uterine, 361.
Cardiac disease, causation of, 247.
Carotid, ligature of external, 527.
Carrier, A. E., management of eczema in childhood, 353.
Carroll, the late Dr. Alfred Ludlow, 596, 627.
Cartwright prize, 180.
Cataract, hard, removal of, by suction, 186; hook, 702; operations, blunt hook and hook knife for secondary, 575.
Catarrh, chronic nasal, treated by general practitioner, 89.
Cat and the caul, 468.
Catheter, an ancient, 534; male, 540.
Cats and diphtheria, 735.
Caucasian, the gregarious, 565.
Cautery, galvanic, 361.
Caverly, M. L., the non-registry of births, 318.
Cellulitis, pelvic, commonly secondary, 250.
Census of New York physicians, 788.
Centenarians, 20, 243, 595.
Cerebellar disease, optic neuritis in, 217; syphiloma, 585.
Cerebral hemiplegia congenital, 220; hemorrhage associated with aortic narrowing, 716; treatment of, 378; symptoms from indigestion in adults, 462; tumors, treatment of, 310.
Cerebrin, as curative of chorea, 591.
Cervical vertebræ dislocated, new method for reducing, 217.
Chambers Street Hospital, 62.
Chancre of tonsil, 768.
Charcot, the late professor, 351, 415.
Charcot's successor at Salpêtrière, 658.
Charities, bequests to, 432.
Charity patient got the better of the surgeon, 399.
Chess-memory, 639.
Cheesman, W. S., cholecystotomy, report of two cases, 225; Martin's operation on perineum, 109.
Chicago Medical College, 117; ship canal, 94; water-supply of, 663; water, not an ideal beverage, 213.
Childbirth post-mortem, 223.
Children, hernia in, 7; uro-genital blennorrhœa in, 300.
Chinese doctor makes a plea, 365; medical practice, 165.
Chisholm, Francis M., repeated and profuse hemorrhage subsequent to puncture of a meibomian cyst, 523.
Chloral, dangers of, 784; in cholera, 29.
Chlorate of soda in cancer of the stomach, 512.
Chloride of gold and sodium in nervousness, 28.
Chloroform, death from, 401; influence of, on labor, as shown by tachadynamometer, 590; in labor, therapeutic applications of, 371; in 1893, 88.
Chloroformization, technique of, 377.
Chlorosis, 699.
Cholecystenterostomy by Murphy's button, 801, 824.
Cholecystostomy, 225, 504, 801.
Cholera, 18, 403, 399; abating in Russia, 500; arsenic in, 84; chloral injections in, 29; danger of transmission of, by means of flies, 319; diagnosis of, 588; in Berlin, 562; in France, 52; its management in Hull, England, 569; Koch's diagnosis of, 85; oxygen in, 266; progress of, 146, 181, 210, 240, 277, 366; prophylaxis of, 39; prospects, 333; quarantine of, 60; report on, 147; therapeutics, 656.
Chorea, 765; cured by cerebrin, 591; hyoscyamine in, 699; in relation to rheumatism, 631; microbic origin of, 221; pathology and treatment, 631; related to rheumatism, 246; treatment of, 559.
Cholera infantum and its treatment, 85, 568; in Buffalo, 212.
Chorditis, tuberous, 608.
Choroid, sarcoma of, 184.
Cigar, one too many, 723.
Cimicifuga in seminal emissions, 29.
Cinchonamine, sulphate of, 384.
Cincinnati academy of medicine, 500; college of medicine, 118; physicians in politics, 690.
Circumcision, origin of, 607.
Cirrhosis, ascites from, 699.
City of magnificent hospitals, the, 303.
Civil Service Examinations, 562.
Claiborne, J. H., blunt hook and hook knife for secondary cataract operations, 575.
Clark, Sir Andrew, illness of, 594; death of, 628; will of, 818.
Cleft palate, anterior, new operation for, 58.
Cleveland, medical colleges of, 432.
Club-foot, bone operations for the correction of, 661; double lever stretching apparatus for, 659.
Cocaine, in abdominal surgery, 749; in gynecology, 53; intoxication, prevention of, 495; phenyl, 607; use of, as local anæsthetic, 203.
Code, revision of, 49.
Codeine poisoning, 81, 446.
Cœlia and lapara, 364.
Cœliotomy vs. laparotomy, 566; after-treatment of, 55, 441.
Cold bath in country practice, 298; in tetanus, 28.
Colds, gelsemium in, 27.
Cole, Carter S., depressed fracture of the skull, 777.
Coleman, P. C., persistent singultus relieved by lavage of stomach, 426.
Coley, W. B., operative treatment of hernia in children, 7.
College of Physicians and Surgeons, New York Alumni Association, prize of, 756; at Richmond, Va., 627.
Collins, Dr. Joseph, 627.
Collodion in hemorrhoids, 466.
Colon, irrigation of, in infants, 329, 446.
Colorado Medical Library Association, 468.
Colored race, insanity in, 761.
Colotomy, inguinal, 635.
Colt, Edwin N., death of, 401.
Columbia College, 19; medical department, 147.
Coma, after operation for epilepsy, 588.
Comedones, treatment of, 765.
Communion cup, done away with, 50.
Concannon, James J., complete burial of a ring beneath the skin of the finger, 584.
Conception, does gonorrhœa prevent? 757; during the puerperal period, 640.
Conference of New York State hospital superintendents with State commissioners in lunacy, 627.
Congress of American Physicians and Surgeons, 212.
Conjunctival membrane, transplantation from eye of rabbit to human subject, 375.
Connecticut, medical legislation in, 85; practice of medicine in, 128.
Constipation, an excellent pill for, 506; aperient for occasional, 506; habitual, of neurotic subjects, 699; simple remedies for, 506.
Consumption, 699; key-notes to the treatment of, 651; official declaration of contagiousness of, 656, 754; to prevent, 533.
Contagion from kissing, 333.
Contagious disease, clinical instruction in, 401; weekly statement, 31, 64, 94, 128, 160, 191, 224, 287, 319, 383, 415, 448, 479, 511, 531, 543, 575, 605, 638, 672, 703, 734, 767, 799, 831, 847.
Continued extension, some of the uses of, 659.
Cool bath in typhoid, 287.
Cooper, Henry C., death of, 213.
Co-ordination, mental and organic, 378.
Carlett, W. T., malignant growths of the skin, particularly of the face, 299.
Correction, a, 399.
Corset, a paper, 661.
Coryza, recent, 506; salicylic acid in, 288, 834.
Coroner system, 666, 695; condemned, 468; investigating the, 401, 430; to change, 725.
Cosmetics, 471; patented and proprietary, 844.
Cot, a surgical, 661.
Cotton swab, a new, for obtaining fluids, 155.
Cough, glycerine for, 7.
Cow's milk, modified for infant feeding, 794.
Cox, F. A., death of, 212.
Cranioclast, embryotome, and cephalotribe combined, 759.
Cremation, millennial of, 241.
Creosolat, 700.
Creosote in inoperable cases of surgical kidney, 681; subcutaneously, 829.
Crocker, H. Radcliffe, dermatology in its practical relations to general medicine, 573.
Cross, E. B., practical value of baby-shows, 156.
Cross-saddle riding for women, 626.
Crothers, T. D., medical care and treatment of inebriety, 135.
Croup, 699.
Cruelty to Animals, Society for Prevention of, 754.
Culbertson, Dr. J. C., 182.
Cushing, W. R., typhoid fever, its de novo origin, 507.
Cutaneous affections, static electricity in, 649.
Cycles, anti-vaccination, 146.
Cycling, 95.
Cyst, congenital, of orbit, 186.
Cysticercus cellulosæ, 358.
Cystitis, blennorrhagic, 506; methyl violet in, 505.
Cystoscopy, exploratory incision preferable to, 534.
Czerny, Professor, 366.

D

Daggett, B. H., a new holder for Sims' speculum, 509.

Inoculation treatment, hopeful of, 792.
International Medical Congress, 147, 180, 658; eleventh, 723; twelfth, 787.
Insane, alcohol for, 505; and the general practitioner, 504; asylum commitments, 244; care of, in Maryland, 761; dangers to State hospitals for, 752; detention hospitals for, 215; duty of the State to, 511; indican in urine of, 806; New York's laws for, 820; origin of the non-restraint system in the treatment of, 683; temperature in general paralysis of, 216; tobacco for, 594; voluntary commitment of, to asylums, 538.
Insanity following infectious diseases, 585; of women, Indian hemp in, 700; universal increase of, 480.
Insect powder causing inflammation of upper air-passages, 504.
Insolation, 74.
Insomnia parties, 500.
Instruments of precision, calendar of discovery of, 432.
Intestinal anastomosis, 789; anastomosis without plates, 57; obstruction, 91; following abdominal section, 632; from twisting of bowel, 764; in children, 656; non-operative treatment of, 312; laparotomy in acute, 56; surgical treatment of, 312.
Intestine, determination of stomach end in divided, 93; gangrenous, treatment of, 45; obstruction of large, by typhlotomy, 589.
Intra-uterine poisoning, alleged, 606.
Intubation, indications for, 361; report of 70 cases, 673; location of lost tube by electrical searcher, 798.
Iodide of potassium, mode of giving, 27; pills, 160.
Iodine trichloride, hypodermatically in puerperal septicæmia, 723.
Iodism, acute, 207.
Iodoform in lupus, 239; in treatment of burns, 506; odor of, avoided, 95.
Iowa, physician's liability for selling liquors in, 820; Public Health Association, 212; State medical examiners, 148.
Ipecacuanha, effects of, on uterus, 28; in hæmatemesis, 607.
Irrigator, a new intra-uterine, 575.
Iris, traumatic dislocation of, under unbroken conjunctiva, 186; tubercular tumor of, 184.
Iritis, rheumatic, 700.
Iron, best preparations of, 49.
Isolation, in country districts, 762.
Italy, the medical and pharmaceutical professions in, 843.
Italian surgeons, 532.
Itch, increase of, 433.
Itching, treatment of, 481.
Izal, non-poisonous disinfectant, 147.

J

Jackson, Edward, the use of cocaine to produce anæsthesia of skin and tissues beneath, 203.
Jacobi, tribute to Dr. Abraham, 787.
Jamaica, climate of, 434.
Japan, physicians in, 704.
Japanese dentistry, 735.
Jarman, Dr. George W., 595.
Jaundice from mental emotion, 587; in syphilis, 237; obstructive, 801.
Jaw, dislocation of lower, new method of reducing, 527.
Jay, J. G., antiseptic needle-holder, 159.
Jeffrey, A., procidentia uteri in a pregnant woman. 81.
Jenks, E. W., the limits and requirements of gynecology, 617.
Jenks, W. F., memorial prize, 307.
Johns Hopkins' medical school, 20; medical college—opening of, 532; university, 243.
Joint disease, mental condition of patient as element in treatment of, 659.
Jones, S. S., nitrate of silver solution in gastric ulcer, 31.
Judson, A. B., practical points in the treatment of hip disease, 545.

K

Kahler, Professor, successor of, 147.
Kansas City Medical College, 562.
Kansas way, the, 182.
Keating, Dr. John M., death of, 724.
Keeleyites at war, 399.
Keiser, Elmer E., infant umbilical hemorrhage, 424.
Kennedy, James, a study of factors concerned in reconversion of peptone into albumin, 43.
Kentucky, new law regulating medical practice in, 448; school of medicine, 118.
Keratitis, a disease of the poor, 764.
Keynotes to the treatment of consumption, 651.
Kidney, about the condition of the other, 534; calculus in substance of, 763; chronic contracted, mystery of, 331; creosote in inoperable cases of, 687; displacement of, 504; does it move? 50; movable with hydro-nephrosis, 586; single tubercular, 90; small cirrhotic, 91.
Kimball, R. B., case of myxœdema with unusual features and rapid recovery, 814.
Kinnicutt, F. P., myxœdema and its treatment; functions of thyroid gland, 449.
Kleptomania in the consulting-room, 639.
Knee, arthritis of, 153.
Knee jerk, 591.
Knee-joint disease, etiology of the deformities of, 660.
Knee-splint, a simple and effective, 661; a new, 660.
Knock-knees, manual, treatment of, 661.
Koch, a new work by, 787.
Koehler, F. W., the prevention of true and false diphtheria, 421.
Kohn, S., the internal administration of calomel in pseudo-membranous laryngitis, 229.
Kraske's operation, 635.
Kubin, W. E., modified Parkinson ether inhaler, 478.
Kyphosis, bicycle, 116.

L

Labor, case of painless, 815; influence of chloroform on, as shown by trachadynamometer, 590; mechanism of, 370; operative interference during second stage of, 517.
Lachenour, Dr. H. D., death of, 627.
Lagrippe in Alaska, 628.
Laminectomy, case of, 760.
Landes, Leonard, the need of a National Board of Health, 637; treatment of diphtheria by eucalyptus, 783; what a National Board of Health might do, 383.
Lanphear, Emory, abdominal hysterectomy, 352; abdominal hysterectomy with clamps, a rapid and safe way of removing the uterus, 4
Laparotomy in rectal stricture of puerperal origin, 264; vs. colliotomy, 561.
Larkin, T. J., a case of painless labor, 815.
Laryngitis, calomel in pseudo membranous, 572; chronic treatment of certain cases of, 345; pseudo-membranous, internal administration of calomel in, 229; pulsus paradoxus in, 144.
Larynx, abscess of, 196; chronic congestion of, 764; tuberculosis of, 765; tubercular ulceration of, 437.
Lateral curvature, apparatus for recording in, 661; by pressure correction and gymnastics, 659; case of, 659; sinus, thrombosis of, 150.
Lavage of stomach for persistent singultus, 426, 543; in toxic poisoning, 299; of whole intestinal tract, 594.
Law, James, cholera, prophylaxis of, 39.
Laziness, pathology of, 269.
Lead colic, antipyrin in, 27; olive-oil for, 589.
Lee, Charles Carroll, memorial of, 597.
Lens dislocated with maintenance of useful vision, 185.
Lepers, how shall they be cared for? 664.

Leprosy, alleged contagiousness of, 236; and tuberculosis, 502; decreasing, 690; in Great Britain, 113; investigation of, 212; is it contagious? 502; nerve-lesions of, 653; question of communicability of, 705; recrudescence of, 286.
Levick, James J., death of, 84.
Leviseur, Fred. J., exclusion of immigrants because of favus, 317.
Lewis, Bransford, rôle of posterior urethra in chronic urethritis, 132.
Lichen planus, 506.
Life, 465.
Life insurance, medical ethics in, 191; medical recommendations, 511.
Ligation, homologous, of divided arteries, 377.
Ligatures, new instrument for tightening, 414.
Light in sick-room, 27.
Lightning, death by, in France, 432.
Lilienthal, Howard, hippuric and benzoic acids, 543.
Linn, S. H., specialties in medicine and surgery, 477.
Linthicum, G. M., syphilis of auditory canal, 232.
Lipoma of tongue, 385.
Literary workers, diet for, 562.
Lithium salicylate in rheumatism, 700.
Lithopædion removed by laparotomy, 209.
Lithotomy, abandonment of, 594; in women, 284; perineal, 655.
Liver, abscess of, 91, 206; operation, recovery, 175; sudden death from, 15; and pancreas accessory, 152; carcinoma of, 152.
Liverpool, inspection of emigrants at, 192.
Lochia, the, 239; retention of, 463.
London, Academy of Medicine for, 181.
London Hospital fund, what it has accomplished, 146.
London, letter from, 29, 61, 92, 123, 187, 222, 252, 315, 381, 411, 475, 507, 542, 570, 602, 636, 669, 701, 733, 766, 795, 846; scarlet fever still prevalent in, 224.
Longevity and ovariotomy, 843
Lookout Mountain, Tenn., as a health-resort, 491.
Luck, L. N., death of, 756.
Lunatics, use of tobacco by, 724.
Lung, gumma of, 522.
Lupus, 765; erythematosus, 505; as imitator of various forms of dermatitis, 472; iodoform and nitrate of silver in, 239.
Luria, George A., is there a real necessity for a National Board of Health? 447.
Lusk, Z. J., codeine poisoning, 446.
Lympho-sarcoma, 236; of retro peritoneal glands, 153.
Lyman, H. M., a possible explanation of the Victoria disaster, 317; Glenwood Springs, Col., 746.

M

McCann, James, death of, 20.
McGill university, 64.
McGillicuddy, J. T., operative interference during the second stage of labor, 577.
McIntosh, T. M., complete inversion of uterus, treated by abdominal section, 176.
Mackenzie, Sir Morell, life of, 213.
Madrid academy of medicine prizes, 564.
Magill, William S., a new and rapid method of anæsthesia, 524.
Magnet, permanent, for removing foreign bodies from cornea, 186; removing steel from vitreous, 186.
Maisch, Charles O., a case of stramonium intoxication. 525.
Makejew, A. M., 86.
Malacine, 799.
Malaria, etiology of, 112; forms of, 341.
Malarial influence, how to overcome, 720.
Male nurse, the, 429.
Malpractice, how to avoid charges of, 847; suit for, 658.
Man, a simple minded, 239; great enemies of, 145; height of, 239.
Manhattan Hospital, 756
Mania, homicidal, 44; threatened, pilocarpine in, 64.
Manitoba medical college, 690.
Manley, Thomas H., lesions of the spinal cord with and without fracture, 554.
Maritime policy, general and efficacious international, 474.
Martin's operation on perineum, 109.
Maryland, care of insane in, 761; medical and chirurgical faculty of, 760; medical society of university of, 658; State medical society, 658.
Mask, Ring's ocular, 575.
Massey, G. Betton, a plea for the early diagnosis and prompt electrical treatment of fibroid growths of the uterus, 682.
Massage, internal, in nose and throat disease, 97.
Mastoid operation, counter-irritant effects of, 129, 149; suppuration, 361.
Masturbation, diagnosis of, 123.
Maternity hospitals, 407.
Mattison, J. B., modern and humane treatment of morphine disease, 804.
Maxilla, tumors of superior, 760.
Maxwell, E. A., death of, 466, 531, 544.
Mayer, Emil, a new pharyngeal curette, 415.
Mayer, Oscar J., treatment of bone cavities by filling with copper amalgam, 392.
Measles, inoculation of, 19.
Meat eating and bad temper, 128.
Meatus, contracted, 361.
Mechanism, a new traction for hip splints, 659.
Medal worth having, 755.
Medical boards and hospital managers, 688.
Medical charities, abuse of, 532.
Medical college, a new, 595.
Medical college, story of a, 430.
Medical congresses, figure-heads in programmes of, 608.
Medical diplomas, sale of, 147.
Medical distinction, a, 563.
Medical editors, responsibility of, 431.
Medical education in England and America, 528.
Medical education in the United States, 366; progress in, 146.
Medical heroism, touching tribute to, 466.
Medical jurisprudence, congress on, 399.
Medical journals, the number of, 432.
Medical life, conduct of, 608.
Medical men as witnesses, 211; club for, 597; new opening for, 95.
Medical missionaries, work of, 605.
Medical population, movement of, in New York, 49
Medical practice act in New York, 672, 774.
Medical profession in France, 270; part taken by, in the discovery of America, 404, 478; of New York, tribute to, 722.
Medical science, progress of, 306.
Medical Society of the State of New York, 399.
Medical students, to, 499.
Medical tragedy, a, 844.
Medicine, modern experimental, 758; study of, in order to become a novelist, 563.
Medico legal contest, a curious, 244.
Meibomian cyst, repeated and profuse hemorrhage subsequent to puncture of, 524.
Meierhof, Edward L., note on the determination of refraction and accommodation, 395.
Membranous croup, is it contagious? 638.
Memoranda, clinical, 21; surgical and pathological, 538.
Menière's disease, surgical treatment of, 150.
Meningitis, cerebro-spinal, 152, 153; cerebro-spinal with hemiglobinuria, 349.
Menstruation, mineral baths during normal and pathological, 300.
Mental disturbances, etiology of, after pelvic operations in women, 442.
Mercury and iodide, curative and preventive action, 653.
Mercurial flannels in treatment of syphilis, 505.
Mercurial ointment, simple application of, in syphilis, 590.
Mercuric iodide in tic douloureux, 27.
Mesentery, cyst of, 698.
Methyl chloride in sciatica, 699; violet in cystitis, 505
Methylene blue in diphtheria, 267.
Mettler, Dr. L. Harrison, 531; on the treatment of seminal incontinence, 457.
Microbes, action of electricity on, 756; and arrow poison, 396; a question of, 352; in dust, 304; on postal cards, 469; new stain for those not reacting to Gram's method, 461.
Microcidine, 765.
Middle-ear discharge arrested by removal of pharyngeal adenoids, 235; disease, autopsies in two cases, 149.
Midwifery, to regulate, 407.
Migraine, ophthalmic, 622.
Mika's operation, 532
Millions for our hospitals, 593.
Milk laboratories, 552; modified, 552; pure for babies, 530; sterilized, new apparatus for, 140.
Millard, Henry B., death of, 401.
Miller, J. F., death of, 243.
Milliken, Samuel E., immobilization *vs.* suspension in application of plaster jacket, 847.
Mind-readers, offer to, 86.
Miscarriage, recovery of damages for, 636.
Mississippi Valley Medical Association, 181, 630.
Mitral affections, morphine in, 764; valve, aneurism of, 154.
Modern Samsons, 115.
Modern surgeon, the crowning glory of, 432.
Molesworth, W., a new carbonometer, 414.
Monell, S. H., static electricity in cutaneous affections, 649.
Montefiore Hospital, 19.
Moore, J. A., case of hypospadia cryptorchidism and ectopia cardis, 177.
Moore, James E., treatment of fractures involving elbow-joint, 583.
Moore, C. C., case of abscess of liver, 206.
Morphine disease, modern and humane treatment of, 380, 804; in mitral affections, 764; poisoning, stretching sphincter ani in, 27.
Morphiomania, increase of, in Paris, 365.
Morrill, Dr Jesse Lee, 500, 531.
Morris, R. T., post-partum appendicitis, 93.
Mortality from overcrowding, 768.
Morton, H. McI., an instrument for the rhythmical exercise of the ocular muscles, the phorotone, 508.
Morvan's disease, 113.
Moser, William, cysticercus cellulosæ, 358.
Moser, William, have the red blood-corpuscles a nucleus? 423.
Muñiz, Dr. Manuel Antonio, 787.
Mumps, causing deafness, 268.
Murphy, Dr. J. B., 788.
Murray, Alan B., a new intra uterine irrigator, 575.
Mutter lectures, 563.
Mydriatic, a new, 208.
Myoma uteri, 665; galvanism in, 666.
Myopia among college students, 788.
Myositis ossificans, case of, 348.
Myxœdema, 174, 221, 279; and thyroid extract, 725; case of, with unusual features and rapid recovery, 814; thyroid gland in, 142; treatment of, 449.
Myxoma of nose, 698.
Myxo-sarcoma of nasal cavity, 410.

N

Nævi, arterial venous, treated by excision, 15.
Nail-biting among children, 396; as an evidence of nervous disease, 842.
Nails, congenital absence of, 269.
Nammack, Charles E., cerebellar syphiloma, 585; cerebral hemorrhage associated with narrowing of the aorta, 716; imperforate hymen, 81.
Naphthol as vermifuge, 28.
Napoleon the First's medical advisers, 499.
Nasal cavity, myxo-sarcoma of, 410.
Nasal reflexes, forms of, 344.
Nasal septum, angioma of, 409; electrolysis of, 161
Naso-pharynx, sarcoma of, 410.
National Health Bill, is there a necessity for, 447.
National Board of Health, advisability of, 372; need of, 637.

National Bureau of Health, 83; opinions concerning, 180; the wider aims of the, 841; what it might do, 383.
National Guard of New York State, 690.
Naval Hospital, improvement of, 334.
Naval Medical Service, suggestions for improvement of, 656.
Naval post-graduate school at Brooklyn, 433.
Neck, tumors of, 87.
Needle, canaliculus probe, 702.
Needle-holder, antiseptic, 159
Negro physicians, organ of, 724.
Nephrectomy, or nephrotomy, 87; in hydronephrosis, 766.
Nephrotomy and nephrectomy, 534.
Nerve-troubles, hydrotherapy in all forms of chronic, 505.
Nerves, ganglia ted, diseases of, 380.
Nervous disease, nail biting as an evidence of, 842; pathology of, 82; treatment of, in sanitariums, 380
Neuralgia, 505, 506; treatment of, 28; aconitine in trigeminal, 27.
Neurasthenia, spinal, 220, 321.
Neurectomy, intra-cranial for neuralgia, 731; in spasmodic torticollis, 735.
Neurologists, breeding place for, 831.
Newcomb, James E., electrolysis in certain morbid conditions of nasal septum, 161.
New Jersey, health of, 59.
New Jersey Medical Society, 59.
New Jersey State Board of Examiners, annual report of, 531.
New Medical School, a, 306.
New remedies, a decade of, 704; notes on, 735.
New warships, provision for sick and wounded on, 115.
Night air, 480.
Niles, H. D., gastrostomy in stricture of the œsophagus, 714.

Œsophagotomy, 361, 829.
Œsophagus, gastrostomy in stricture of, 714.
Œlema, malignant, new anærobic bacillus of, 405.
Ohio State Association of Railway Surgeons, 500.
Ohio State Asylum for Epilepsy, 656.
Oil for subcutaneous injection of remedies, 506.
Olive-oil for lead colic, 589.
Omaha Medical College, new building for, 724
Omentum, hypertrophy of, in hernia, 733.
Omission, a curious, 656.
Onychophagy, 367.
Operation wounds, method of closing, by sliding skin flaps, 717, 824.
Operations, multiple, at one sitting, 828.
Ophthalmia, contagious, 121; neonatorum, disastrous case of, 184; neonatorum, prevention of blindness from, 257; purulent, 332; purulent, specific microbic cause of, 79
Ophthalmic solutions, ready sterilization of, 116.
Ophthalmoscope, history of discovery of, 769.
Opium and bromide for epilepsy, 590; users, insurance of, 734.
Optic thalamus, tumor of, 220.
Oral region, correction of deformities of, 644.
Orbit, congenital cyst of, 186.
Orchidopexy, 813.
Orchitis, gonorrhœal, 361.
O'Rorke, the late Dr. James, 213.
Ossicles, comparative anatomy of, 149.
Osteo-arthritis, 496; joints in, 589; of knee, mechanical treatment of, 373.
Osteo-sarcoma, simulating tubercular hip disease, 659
Os uteri, rapid manual dilatation of, 406.
Otalgia, 506.
Otitis, chronic, 839; nervous, 764.
Otto, the insane king of Bavaria, 214.
Ovarian cysts, drainage of, 441.
Ovarian tumors, diagnosis of supposed, 757.
Ovaries, rudimentary, 790.
Ovariotomy in the aged, 632; post partum, 314
Overcrowding, mortality from, 768; a sure check to, 565.
Overholser, M. P., tuberculosis, 291.
Oxygen in cholera, 266.
Oysters raw, and typhoid, 754.
Ozæna, 701.

P

Pachymeningitis hemorrhagica interna, 152.
Padgett, Hazel, general anæsthesia, 459.
Page, Charles E., drugs and heart failure, 783.
Painful dentition, 700.
Palpation, subclavicular, diagnostic value of, 127.
Pan-American Medical Congress, 18, 50, 272, 274, 277, 304, 306, 331, 335, 336, 364, 402; Section of Diseases of Mind and Nervous System, 378, 445; of General Medicine, 341, 408; of General Surgery, 337, 373; of Gynecology and Abdominal Surgery, 408, 437; of Hygiene, Climatology, and Demography, 371, 434, 474, 501, 540; of Laryngology, 344, 409, 435; of Marine Hygiene and Quarantine, 372; of Obstetrics, 368, 406, 444; excursion to Rome, 117; notice to contributors, 116; official delegates to, 148; special tour of foreign delegates of, 365; the second, 399; visitors to, 148.
Pancreas, cyst of, 801, 824; supernumerary, 155.
Pancreotomy, 801, 824.
Paraldehyd in alcoholism, 711.
Paralysis agitans, pathology of, 300; atrophic, 280; importance of early attention to disabilities caused by infantile, 693; infantile, orthopedic treatment of, 374; spinal, of syphilitic origin, 560.
Paranoia, what is, 114.
Parésis, general, intercurrent disease in, 152; relation of syphilis to general, 741.
Paretic dementia vs. syphilitic cerebral and spinal disease, 445.
Parish doctor in Greece, 64.
Paris, medical faculty puzzled, 244; medical journals in, 148; a new surgical institute for, 844.
Park, Surgeon-Major, 657.
Park, Roswell, primary sarcoma of the tonsils, two cases of external pharyngotomy, 260.
Parke, Surgeon-General, death of, 432; Stanley's tribute to, 532.
Parker, W. W., high fees and low fees, 126.
Parotid gland, extirpation of diseased, 671.
Parturition, aids to easy, 370.
Pasteur Institute, patients under treatment at, 212.
Pasteur, Professor, 399.
Patent medicines, to regulate character of, 118.
Pathogenic bacteria, 662; removal of, from drinking-water by sand filtration, 663.
Patterson, J. A., therapeutics of resorcin, 80.
Pease, Charles G., emergency treatment of odontalgia: a criticism, 684.
Peck, Edward S., the dietetic and hygienic management of certain types of ocular diseases, 737.
Pedodynamometer, a new, 219.
Pedology, 244.
Pelvic abscess, 361; with encysted dropsy, 622; disease, plea for non-operative treatment of, 540; inflammatory diseases, inflammation of, 728.
Pelvic organs, one hundred operations for structural disease of, 442; prolapse of, 53.
Pelvic surgery, methods in, 25.
Pelvis, Mexican and European, compared, 368.
Pemphigus, 765.
Pencils, danger in, 466.
Penis, tertiary lesions of, 29.
Pennsylvania State Medical Law, 118.
Pension surgeon, 469
Pental, 29; as anæsthetic, 718.
Peptone, reconverted into albumin, 43.
Pericarditis, purulent, 361; treated by ice-bag, 208; with valvular lesions, 698.
Perineal incision, bilateral, for phosphatic calculi, 377.
Perineum, Martin's operation on, 109; superficial laceration of female, 357; tuberculosis of, 632.
Peritoneal cavity, hydrogen dioxide in, 460; viscera, surgical impunity of, 56.
Peritonitis, best treatment, 28; gonorrhœal, in the male, 527; pelvic, 250; propriety of operative measures in, 26; treatment of tuberculous, 605.
Perityphlitis, medical treatment of, 213.
Perleche, 428.
Pertussis, treatment of, 28.
Peruvian balsam, 829
Pestilential conditions, 540.
Peter, Charles Felix Michael, death of, 18.
Peters, the late Dr. John C., 564, 693, 723, 755; tribute to, 595.
Peterson, Frederick, the relation of syphilis to general paresis, 741; case of acromegaly combined with syringomyelia, 391.
Phagocytosis, significance of, 101.
Pharmacy, human body in, 606.
Pharyngeal curette, a new, 415.
Phenacetin, 244
Phenacetine, 607.
Phenol-salyl, 238.
Phenyl cocain, 607.
Philadelphia County Medical Society and

nostrums, 595; bequest to hospital, 182; quarantine 146.
Phillippo, J. C., electrocution, 286; the late, 756.
Phillips, W. C., a modified electrical head illuminator, 64.
Phlegmon of neck, special form of, 330.
Phorotone, 508.
Phthisis, clinical aspects of fibroid, 840; coughing in, made easy, 506; early localization of, to apex of lung, 208; heredity in, 287; rosin-weed for dyspnœa of, 77; supraclavicular inspiratory depression in early, 718; treatment of, 809.
Physical culture, 323.
Physician, the, and hard times, 456; convicted of murder, 20; delicate compliment to a skilful, 213; exempted from jury duty, 117; the best confessor, 736; the celebrated, 721.
Physicians stand by each other, 50; alleged misconduct of, 366; three kinds of, 19; why they do not share the honors of the world, 723.
Physiology, experimental and the human subject, 400.
Picrotoxin and strychnine, 608.
Pilocarpine in threatened mania, 64.
Pituitary gland, destruction of, 47.
Placenta, adherent, 28; prævia, conservative Cæsarean section for, 787; rapid dilatation of os uteri in, 406; study of, 369; with antipartum infection, 424.
Plaster-of-Paris dressings, knife for removing, 159; hammock apparatus for applying, 847.
Plaster jacket, technique of jacket, 375.
Pleural effusions, multiloculated, 527.
Pleuritis, aspiration in acute, 21.
Pleurisy, differential diagnosis of, 534; factors of, 534; pathology in chronic progressive, leading to recovery, 534.
Plummer George C., death of, 212.
Pneumonectomy, 361.
Pneumonia, 471; digitalis treatment of, 532; how an epidemic was checked, 664; a new early physical diagnostic sign of croupous, 493; present treatment of, 793; treated in St. Francis' Hospital, 1.
Poems, two little, 146.
Politics, doctors in, 351.
Politzer, Adam, 86.
Poliomyelitis, acute, in Boston, 724.
Polydactia, hereditary, 500.
Pond, Edward M., denuded cranium, 772.
Poor man's dietary and its chemical equivalent, 703; doctor, a plea for, 753.
Porro vs. Cæsarean section, 25.
Post nasal plugging, dangers of, 485.
Post-partum appendicitis, 14.
Posture, as a cause of uterine displacement, 443.
Potain, Professor, 657.
Potassium bichromate as an expectorant, 209; permanganate for urinary tract, 828.
Pott's disease, improved apparatus for, 373; of spine, early diagnosis and treatment of, 171; prognosis of, 31; recumbency in, 339.
Pozzi, Professor, 86, 690; in Cleveland, 562.
Pregnancy, abdomino peritoneal, 90; ectopic, 54; extra-uterine, 24, 54, 314; extra-uterine treatment of, after viability of child, 409; hemorrhages of, 368; study of blood in, 369; strychnine during, as aid to labor, 495; toxæmia of, 759.
Pregnant women, longings of, 528.
Premature labor, induction of, 369.
Presbyterian Hospital, refused to send an ambulance, 820.
Preventive medicine, need of research in, 475
Prince, A. E., prevention of blindness from ophthalmic neonatorum through treatment and legislation, 257.
Princeton, medical college at, 469.
Prize, the Samuel D. Gross, 724.
Probe, a new lachrymal, 318.
Procidentia uteri, complicated by pregnancy, 234; in pregnant women, 81.
Profession and Managing Boards, 818.
Progressive muscular atrophy, 216.
Proper pride, 128.
Prostate, castration for hypertrophied, 701; enlarged, 700; total extirpation, 526; tuberculosis of, 701.
Prostatectomy, hemorrhage after suprapubic, 700.
Prostatic pathology, some heresies regarding, 635.
Prostatitis, ichthyol suppositories in, 495.
Protestant Hospital Association of Duluth, 433.
Pruritis, 473, 765; treatment of, 473.
Psoriasis, 506, 765.
Psychical contagion in schools, 622.
Ptomaines, erroneous ideas on, 95.
Public Health Bill, 722; of Academy of Medicine, 592.
Puerperal blindness, 540; infection, 444; women, typhoid fever in, 209.
Puff-ball, hæmostatic properties of, 143.
Pulmonary cavities, surgical treatment of, 534.
Pulmonary syphilis, 15.
Pulse, apoplectic, its treatment, 347.
Pulsus paradoxus in acute laryngitis, 144.
Pyelitis, calcareous, 701.
Pyle, J. S., abdominal hysterectomy with clamps, 156; an operation on an interesting case of cystic degeneration of the thyroid gland, 581; emptying the uterine cavity by artificial dilatation, 355; new splint for fractures of femur without confining patients to bed, 190.
Pylorectomy, 312.
Pyrexia in acute anæmia, 269.
Pyodermitis, treatment of, 687.
Pyosalpinx, conservative treatment of, 728.

Q

Quacks, Congress of, 820.
Quarantine, Mr. Hart on, 529; international, uniformity in, 501; regulations, new, 334.
Queen and hospitals, 563.
Queen, Mary, medicines in days of, 320; Victoria, 243.
Quinine, chlorhydrosulphate, 28.
Quinine, idiosyncrasy in the action of, 319; non bitter, 506.
Quinsy, and its treatment by early incision, 549.

R

Rabies in India, 52.
Radius, ordinary fracture at lower extremity of, 361; regeneration of, after removal for osteo-sarcoma, 717.
Rae, John, death of, 214.
Railway spine, 287; prognosis of, 378.
Rake, Beaven, the question of the communicability of leprosy, 705.
Rectal strictures, new treatment for, 88; ulceration, etiology, diagnosis, and treatment, 634.
Rectum, complete prolapse of, amputation, 756; resection of, with transverse separation of sacrum, 687; stricture of, of puerperal origin, 264.
Red Cross and the projected Samaritan Union, 307; to the front, 530.
Reflex, patella, related with ocular reflexes in paralysis of insane, 184.
Refraction and accommodation, determination of, 395.
Reich, A., pyrexia in acute anæmia, 269.
Relations, reciprocal, between medical board and board of managers of hospitals, 241.
Remittent fever, study of prolonged, 342.
Renal calculus, a large, 827; tuberculosis, 591.
Resorcin, 764; in gastric ulcer, 28; therapeutics of, 80
Respiratory passages, bacteria of, 361.
Restrictions unnecessary in surgery, 56.
Retinitis punctata albescens, 186.
Revoked charters, 147.
Rheumatic iritis, 700.
Rheumatic joint affections, bacteriology of chronic, 389.
Rheumatic salve for pains, 319.
Rheumatism, acute, 765; salophen in, 141; affecting the nervous system, 215; and arterio-sclerosis, 461; and heer, 20; rare forms of, 538, 609; salicylate of lithia in, 700; treatment of acute and chronic, 506.
Rhinitis, acute, 28; dry, 764; hypertrophic, as cause of aphonia, 684.
Rhinoscleroma, case of, 471.
Richardson, J. B, a plea for slow and gradual exhibition of anæsthetics, 815; extirpation of diseased parotid gland, 671.
Richardson, memorial of Tulane University, 848.
Robbing doctors' offices, 656.
Robinson, Beverley, treatment of dyspnœa in phthisis by rosin-weed, 77.
Robinson, F. Byron, operative treatment of uterine prolapse, 456.
Robinson, Paul Skiff, case of hæmatoma of the vulva, 719.
Rockwell, A. D., the treatment of exophthalmic goitre based on forty-five consecutive cases, 417.
Rodman, Charles S., granite chip impacted in the auditory canal and tympanic cavity, 425; improved method for relief of symblepharon, 127.
Rome Congress, postponement of, 211.
Rosahnsky, H., birth in the coffin, 299.
Rose, A., methylene blue as a remedy against diphtheria, 267.
Rosenberg, H. L., persistent singultus, 425.
Rosenstirn, Julius, lipoma of the tongue, multiple symmetrical lipoma and their etiology, 385.
Rosin-weed in dyspnœa of phthisis, 77.
Ross, James, a significant symptom of aortic aneurism, 719.
Ross, William H., case of sarcoma of cervical spinal cord, autopsy, 193.
Rotary lateral curvature, 339.
Rice, Charles O., marriage of, 563.
Richards, Thomas J, death of, 468.
Richardson, J. B., extirpation of diseased parotid gland, 671.
Ring, burial of, beneath skin of finger, 584.
Ring, F. W., an ocular mask, 575.
Ross, J. W., suppression of urine for twelve days, recovery, 815.
Royal College of Physicians, 820.
Rugh, J. P., a new and rapid method of anæsthesia, 671.
Rush Medical College, four full courses in, 819.
Russell, William L., acute iodism, 207.
Russia, first experimental inoculation in, 116; medical fees in, 657; mortality in, 736; physician to Empress of, 595; medico-literary activity in, 735.
Ruth, C. E., determination of stomach end of divided intestine, 93.
Ryerson, G. Sterling, 147.

S

Safety-pin swallowed, 176, 298.
Salacetol, in diarrhœa, 750.
Salicrup, Pedro T., yellow fever and its treatment, 137.
Salicylate of bismuth in infantile diarrhœa, 29.
Saline enemata, utility of, in hemorrhage, 750.
Saloon, a "church," 656.
Salophen, in acute rheumatism, 141.
Salpingitis, as cause of pelvic inflammations, 250; complications of, 251.
Salt solutions, infusion of nutritive, in refusal or inability to take food, 762.
Salts, inorganic, as food and stimulant, 273.
San Francisco, a physician's gift to, 690; new hospital at, 595.
Sanitation, early, 576; fruits of, 96; how women can promote public, 569; new departure in, 17.
Sanitary knowledge, progress of, among women of England, 569.
Sanitary motes and beams, 434.
Sanitary precautions, 501; work in St. Louis, 474.

Sarcoma, diffuse, of uterine mucous membrane, 763; extirpation of endocranial, 559; of choroid, 184; of eyelid, 184; of naso-pharynx, 410; of thigh, 89; of tonsil removed by external incision, 301; primary sarcoma of, 260.
Savage, Charles C., a response from Demilt Dispensary, 767.
Scabies, 765.
Scalp, impetigo of, 765.
Scarlet fever, 795; immunity from, by inoculation of blood serum, 466; in London, 52.
Sciatica, 700; methyl chloride in, 699; treatment of, 4, 462.
Scientists, a common tongue for, 688.
School buildings, construction of, 323.
School children, defective and sickly among, 160.
School hygiene, 323.
Schüler, Max, bacteriological researches into the etiology of the so-called chronic rheumatic joint affections, 389.
Schwarzschild, H. Davison, a combined lachrymal gouge, 702.
Scleroderma, a case of circumscribed, 471.
Scoliosis, gymnastic apparatus for, 375.
Scopolaminum, hydrochloricum, 208.
Scotch douche, 29.
Scott, N. S., rectal stricture of puerperal origin relieved by laparotomy, 264.
Scrofuloderma, 765.
Scrotum, eczema of, 765.
Sea-sickness, modern treatment of, 480; therapeutics of, 16.
Semilunar cartilages, operation for dislocated, 840.
Seminal incontinence, treatment of, 457.
Septicæmia, iodine trichloride hypodermatically in puerperal, 723; puerperal, 313.
Sero-therapy, 625.
Serum injections in tetanus, 672.
Sewage disposal, 568.
Sewage farm system, 112.
Sex, determination of, 723, 787.
Shamelessness, extraordinary, 831.
Ship-owners and ships' surgeons, 786.
Shock, 250.
Shoulder-joint, recurrent dislocations of, 396.
Shrady, George F., a simple method of closing large operation wounds by sliding skin flaps, 717.
Sick, do they ever sneeze? 817.
Silkworm gut in tissues three years, 177.
Silver nitrate in gastric ulcer, 31.
Silver nitrate in lupus, 239.
Simmons, Charles E., suit of, 84.
Sims's speculum, a new holder for, 509.
Singing methods, effects of improper, on the voice, 435.
Singultus, 699; persistent, 425; relieved by lavage of stomach, 234, 338, 426, 542.
Skin disease, a newly described, 794; new remedies in, 544; suggestion for treatment of, 735.
Skin grafting, excellent results of, 349; in denuded cranium, 772.
Skin grafts, transplantation of, to eyelid, 375; bandage for protection of, 375.
Skin, malignant growths of, 294.
Skull, angular gouge for operations on, 311; depressed fracture of, 777.
Sleep, or allied conditions, some peculiar forms of, 505.
Small intestine, rupture of, 87.
Small-pox, five new cases of, 333.
Smart, Charles, first aid to injured, from army standpoint, 71.
Smith, Andrew H., discharge from middle ear, temporarily arrested by the removal of adenoid growths from the pharynx, 235.
Smith, A. Lapthorn, cerebral anæmia and puerperal eclampsia, 572.
Snellen's method for symblepharon, 361.
Sneezing for hysteria, 79.
Sodium biborate in epilepsy, 192.
Sodium bicarbonate in large doses, 586.
Sodium phosphate in two per cent. solution, 505; tetraboricum, neutral in ear disease, 28.
Somerville, W. G., insolation, 74.
Somnambulist, a, 333.
Sophocles, skull of, found in Greece, 306.
Southern Surgical and Gynecological Association, 467, 627, 728, 732, 757.
Spastic paralysis, cerebral, in adults, 378.
Spottswood, Dillon J., puerperal fever and erysipelas in infant, 14.
Specialist, the successful, 192.
Specialism, the dangers of automatic, 843.
Specialties in medicine and surgery, 477.
Speier, H., silkworm gut in tissues for three years, 177.
Spelling made hideous, 690.
Spence, Arnot, treatment of pneumonia in St. Francis' Hospital, 1.
Sphincter, formation of a new, after extirpation of the rectum, 653.
Sphincterplasty, 749.
Spier, E. Fleet's suit against the city of Brooklyn, 469.
Spinal cord, cervical, sarcoma of, 193; degeneration and pernicious anæmia, 526; lesions of, with and without fracture, 554.
Spine, cervical, fracture of, 182; railway, 287; rotary, lateral curvature of, 774.
Spleen, accessory, in tail of pancreas, 763; in a new rôle, 300; rôle of, in immunity, 213; supernumerary, a case of, 320.
Splenic abscess, successful operation for, in a child, 718.
Splint headings, 338.
Splints, new material for, 88.
Spratling, W. P., inflammation of upper air-passages caused by inhalation of Persian insect powder, 584; the origin of the non-restraint system in the treatment of the insane, 683; poisoning from overdose of codein, 87.
Squint, case of convergent, 227.
St. John's Guild, 20, 83.
St. Lawrence County Medical Society, 499.
St. Louis, sanitary work in, 474.
St. Luke's Hospital, 596, 819.
Stanley, Charles Wesley, death of, 658.
Stanton, Richard J., report on seventy cases of intubation, 673.
Stapedectomy, 150.
Stapes, removal of, 150.
Staten Island, hospital for, 754.
Statistical bent, patient suffering from, 704.
Stebbins, Roswell O., painless dentistry, 524.
Stedman, Thomas L., 468.
Sterility due to tubal and ovarian disease, 761; treatment of, 349.
Stewart, W. W., a mural dermoid cyst of the uterus, 648; cocaine and its use in abdominal surgery, 749.
State Boards of Examiners, influence of, on medical teaching, 640; Board of Health, 180; money expended for, 116.
State hospitals, central supervision of, 816.
Stoechiology, 182.
Stomach, bacteria of, 269; carcinoma of, 698, 825; diseases, 699; surgical treatment of ulcer of, 309; treatment of some irritable conditions of, 812; ulcer, nausea in, 29.
Stone in bladder, experience in operative treatment of, 732.
Straight, Howard S., a case of aphonia due to hypertrophic rhinitis, 684.
Stramonium intoxication, case of, 525.
Streeter, R. M., death of, 212.
Streptococcus pneumonicæ in cerebro-spinal meningitis, 795.
Strychnia, 793.
Strychnine and picrotoxine, 608; during pregnancy as an aid to labor, 495; in alcoholism, 711.
Subclavian, aneurism of, 310.
Suggestion, a strange, 768.
Suicide and evolution, intoxicants and narcotics, 845.
Sullivan, Daniel F., open safety-pin swallowed, 176.
Sun in surgery, 332.
Suppuration of middle ear, with brain and lung complications, 149.
Supra-renal capsules, function of, 429.
Surgeon's nerve, a, 672.
Surgery, canons in, 249; the sun in, 332.
Surgical advances, relation of, to conservative obstetrics, 408; principles, evolution of, 248.
Suspensio uteri, 55.
Symphyseotomy, 121, 408, 839; case of, 582, 679; the first on the Pacific coast, 182.
Symblepharon, improved method for relief of, 127; relief of, 214; Snellen's method for, 361.
Syphilides, gummy, of lower extremities, 361.
Syphilis, affections of testicle in hereditary, 590; and tabes, 219; antiquity of, 56; as infectious disease, 587; date of introduction of, into Europe, 690; diagnosis of hereditary, 273; hypodermatic treatment of, 48; injections of blood serum in, 147; jaundice in, 237; late ocular manifestations of, 506; mercurial flannels in the treatment of, 505; of auditory canal, 232; pulmonary, 15; relation of, to general paresis, 741; skin lesions of, 559; tertiary, 791; testicle in hereditary, 664; treated by simple application of mercurial ointment, 590.
Syphiloma of cerebellum, 585.
Syphilitic deposits in liver and lungs, 152; infection as vehicle of tuberculosis, 662.
Syringomyelia, with acromegaly, 391.

T

Tabes and syphilis, 219.
Tabes dorsalis, versus syphilitic, cerebral, and spinal disease, 445.
Tachycardia, fatal case of essential, 631.
Tachadynamometer, showing influence of chloroform on labor, 590.
Taeniifuge, a new, 27.
Talipes equino varus, apparatus for correction of, 374; incurability of advanced and extreme cases of, 633.
Talmey, B. S., case of ileus cured by laparotomy, 622.
Tampon, intra-uterine, 408.
Tannin in tea, 849.
Tape-worm, 699.
Tartar emetic in exfoliative dermatitis, 765.
Taylor, R. W., dinner to, 756.
Teft, William, the recrudescence of leprosy and its causation, 286.

Traumatic nervous diseases, simulation in, 221.
Treatment, common sense in, 597.
Trendelenberg's posture after cœliotomy, caution in use of, 525.
Trephining in the Stone Age, 400.
Trichinæ, retrograde changes in, 46.
Tricophytosis, 700.
Trional as hypnotic, 351; and tetronal, 589.
Tripe, digestibility of, 480.
Tri-State Medical Society, 467.
Tropacocaine, value of, 799.
Trudeau, Dr.'s, house burned, 787.
Tubercular laryngitis, treatment in Colorado, 436; ulceration of larynx treated by Krause's method, 437.
Tuberculin, 532.
Tuberculosis, 249, 291; testicle, 701; and the food supply, 662; and Health Department, 817; and leprosy, 502; bovine, 59; contagiousness of, 831; conveyed by syphilitic infection, 662; gastric manifestations of, 839; general, 155; notification of, 640; of larynx, 765; of peritoneum, 632; of prostate, 701; operative treatment of peritoneal, 587; peritonitis, treatment of, 605; practical measures in prevention of, 501; renal, 591; report of committee on restriction and prevention of, 567; simulating lupus erythematosus, 472.
Tuft's College Medical School, 819.
Tumor albus of knee, history of treatment of, 660.
Tumors of dura, surgical intervention in, 47.
Twice told tale, a, 303.
Tympanic perforations, small, 361.
Typhlitis, 21.
Typhlotomy, temporary, for obstruction of large intestine, 589.
Typhoid fever, 699; and Brand bath, 764; and raw oysters, 754; at Berlin, 532; autumnal, 332; bacillus, yeast destroys the, 239; beta naphthol in, 28; boric acid in, 27; cool bath in, 281; efficacy of vaccinia after, 540; empyema in, 461; its de novo origin, 328, 507; diagnosis of, 416; guaiacol in, 423; in Chicago, 841; inoculations in, 672; in puerperal women, 209; Mexican remedy for, 287; origin and dissemination of, 568; present treatment of, 793; sulpho-carbolate of zinc in, 28; treatment of, with blood of immune persons, 734; unusual features in, 342.
Typhus bacillus, discovery of, in New York City, 85, 530.

U

Ulcers, 765.
Ulcer, silver nitrate in gastric, 31; resorcin, 28.
Ulcers, cancroid, treatment of, by topical application, 534.
Umbilical hemorrhage in infants, 424.
University extension, 85.
Uræmia, acute, 91; kidney extract in, 270.
Urea, excretion of, in certain surgical diseases, 428.
Ureter, potency of, after division, 349; stricture of, 57; surgery of, 87.
Ureterectomy, 87, 463.
Ureteretis membranacea, 718.
Urethra, artificial, in chronic prostatic enlargement, 87; broken catheter in, 234; traumatism of, 700.
Urethral canal, sterilization of, 358; injections, value of, in gonorrhœa, 263; strictures, multiple, of gonorrhœal origin, 370.
Urethritis, catarrhal, in small boys, 701; chronic, 700; chronic, rôle of posterior urethra in, 132.
Urinary conditions, relations of, to results of operative surgery, 441; infection, systemic, 700.
Urine changes in myxœdema during thyroid feeding, 795; passage of fat into, 461; significance and detection of carbo-hydrates in, 21; suppression of, for twelve days, recovery, 815; toxicity of, 114.
Uric acid, blood changes produced by, 384; gravel, 700; significance of excessive secretion of, 812.
Uterine appendages, diseased, 121; treatment of diseased, 283, 633; carcinoma, 361; cavity, emptying of, by artificial dilatation, 355; fibroid, 121; new operation for, 53; pedunculated, 121, 630; present status of treatment of, 632; treatment of, 828; flexions, treatment of, 27; hemorrhage, controlled by electrolysis, 791; traumatic, 394; medicaments, new applicator for introducing, 88; prolapse, operative treatment of, 456.
Uterus and ovary, sarcoma of, 154; cavernous angioma of, 439; dangers following extirpation of, per vaginam, 588; diffuse sarcoma of mucous membrane of, 763; early diagnosis and electrical treatment of fibroids of, 682; extirpation of, without ligatures, 301; in old woman, 128; treated by abdominal section, 176; mural dermoid cyst of, 648; plea for early diagnosis and electrical treatment of fibromatous, 439; removal of, by abdominal hysterectomy, 4; removal of, for fibroids, 25; rudimentary, 790; total extirpation of fibromatous, 437; vagino-fixation of, 782; ventral fixation of, 314.
Utica Asylum, managers of, and State commissioners in lunacy, 755.

V

Vaccination, 743; wholesale, 562; statistics of, in 5,866 cases, 416.
Vaccine lymph, preservation of, in hot weather, 239.
Vaccinia, efficacy of, after typhoid fever, 540.
Vagina, rudimentary, 790.
Vaginal discharges, significance of, 330; route, as compared with abdominal, for removal of pelvic viscera, 731.
Vaginitis, diphtheritic, 152.
Value of close observation of other men's work, 632.
Valvular insufficiency, functional, 749.
Vanderbilt clinic and small-pox, 432.
Vanderpoel, W. B., albuminuria without manifest renal lesion, 611.
Van Vranken, Gilbert, the use of strychnine and paraldehyde in alcoholism, 711.
Varicocele, operation for, 827.
Varicose veins, new operation for, 57.
Varnish, an antiseptic, 768.
Vas deferens, patency of, after division, 349.
Vermiform appendix, carcinoma of, 825.
Vertical diplopia test untrustworthy, 185.
Veratrum viride, 29.
Vibration, mechanical, in treatment of disease, 695.
Victoria disaster, a possible explanation of, 317.
Vinca minor for diphtheria, 96.
Viraginity and effemination, 359.
Virchow, professor, 657; successor to, 724.
Virginia Medical Society, 212.
Vision, necessity of perfect, in education of the young, 566.
Visual image, suppression of, 186.
Vitreous, removal of steel from, by magnet, 186.
Voice regained after extirpation of larynx, 60.
Vomer necrosed, exostosis of, 699.
Von Helmholtz, professor, 469.
Von Esmarch, professor, 20,000 operations of, 118.
Von Wedekind, L. L., the use of aconite in the treatment of tetanus, 420.
Vought, Walter, death of, 433, 469, 562.
Vulva, hæmatoma of, 121, 719.

W

Wagner, Clinton, case of acute idiopathic glossitis, 523.
Waldstein, Louis, new apparatus for sterilization of milk, 140.
Walrus fin hand, 835.
Warner, F. M., proper feeding of infants, 78.
Washington, new medical college in, 657; State board of examiners, 433.
Waste, disposition of animal and vegetable, in Milwaukee, 569.
Water-supply in country districts, 762; not appreciated, 181.
Waxham, Dr. F. E., Chicago, 433.
Weariness, physiology of, 427.
Weaver, John E., the emergency treatment of toothache, 623; the treatment of gonorrhœa, 426.
Weber, Leonard, clinical experiments with creosote in the management of inoperable cases of surgical kidney, 681; further contributions to the pathology and therapy of neurasthenia spinalis, 321.
Weber, W. C., astasia-abasia, 808.
Wedding delayed by misfit leg, 466.
Weichselbaum, Dr. Anton, 399.
Weir, James, Jr., viraginity and effemination, 359.
Weir, R. F., carcinoma of duodenal papilla; pancreatic cyst, 801, 874.
Welch, Geo. T, therapeutical superstition, 33.
Wendt, E. C., Franzenbad, the Bohemian spa, 105.
Wells, Walter S., traumatic uterine hemorrhage, 394.
Western Reserve medical school, 366.
West Virginia medical society, 432.
Westlake, Albert, correction of deformities of the oral region, 644.
White, William T., death of, 401.
Whooping cough, bromoform in, 28, 495; to abort, 29.
Wiggin, Frederick H., hydrogen dioxide in the peritoneal cavity, 460.
Will, an ante-mortem, 160.
Wisdom, a bit of official, 734.

Wolf, Matthias, death of, 243.
Won his case, 595.
Woman—what she can do, 448; who first opened, for diseases of her appendages, 723.
Woman's Hospital, vacancies on house staff of, 819.
Women doctors, forty years ago, 576.
Women—should they smoke, 464; students at French faculties, 116.
Wools, to detect color blindness, 185.
Work, Hubert, typhoid fever, its de novo origin, 329.
World's Fair, emergency hospital at, 657; health department exhibit, 444; disposal of garbage and waste of, 569; medical aspect of, 117, 124; surgical exhibit at, 398.
Worthington, J. M., doctors in politics, 351.
Wry neck, 828.
Wyeth's method in hip amputations, 757.

Y

Yeast destroys the typhoid bacillus, 239.
Yellow fever, 242, 304; at Brunswick, 397. 531, 562, 595; at Pensacola, 212; contribution to study of, from medico-geographical standpoint, 664; epidemic, 469; immunizing for, 464, 508; treatment of, 137.
Younghusband, Dr. L., 820.

Z

Zinc sulpho-carbolate in typhoid, 28.
Zeisler, Joseph, the case of impetigo herpetiformis, 447.
Zoothermic institute at Rome, 563.
